47 **Abstract**

48 **Purpose:** To investigate the effects of combined sleep hygiene
49 recommendations and mindfulness on actigraphy-based sleep
50 parameters, perceptual wellbeing, anxiety and match outcomes
51 during high-performance junior tennis tournaments. **Methods:**
52 In a randomized crossover design, 17 high-performance junior
53 tennis players completed baseline, control and intervention
54 conditions across three separate weeks. Baseline consisted of
55 unassisted, habitual sleep during a regular training week and
56 control was unassisted sleep during a tournament week. Players
57 attended a sleep education workshop and completed a nightly
58 sleep hygiene protocol during a tournament week for the
59 intervention. Analysis was performed on weekly means and on
60 the night prior to the first match of the tournament (T-1).
61 **Results:** Significant differences were observed for increased
62 time in bed, total sleep time and an earlier bedtime ($P < 0.05$)
63 across the intervention week. These parameters also
64 significantly improved on T-1 of the intervention. A moderate
65 effect size ($P > 0.05$, $d > 1.00$) was evident for decreased worry on
66 T-1 of the intervention. Small effect sizes were also evident for
67 improved mood, cognitive anxiety and sleep rating were evident
68 across the intervention week. Match performance outcomes
69 remained unchanged ($P > 0.05$). **Conclusions:** Sleep hygiene
70 interventions increase the sleep duration of high-performance
71 junior tennis players in tournament settings, including the night
72 prior to the tournament's first match. Effects on perceptual
73 wellbeing and anxiety are unclear, though small trends suggest
74 improved mood, despite no effect on generic match performance
75 outcomes.

78 anxiety

79 **Introduction**

80 Sleep is considered important for optimal athletic preparation
81 and post-exercise recovery. However, evidence suggests that
82 athletes experience poor sleep quantity and quality¹, particularly
83 individual¹ and junior athletes² and on nights preceding
84 important competitions^{3,4}. In turn, high-level junior (14-18-
85 years) tennis players are exposed to condensed training
86 schedules and tournament fixtures, which requires a considered
87 approach to preparation and recovery⁵. Accordingly, high-level
88 junior tennis players encompass these at-risk cohorts and
89 situations, and strategies to alleviate truncated sleep behaviour
90 are of interest to practitioners and researchers.

91
92 Susceptibility to poor sleep quantity and quality is often
93 attributed to the contextual challenges faced as being both an
94 adolescent (period characterised by an array of psychological
95 and physical changes, including a natural phase delay in
96 circadian timing leading to later bedtimes) and an athlete (e.g.
97 competition stress and anxiety)⁶. Of importance are the effects a
98 tournament may have on players' sleep. High-level junior tennis
99 tournaments have congested schedules resulting in players
100 competing in up to three matches per day with heightened
101 physical and cognitive demands⁷, which may degrade sleep
102 quantity and quality⁸. Furthermore, with a majority of
103 tournaments being played away from home and athletes staying
104 in unfamiliar environments, there is greater risk for poor sleep
105 quality⁸. Further, the psychological and emotional toll of a
106 competitive match is elevated in comparison to training, with
107 greater somatic and cognitive anxiety states present on the nights
108 prior to competition⁹. Moreover, tennis players' emotions can
109 vary, dependent on the outcomes of their matches⁶, thus
110 tournaments with multiple matches will greatly impact ones
111 stress and anxiety, typified by emotional outbursts becoming
112 more prominent as tournaments progress¹⁰. However, if an
113 athlete is able to achieve adequate sleep, they may be more likely
114 to improve the regulation and response to stress¹¹. Since
115 heightened stress can reduce sleep duration¹², approaches to
116 improve the sleep of junior tennis players in tournament settings
117 are warranted.

118
119 Due to the simplicity of implementation and the lack of
120 resources required¹³, sleep hygiene (SH) may be an appropriate
121 strategy for junior athletes to enhance their sleep during
122 competition. SH interventions are typified by education and
123 modification of night-time behaviours to improve sleep quantity
124 and quality^{13,14}. Commonly used protocols include restricted
125 exposure to light and technology prior to sleeping and
126 manipulation of the sleep environment (temperature and noise)
127 ¹³. In addition, mindfulness has been used to enhance relaxation
128 states¹⁵ and improve sleep onset latency¹⁶. Despite the present

129 benefits of SH to general populations¹⁷, the effect of these
130 interventions in athletes is mixed. For instance, in acute settings,
131 football players have shown to obtain over 1.5 h more sleep after
132 a late-night match compared to controls; however, the
133 restoration of physical performance was unchanged¹⁸.
134 Comparatively, extended sleep (2 h) has shown to significantly
135 improve sprint performance of basketball players¹⁹ and serving
136 accuracy of tennis players²⁰. Ongoing sleep education may be
137 beneficial as it has shown to have psychological benefits such as
138 increased subjective performance, sleep quality²¹, perceived
139 fatigue and vigour²². Collectively, although SH education shows
140 acute benefits (i.e. increased sleep duration) for adult athletic
141 populations^{14,23}, the conflicting evidence of its effect on
142 performance, wellbeing and anxiety requires further
143 investigation, particularly in junior athletes. Therefore, the aim
144 of this study was to investigate the effects of a week-long
145 combined SH and mindfulness intervention during competitive
146 tournaments on objective measures of sleep, perceptual
147 wellbeing and performance in high-performance junior tennis
148 players.

