(Communicated by Christopher D. Sogge)

#### Abstract

We obtain nearly sharp estimates for the $L^{p}\left(\mathbb{R}^{2}\right)$ norms of certain convolution operators.

For $n \geq 1$ let $\lambda_{n}$ be the measure on $\mathbb{R}^{2}$ obtained by multiplying normalized arclength measure on $\{|x|=1\}$ by the oscillating factor $e^{i n \arg (x)}$. For $1 \leq p \leq \infty$, let $C(p, n)$ denote the norm of the operator $T_{n} f \doteq \lambda_{n} * f$ on $L^{p}\left(\mathbb{R}^{2}\right)$. The purpose of this note is to estimate the rate of decay of $C(p, n)$ as $n \rightarrow \infty$. By duality, it is enough to consider $p \geq 2$. Examples below will show that

$$
\begin{equation*}
C(p, n) \geq C(p) n^{-\frac{1}{6}-\frac{1}{3 p}} \quad \text { if } \quad 2 \leq p \leq 4 \tag{1}
\end{equation*}
$$

and

$$
\begin{equation*}
C(p, n) \geq C(p) n^{-\frac{1}{p}} \quad \text { if } \quad 4 \leq p \leq \infty \tag{2}
\end{equation*}
$$

On the other hand, we will observe that

$$
\begin{align*}
C(2, n) & \leq C n^{-\frac{1}{3}}  \tag{3}\\
C(\infty, n) & \leq C
\end{align*}
$$

and then prove the following result.
Theorem. There is a positive number a such that

$$
\begin{equation*}
C(4, n) \leq C n^{-\frac{1}{4}}(\log (n))^{a} . \tag{4}
\end{equation*}
$$

Interpolating (3) and (4) gives upper bounds for $C(p, n)$ which differ only by a power of $\log (n)$ from the lower bounds of (1) and (2), thus providing nearly sharp estimates for $C(p, n)$.

The above question naturally arises when considering the $L^{p}\left(\mathbb{R}^{3}\right)$ mapping properties of the operator $T$ given by convolution with respect to a compact piece of arclength measure on the helix

$$
t \rightarrow(\cos t, \sin t, t) .
$$

$T$ is an example of a folding Fourier integral operator in dimension 3, whose singular set is of dimension 1 . The sharp $L^{p} \rightarrow L^{2}$ mapping properties of $T$ were established by the first author in [O]. The operator $T_{n}$ arises when considering the

[^0]$L^{p}$ smoothing properties of $T$; that is, for which values of $\alpha_{p}$ is $|D|^{\alpha_{p}} T$ bounded on $L^{p}\left(\mathbb{R}^{3}\right)$. Since
$$
T\left(e^{-i n x_{3}} f\left(x_{1}, x_{2}\right)\right)=e^{-i n x_{3}}\left(T_{n} f\right)\left(x_{1}, x_{2}\right),
$$
the exponents in (1) and (2) give upper bounds on $\alpha_{p}$. In particular, the smoothing exponent for $T$ is less than that of averaging in $\mathbb{R}^{2}$ over the cubic $t \rightarrow\left(t, t^{3}\right)$, where the corresponding value of $\alpha_{p}$ is
\[

\alpha_{p}=\left\{$$
\begin{array}{lll}
\frac{1}{3} & \text { if } & 2 \leq p<3 \\
\frac{1}{p} & \text { if } & 3<p<\infty
\end{array}
$$\right.
\]

See, for example, $[\mathrm{SW}]$ or $[\mathrm{SS}]$. The authors would like to thank Chris Sogge for discussions which led to consideration of this question.

To see (2), apply the operator $T_{n} f \doteq \lambda_{n} * f$ to $f(x)=e^{-i n \arg (x)} \chi_{A}(x)$ where $A$ is the annulus $\{1 \leq|x| \leq 1+1 / n\}$. One observes that there is a constant $C$ such that $\left|T_{n} f(x)\right| \geq C$ if $|x| \leq C / n$ and (2) follows (for all $p$, but (1) is better for $p \leq 4$ ).

