Abstract

The 718,122 base pair sequence of the *Escherichia coli* K-12 genome corresponding to the region from 12.7 to 28.0 minutes on the genetic map is described. This region contains at least 681 potential open reading frames, of which 277 (41%) have been previously identified, 147 (22%) are homologous to other known genes, 139 (20%) are identical or similar to the hypothetical genes registered in databases, and the remaining 118 (17%) do not show a significant similarity to any other gene. In this region, we assigned a cluster of *cit* genes encoding multienzyme citrate lyase, two clusters of fimbrial genes and a set of lysogenic phage genes encoding integrase, excisionase and repressor in the e14 genetic element. In addition, a new valine tRNA gene, designated *valZ*, and a family of long directly repeated sequences, LDR-A, -B and -C, were found.

Key words: *Escherichia coli* K12; genome sequence; ORF analysis

1. Introduction

As a model organism, *Escherichia coli* has been playing significant roles in the establishment of a number of basic concepts in molecular biology, and the enormous amount of data accumulated to date has contributed to the understanding of a variety of cellular processes of not only *E. coli* but also other organisms.¹ In addition, determination of the whole genome sequence of *E. coli* is undoubtedly awaited for further insight into various bio-

logical phenomena.

Until now, the complete DNA sequences from two organisms, *Haemophilus influenzae*² and *Mycoplasma genitalium*,³ were reported, and sequencing of several other prokaryotic and eucaryotic genomes are now in progress. In *E. coli*, a contiguous sequence covering about 65% of the whole genome has been determined.⁴ The *E. coli* genome project in Japan was started in 1989 to analyze the sequence of the *E. coli* genome from 0 minutes in a clockwise direction. So far, the DNA sequences of the 0–2.1⁵ and 2.1–4.1 min⁶ regions on the genetic map were determined and published previously. Subsequently, the

* To whom correspondence should be addressed. Tel. +81-564-55-7690

entire sequence from 4.1 to 12.7 min was determined and the data of a part of the region (4.1 min to 6.0) registered in the DDBJ database. In April 1995, we reorganized a new group for analysis of the DNA sequence of the region from 13 to 50 minutes using a new protocol. In addition, the team headed by Blattner in the United States has determined a contiguous sequence from 0 (100) to 76 minutes in counterclockwise.^{7–12} They have also registered the sequence data of the 76–60 min region in GenBank. In this paper, we describe a 718-kb DNA sequence of the region spanning from 12.7 min to 28.0 min on the genetic map.

2. Materials and Methods

2.1. DNA source

2.1.1. Preparation of bacterial DNA from Kohara's clones¹³

DNA samples used in this experiment were prepared from Kohara's library, in which DNA fragments of *E. coli* K-12 W3110¹⁴ were cloned in phage lambda. Individual phage clones were grown in 20 ml of NZCYM medium on host W3110, and precipitated by the addition of polyethylene glycol (PEG) #6000. Total phage DNA containing each bacterial DNA fragment was purified with a QIAGEN lambda kit (Qiagen GmbH, Hilden, Germany). Bacterial DNA in each lambda clone was amplified by polymerase chain reaction (PCR) using a GeneAmp XL PCR kit (Perkin-Elmer/Applied Biosystems Division, Norwalk, CT, USA) with two primers, primer 1 (5'-ACAGTCGGTCCGGCAGTACAATGGATTACC-3', residing upstream of 678 base pair (bp) from the *Bam*H cloning site on the left arm of lambda EMBL4) and primer 2 (5'-GCAACCTGCAACGTAT-TGAGCGCAAGAACGCGC-3', residing downstream of 640 bp remote from the *Bam*H cloning site on the right arm).¹⁵ After electrophoresis on a 0.4% agarose gel, the PCR product was purified by EASYTRAP (Takara Shuzo Co., Kyoto, Japan).