The example for (1) is a little more complicated: for fixed $n$, and $1 \leq j \leq n^{1 / 3}$, let $\theta_{j}=j n^{-1 / 3}, \omega_{j}=\left(\cos \left(\theta_{j}\right), \sin \left(\theta_{j}\right)\right)$, and $\omega_{j}^{\prime}=\left(-\sin \left(\theta_{j}\right), \cos \left(\theta_{j}\right)\right)$. Let $B_{j}$ be the disk $\left\{\left|x-\omega_{j}\right| \leq \varepsilon n^{-\frac{1}{3}}\right\}$ where $\varepsilon$ is a positive number independent of $n$ and small enough to insure that, for any $n$, the disks $B_{j}$ are pairwise disjoint. Let

$$
f_{j}(x)=e^{i n\left(x \cdot \omega_{j}^{\prime}\right)} \chi_{B_{j}}(x)
$$

One can check that

$$
\begin{equation*}
\left|T_{n} f_{j}(x)\right| \geq c n^{-\frac{1}{3}} \quad \text { if } \quad|x| \leq c n^{-\frac{1}{3}} \tag{5}
\end{equation*}
$$

for some small positive $c$ independent of $n$ and $j$. Let $r_{j}$ be the $j$ th Rademacher function on $[0,1]$ and put

$$
f(t, x)=\sum_{j=1}^{n^{\frac{1}{3}}} r_{j}(t) f_{j}(x)
$$

Then

$$
\begin{equation*}
\|f(t, \cdot)\|_{p} \leq C n^{-\frac{1}{3 p}} \tag{6}
\end{equation*}
$$

Also

$$
\int_{0}^{1}\left\|T_{n} f(t, \cdot)\right\|_{p}^{p} d t \geq \int_{|x| \leq c n^{-1 / 3}}\left(\sum_{j}\left|T_{n} f_{j}(x)\right|^{2}\right)^{p / 2} d x \geq c^{2+p} n^{-\frac{2}{3}-\frac{p}{6}}
$$

where the third inequality uses (5). With (6) this yields (1).
A computation shows that $\widehat{T}_{n}(\xi)=e^{i n \arg (\xi)} J_{n}(|\xi|)$ (whence the name of this note). Thus (3) follows from the estimate, uniform in $n$,

$$
\left|J_{n}(r)\right| \leq C r^{-\frac{1}{3}} \quad \text { if } \quad r \geq 1
$$

(see p. 357 in $[\mathrm{S}]$ ) combined with the observation

$$
\begin{equation*}
\left|J_{n}(r)\right| \leq \frac{C}{n} \quad \text { if } \quad 0 \leq r \leq \frac{3 n}{4} \tag{7}
\end{equation*}
$$

To begin the proof of (4), let $\rho$ be a smooth cutoff function which is equal to 1 on the annulus $\left\{\frac{3}{4} \leq|\xi| \leq \frac{5}{4}\right\}$ and is supported in the annulus $\left\{\frac{1}{2} \leq|\xi| \leq \frac{3}{2}\right\}$. Let $S_{n}$ be the operator defined by $\widehat{S}_{n}(\xi)=\widehat{T}_{n}(\xi) \rho\left(\left|n^{-1} \xi\right|\right)$. The easy estimate

$$
\left|J_{n}(r)\right| \leq C n^{-\frac{1}{2}} \quad \text { if } \quad r \geq \frac{5 n}{4}
$$

combines with (7) to show that the $L^{2}\left(\mathbb{R}^{2}\right)$ operator norm $\left\|T_{n}-S_{n}\right\|_{2,2}$ is $O\left(n^{-\frac{1}{2}}\right)$. Interpolating this with $\left\|T_{n}-S_{n}\right\|_{\infty, \infty}=O(1)$ yields $\left\|T_{n}-S_{n}\right\|_{4,4}=O\left(n^{-\frac{1}{4}}\right)$. Thus (4) will follow from

$$
\begin{equation*}
\left\|S_{n}\right\|_{4,4} \leq C n^{-\frac{1}{4}}(\log (n))^{a} \tag{8}
\end{equation*}
$$

which is our principal result. The Fourier transform $\widehat{S}_{n}(\xi)$ is supported in the annulus $A_{n}=\left\{\frac{n}{2} \leq|\xi| \leq \frac{3 n}{2}\right\}$. Having fixed $n$, we will decompose $S_{n}$ by decomposing $A_{n}$ into a union of annuli $A_{n}^{j}$ as follows:

$$
\begin{aligned}
\text { for } j \geq 1 \text {, set } A_{n}^{j} & =\left\{n+2^{j} n^{\frac{1}{3}} \leq|\xi| \leq n+2^{j+1} n^{\frac{1}{3}}\right\} \\
\text { set } A_{n}^{0} & =\left\{n-2 n^{\frac{1}{3}} \leq|\xi| \leq n+2 n^{\frac{1}{3}}\right\} \\
\text { for } j \leq-1 \text {, set } A_{n}^{j} & =\left\{n-2^{|j|+1} n^{\frac{1}{3}} \leq|\xi| \leq n-2^{|j|} n^{\frac{1}{3}}\right\} .
\end{aligned}
$$

Introducing a suitable partition of unity on the Fourier transform side leads to the decomposition

$$
S_{n}=\sum_{j} S_{n}^{j}
$$

For fixed $n$, the number of terms $S_{n}^{j}$ is $O(\log (n))$. Thus (8) will follow from

$$
\begin{equation*}
\left\|S_{n}^{j}\right\|_{4,4} \leq C n^{-\frac{1}{4}}(\log (n))^{b} \tag{9}
\end{equation*}
$$

for all $j$ and $n$ and some $b>0$. At this point we make a further decomposition of $A_{n}^{j}$ into sectors $A_{n}^{j l}$ of opening angle $\delta \doteq 2^{|j| / 2} n^{-\frac{1}{3}}$. This leads to a decomposition

$$
S_{n}^{j}=\sum_{l=1}^{\delta^{-1}} S_{n}^{j l}
$$

The function $\widehat{S}_{n}^{j l}$ is supported in a set $R^{j l}$ obtained from the intersection of the annulus $n+\frac{1}{2} n \delta^{2} \leq|\xi| \leq n+3 n \delta^{2}$ with a sector of angle $\delta$; thus, $R^{j l}$ is essentially a rectangle of dimensions $n \delta$ by $n \delta^{2}$, with major dimension $n \delta$ normal to the vector through the center of $R^{j l}$.

## Lemma.

$$
\left\|S_{n}^{j l}\right\|_{4,4} \leq C n^{-\frac{1}{4}} \delta^{\frac{1}{4}}
$$

Proof. We will obtain the lemma by interpolating the following estimates:

$$
\begin{align*}
\left\|S_{n}^{j l}\right\|_{2,2} & \leq C(n \delta)^{-\frac{1}{2}},  \tag{10}\\
\left\|S_{n}^{j l}\right\|_{\infty, \infty} & \leq C \delta
\end{align*}
$$

The first estimate in (10) is a bound on $J_{n}(r)$ over the annulus $A_{n}^{j}$. The desired estimates are well known, but we provide the simple argument here for completeness.

For $j=0$, the desired bounds follow from the uniform bound $\left|J_{n}(r)\right| \leq C n^{-\frac{1}{3}}$. For $j \neq 0$, it suffices to show that

$$
\left|\int_{0}^{\pi} e^{i n t-i n\left(1 \pm \delta^{2}\right) \sin t} d t\right| \leq C(n \delta)^{-\frac{1}{2}}
$$

where $C$ is uniform over $n \in \mathbb{Z}$ and $\delta^{2} \leq 1 / 2$.
We let $\phi(t)=t-\left(1 \pm \delta^{2}\right) \sin t$. On the interval $0 \leq t \leq \delta$, we have $\left|\phi^{\prime}(t)\right| \geq c \delta^{2}$, and $\phi^{\prime}(t)$ is monotonic, so Proposition 2 of [S], page 332, implies that

$$
\left|\int_{0}^{\delta} e^{i n t-i n\left(1 \pm \delta^{2}\right) \sin t} d t\right| \leq C\left(n \delta^{2}\right)^{-1} \leq C(n \delta)^{-\frac{1}{2}}
$$

On the interval $\delta \leq t \leq \pi-\delta$, it follows that $\left|\phi^{\prime \prime}(t)\right| \geq c \delta$, and the same proposition implies that

$$
\left|\int_{\delta}^{\pi-\delta} e^{i n t-i n\left(1 \pm \delta^{2}\right) \sin t} d t\right| \leq C(n \delta)^{-\frac{1}{2}}
$$