2.1.2. Sonication, size selection and cloning of the *E. coli* DNA

Five micrograms of PCR DNA was sonicated for 10–20 sec with a Bransonic Sonifier (Heat Systems, Farmingdale, NY, USA). The sonicated DNA was blunt-ended using a DNA blunting kit (Takara Shuzo Co.) and fractionated by 6% polyacrylamide gel electrophoresis. DNA fragments of 0.6 ~ 2 kb in length were excised from the gel and eluted by MG elution buffer (500 mM ammonium acetate, 10 mM Magnesium acetate, 1 mM EDTA, 0.1% (W/V) SDS) for overnight at 37°C. The recovered DNA was ligated with the *Sma*I site of vector M13mp19

DNA,¹⁶ which was previously treated with bacterial alkaline phosphatase, and introduced into TG1¹⁷ or JM109¹⁶ competent cells with an electroporator. The cells were plated on LB plates containing X-gal and IPTG to form plaques. More than 250 independent white plaques per lambda clone were isolated.

2.1.3. Purification of the M13 single-stranded DNA

M13 phage clones isolated were grown in 2 × YT medium¹⁷ for 8 hr on host TG1 or JM109. Phage particles were collected from 2 ml of culture supernatant by PEG precipitation and single-stranded DNA (ssDNA) was prepared by phenol-chloroform extraction followed by ethanol precipitation or by an automatic plasmid isolation system (PI-100 Σ; Kurabo, Osaka, Japan).

2.2. DNA sequencing

A DNA sequence kit (Dye primer cycle sequencing ready reaction -21M13; Perkin Elmer/Applied Biosystems Division) was used for Sanger dideoxy chain termination reactions. After termination of the reaction, a portion of the reaction mixtures was applied onto 373S or 377 DNA sequencers (Perkin Elmer/Applied Biosystems Division) and their DNA sequences were analyzed.

2.3. Sequence assembly and data analysis

The raw sequence data were assembled and edited using the two computer programs, Autoassembler of Perkin Elmer/Applied Biosystems Division and ATSQ of Software Co., Ltd., Tokyo, Japan. The programs BLAST and GeneMark¹⁸ were used to aid in identifying potential open reading frames (ORFs). Each ORF was compared to SWISS-PROT and PIR protein databases using BLAST.

2.4. Gap-filling with known sequences

The following four gaps were filled by the sequences registered in GenBank: 6.8-kb region between lambda clones #180 and #203, 1.8 kb between #223 and #225, 1.65 kb between #234 and #236, and 0.38 kb between #173 and #174. The last two clones were reported to be overlapped in the physical map,⁴ but we found that there was a gap between them. Other sequences reported in this work were newly determined.

3. Results and Discussion

3.1. Sequencing strategy

We determined a 718,122-bp sequence spanning the region from 12.7 to 28 min on the *E. coli* genetic map. The strategy for analysis of the *E. coli* genome was based on shotgun cloning and sequencing of the DNA fragments prepared from respective Kohara clones¹² followed by

assembly of random sequences using two computer programs, Autoassembler and ATSQ. Bacterial insert DNA (17 kb on average) in each lambda clone was amplified by a long PCR procedure¹⁵ and PCR products were randomly fragmented by sonication. DNA fragments ranging from 0.6 to 2.0 kb in size were isolated and sub-cloned in phage M13mp19¹⁶ as the vector. ssDNA was purified and used as the template for cycle sequencing with a universal primer (-21M13). When more than 250 random DNA fragments prepared from respective Kohara clones were sequenced, most sequences (98–99%) were assembled into one contiguous sequence. If gaps remained, additional M13 clones or PCR products amplified using appropriately designed synthetic primers encompassing the gaps were sequenced. For ambiguous bases, we sequenced additional M13 clones or PCR products amplified using appropriate M13 clone DNA as a template in reverse direction as well. Random short sequences derived from a Kohara clone were assembled into a contiguous sequence using the Autoassembler program. Then, the contiguous sequences thus obtained from respective Kohara clones were further assembled and edited by the ATSQ program. Under the experimental conditions, mean sequence redundancy was 7.2-fold and the overall accuracy of the contiguous sequence was estimated to be 99.99% by comparison with previously reported sequences and with overlapped sequences of two adjacent lambda clones.

3.2. Assignment of potential coding region

To assign ORFs, we first selected potential ORFs which were composed of more than 50 consecutive sense codons. All these ORFs were translated into amino acid sequences and then subjected to homology analysis against the SWISS-PROT (release 31) and PIR (release 44) protein databases using the BLASTP program. When ORFs to be examined showed more than 95% identity in sequence and consistency in amino acid length to known gene products, they were referred to as known genes. In the newly sequenced regions, ORFs with BLASTP scores of more than 100 were classified as either homologous or hypothetical according to their functions. When the functions of the reported ORFs or genes were known, the corresponding new ORFs were classified as homologous; when the functions of the reported ORFs were not known, the corresponding new ORFs were classified as hypothetical. The ORFs that could not be predicted by BLASTP were predicted either using the program GeneMark¹⁸ or visually. In the latter case, the possible NH₂-terminus of each predicted ORF was estimated by calculating the efficiency of the ribosome binding site for translation with a program developed by ourselves. These ORFs were classified as hypothetical as well. The nomenclature of the predicted ORFs was based on the consecutive numbers of ORFs found in

each Kohara clone; for example, the ORF designated as o162#1 was ORF number 1 in Kohara miniset clone 162. Specific sequences other than ORFs were checked by the FASTA program.

The ORFs predicted in the 12.7–28 min region on the linkage map are summarized in Table 1 and illustrated in the Supplement. We found at least 681 potential ORFs in this region. Among them, 277 ORFs (41%) were identical to known genes reported previously. One hundred and forty seven (22%) and 139 (20%) ORFs were identified as homologous and hypothetical genes, respectively. The rest of the ORFs (118, 17%) did not show a significant similarity to any other gene registered in the two databases.

3.3. Unique ORFs identified

In the sequence determined, we identified 9 genes, *nfbB* (nitrofurantoin sensitivity; 13.1 min), *rnk* (regulator of nucleoside diphosphate kinase 14.0), *gltI*, *K* and *L* genes (glutamate/aspartate transport system; 14.9 min), *mddA* (19.4 min), *ftsK* (filamentation; 20.3 min), *pqi* (paraquat inducible; 22.0 min), *torR* (regulator of trimethylamine oxide reductase; 23.0 min). The DNA or protein sequences of these genes were known but their locations were not identified.

The *lol* (*lplA*) gene (lipoate-protein ligase) and a part of its sequence had been localized to 99.6 min on the linkage map.⁴ However, we found an exactly identical sequence map position of the gene may be erroneous. The deduced amino acid sequence of o207#3 was found to be 70% identical to that of the putative transaldolase encoded by *talC* at 89.1 min. It has been reported that *E. coli* possesses at least two transaldolase genes, *talA* and *talB*, and the amino acid sequence of the *talA* gene product was 64% identical to that of the *talB* gene product.¹⁹ Comparison of amino acid sequence between o207#3 or *TalC* and *TalA* or *TalB*, however, showed only 11 to 14% identity. These results indicate that both o207#3 and *talC* were generated by duplication, and that they belong to a different family from that of *talA* and *talB*.

The amino acid sequences of two ORFs (o162#5 and o162#6) showed a high degree of similarity to *copS* and *copR* gene products of *Pseudomonas syringae*, respectively. Because CopS and CopR are sensor and transcription activator proteins of the two-component systems, respectively, o162#5 and o162#6 may be new members of the family.