On the interval $\pi-\delta \leq t \leq \pi,\left|\phi^{\prime}(t)\right| \geq 1$, and the integral is bounded by $n^{-1}$.
For the second estimate of (10), it suffices to consider the term $S_{n}^{j 0}$, associated to the rectangle $R_{n}^{j 0}$ with center on the positive $\xi_{2}$ axis. The partition of unity element associated to this rectangle is of the form $\widehat{\psi}\left((n \delta)^{-1} \xi_{1},\left(n \delta^{2}\right)^{-1}\left(\xi_{2}-n\right)\right)$, where $\psi$ is a Schwartz function, whose seminorms are bounded by constants independent of $n, j, l$. Thus, the convolution kernel associated to $S_{n}^{j 0}$ is of the form

$$
K_{n}^{j 0}(x)=n^{2} \delta^{3} \int_{-\pi}^{\pi} e^{i n\left(x_{2}-\sin t\right)+i n t} \psi\left(n \delta\left(x_{1}-\cos t\right), n \delta^{2}\left(x_{2}-\sin t\right)\right) d t
$$

We need to show that

$$
\begin{equation*}
\int\left|K_{n}^{j 0}(x)\right| d x \leq C \delta \tag{11}
\end{equation*}
$$

The contribution from the integral over $|t| \leq \delta$ trivially satisfies (11), so it suffices to consider the following term:

$$
\widetilde{K}(x)=n^{2} \delta^{3} \int e^{i n(t-\sin t)} \chi\left(\delta^{-1} t\right) \psi\left(n \delta\left(x_{1}-\cos t\right), n \delta^{2}\left(x_{2}-\sin t\right)\right) d t
$$

where $\chi(s)=1$ for $|s| \geq 2$, and $\chi(s)=0$ for $|s| \leq 1$. Integration by parts yields

$$
\widetilde{K}(x)=i n \delta^{3} \int e^{i n(t-\sin t)} \frac{\partial}{\partial t}\left[\frac{\chi\left(\delta^{-1} t\right)}{1-\cos t} \psi\left(n \delta\left(x_{1}-\cos t\right), n \delta^{2}\left(x_{2}-\sin t\right)\right)\right] d t
$$

The term where the derivative falls on the term in front of $\psi$ satisfies (11), since

$$
\int\left|\frac{\partial}{\partial t}\left(\frac{\chi\left(\delta^{-1} t\right)}{1-\cos t}\right)\right| d t \leq C \delta^{-2} \leq C n \delta
$$

The term where the derivative falls on the $x_{2}$ place of $\psi$ also satisfies (11), since

$$
\int\left|\frac{\chi\left(\delta^{-1} t\right) \cos t}{1-\cos t}\right| d t \leq C \delta^{-1}
$$

The term where the derivative falls on the $x_{1}$ place of $\psi$ would appear to lead to bounds comparable to $\delta \log \left(\delta^{-1}\right)$; however, one further integration by parts shows that this term too satisfies (11).

We now prove (9) by noting that the angle $\delta$ was chosen so that the sets $R^{j l}+R^{j l^{\prime}}$ have bounded overlap for $R^{j l}$ and $R^{j l^{\prime}}$ in the same quadrant, i.e., so that the orthogonality argument of [F] applies. This argument yields

$$
\left\|\sum_{l} S_{n}^{j l} f\right\|_{4} \leq C\left\|\left(\sum_{l}\left|S_{n}^{j l} f\right|^{2}\right)^{\frac{1}{2}}\right\|_{4}
$$

The number of indices $l$ is $O\left(\delta^{-1}\right)$, so

$$
\sum_{l}\left|S_{n}^{j l} f(x)\right|^{2} \leq C \delta^{-\frac{1}{2}}\left(\sum_{l}\left|S_{n}^{j l} f(x)\right|^{4}\right)^{\frac{1}{2}}
$$

With $\widehat{f}_{j l}$ representing the localisation of $\widehat{f}$ to an appropriate sector, we thus have

$$
\begin{aligned}
\left\|\sum_{l} S_{n}^{j l} f\right\|_{4} & \leq C \delta^{-\frac{1}{4}}\left\|\left(\sum_{l}\left|S_{n}^{j l} f\right|^{4}\right)^{\frac{1}{4}}\right\|_{4} \\
& \leq C n^{-\frac{1}{4}}\left\|\left(\sum_{l}\left|f_{j l}\right|^{4}\right)^{\frac{1}{4}}\right\|_{4} \\
& \leq C n^{-\frac{1}{4}}\left\|\left(\sum_{l}\left|f_{j l}\right|^{2}\right)^{\frac{1}{2}}\right\|_{4}
\end{aligned}
$$

A result of Córdoba [C] gives

$$
\left\|\left(\sum_{l}\left|f_{j l}\right|^{2}\right)^{\frac{1}{2}}\right\|_{4} \leq C(\log (n))^{b}\|f\|_{4}
$$

for some positive $b$, which completes the proof of (9).