The six ORFs located at 14.0–14.1 min showed a sequence similarity to a group of *cit* genes encoding citrate lyase or its related enzymes in *Klebsiella pneumoniae* and *Haemophilus influenzae*. In *E. coli*, citrate lyase has been shown to be a multienzyme complex built up from at least three different subunits (alpha, beta and

gamma).²⁰ However, the genes coding for these subunits have not been identified yet. The fact that the order of the six ORFs is identical to that of the *cit* genes in *H. influenzae* strongly suggests that these ORFs are likely to be the *cit* genes in *E. coli*. Moreover, it is interesting to note that a sequence of more than 20 kb covering the region from the *cit*-like gene cluster (14.1 min) to *mrdA* (*pbpA*; 14.5 min) is homologous to a sequence of about 13 kb from the *citG* to *pbp2* genes in *H. influenzae* with respect to genes and gene order, although a central portion of the region present in *E. coli* is not present in *H. influenzae*.

The *cde* gene (constitutive dam expression) is supposed to be a transcription regulator of the *dam* gene encoding DNA adenine methylase. The *cde* gene was reported to be located within the *lipB* gene (lipoate biosynthesis protein; 14.4 min) or between the *lipB* and *lipA* genes. Since there is only one ORF (o168#13) present in this spacer, and since it has motifs shared with the LysR transcriptional regulator family, this ORF probably corresponds to the *cde* gene. Likewise, o166#7 was found to have the LysR motifs. This might be the *leuJ* gene encoding a regulator of *leu* and *ilv* operons, because it mapped to around this locus.

At least two fimbrial gene clusters were found. One cluster contains three ORFs (o175#9, o175#10 and o175#11; 16.3 min), and the products of the first two genes are homologues of *E. coli* outer membrane chaperone protein PapD and usher protein PapC, respectively.

The other contains at least seven fimbrial genes (o221#5–#11; 21.7 min). This cluster also encodes a pair of chaperone- and usher-like proteins, o225#13 and #14 at 22.8 min probably encode cold shock proteins similar to CspF and CspB proteins, respectively.

A group of ORFs present in a 13-kb region spanning from 24.6 to 24.8 min showed a high degree of similarity in both sequence and organization to the *flg* (flagella) genes in *Salmonella typhimurium*, except the sequence of the *flgD* gene encoding a flagella basal-body rod modification protein. *E. coli* and *S. typhimurium* seem to have the same set of *flg* genes. In addition, downstream of the *flgMN* genes, there are two other genes (o233#6 and #7) which are almost identical to *Salmonella mviM* and *mviN* genes encoding virulence factors for mouse.

The e14 element (26.1 min) has been thought to be a cryptic prophage. Within the e14 region, three ORFs (o240#2, #3 and #4) are found to be homologues of integrase, excisionase and repressor in lysogenic phage P21. Probably, this putative repressor is inactivated during the process of SOS induction, and consequently, expression of the two genes results in excision of a 14.4-kb circular DNA.

3.4. Other futures

We found new long direct repeat sequences, termed LDR-A, -B and -C, at a spacer region between the *kdsA* and *chaA* genes at 27.7 min (Supplement). One repeat unit consists of 535 bp and 2.9 repeat units are present there. At least one homologous unit, termed LDR-D, is present at 73.4 min in *E. coli* and one similar unit is also located at 9 min in *S. typhimurium*.²¹

tRNA genes, IS elements and the RhsC element are located at the sites as reported (Fig. 1). Of the I7 tRNA genes identified, one located between the two lys-tRNA genes at 16.9 min seems to encode a new valine tRNA gene, named *valZ*, whose sequence is identical to that of *valT*. Repeated sequences (REP, ERIC and RSA) and *cis*-elements (DNA replication terminus; *Ter* and *Chi* sequences) are also indicated in Supplement.

Acknowledgments: We thank Dr. Y. Kohara for kindly providing all lambda clones used in the present experiment, Dr. N. Ogasawara for giving a valuable advice about the shotgun sequencing protocol and Dr. M. Borodovsky for kindly providing a program software, GeneMark. This work (H. M.) was supported in part by Grants-in-Aid for Scientific Research 04261101 from the Ministry of Education, Science, Sports and Culture, Japan.