149

150 **Methods**

151 *Subjects*

152 Seventeen high-level junior tennis players (male n=10, female
153 n=7; age=15.4 ± 1.1; height=171.5 ± 11.2 cm; mass=60.7 ± 10.2
154 kg) participated in the study. The players were Tennis Australia
155 (TA) scholarship athletes (Australian ranking, male=218 ± 119;
156 female=205 ± 129) from two state-based National Academies
157 (Sydney and Adelaide). All players and parents/guardians were
158 provided with detailed information about the study. All available
159 scholarship athletes were invited to volunteer, however inclusion
160 criteria required athletes to participate in at least two tournament
161 weeks and a baseline week within the study timeframe. Players
162 were not screened for sleep disorders, but none had reported
163 sleep-related issues from TA medical staff in the preceding six
164 months. If players were eligible for the study timeframe, and
165 wished to volunteer, informed consent was obtained from both
166 parents and the participants, and ethical approval from the
167 institutional ethics committee was granted (ETH19-3391).

168

169 *Design*

170 Two groups completed baseline (BASE), control (CON) and
171 intervention (INT) conditions in a randomised crossover design
172 (Figure 1). BASE observation was within the home environment
173 during a regular training week (4-5 training days per week, 2-3
174 sessions per day, typically between 08:00–09:30 and 15:00–
175 19:00) whilst CON (unassisted, normative sleep behaviour) and
176 INT were during two separate tournament weeks. INT consisted
177 of a “sleep education” workshop prior to the tournament, and a
178 nightly SH and mindfulness routine implemented within one of

179 the tournament weeks. The tournaments were of Junior ITF (G4-
180 G5) level played on hardcourt over six days between April and
181 September 2019. Objective sleep parameters were collected with
182 wristwatch actigraphy and combined with subjective sleep
183 diaries each night within each seven-day period. Perceptual
184 wellbeing questionnaire responses were collected upon
185 awakening each morning and the Competitive State Anxiety
186 Inventory-2 (CSAI2²⁴) was completed on night 1 of BASE and
187 the night prior to the tournament (T-1), as well as night two and
188 five throughout CON and INT. The Athlete Sleep Screening
189 Questionnaire (ASSQ²⁵) was completed on night one of each
190 condition and the reduced-Morningness-Eveningness
191 questionnaire (rMEQ²⁶) was completed on night one of BASE
192 only. These three questionnaires are typically used to provide a
193 snapshot (i.e. weekly) of the players' condition as opposed to
194 daily use. Tournament match results were recorded during CON
195 and INT.

196 (Insert Figure 1 near here)

197

198 **Methodology**

199 Tri-axial accelerometer actigraphy devices (Actigraph wGT3x-
200 BT, ActiGraph Corporation, Pensacola, FL, USA) were set for
201 players' height, body mass, date of birth and non-dominant wrist
202 to provide estimates of sleep quantity and quality and worn from
203 30 min prior to going to bed until waking. Actigraphy monitors
204 have shown acceptable agreement rates (81-91%) to
205 polysomnography (PSG) in elite adult athletes and are deemed a
206 valid method to monitor sleep in athletic populations^{27,28}. In
207 addition, actigraphy holds advantages in youth populations due
208 to their cost effective and non-intrusive nature^{27,28}. Devices were
209 set at a sampling frequency of 60Hz with a 60s epoch²⁷.
210 Following each week of monitoring, data was downloaded using
211 the manufacturer's proprietary software (Actilife, Actigraph
212 Corporation, Pensacola, FL, USA). With the assistance of a
213 subjective diary, bedtimes (BT) and waketimes (WT) were
214 entered into the sleep analysis section of the software using the
215 Sadeh algorithm²⁹. Weekly averages for sleep parameters as well
216 as values of the night prior to the first match of the tournament
217 (T-1) were analysed due to evidence that sleep quantity and
218 quality can be truncated prior to important competitions³. In
219 addition, as tournament weeks vary dependent on player results,
220 T-1 represents a standardized pre-first match night.

221

222 Player wellbeing data was obtained from the TA database
223 (Athlete Management System) for which players answered a
224 daily questionnaire (immediately upon waking) on a mobile
225 application using VAS scales between 1-10. Subjective sleep
226 quality was assessed using a VAS scale, with (1 =very bad/very
227 restless – 10 =no disturbances) as part of TA athlete monitoring.
228 The CSAI2 was used to assess feelings of anxiety and

229 confidence. The CSAI2 has been shown to be a valid and reliable
230 measure of cognitive and somatic anxiety as well as self-
231 confidence among a broad range of athletes (i.e. age, gender,
232 sport), yet provided the length (27 questions) of it, is suggested
233 not to be utilised daily²⁴. Furthermore, the ASSQ was used to
234 determine the level of difficulty athletes have in achieving sleep,
235 for which the scoring system shows good agreement (81% for
236 moderate-severe; 93% for none-mild) with sleep medicine
237 physicians diagnosis²⁵. Participants who were categorised as
238 'severe' in the ASSQ aligned with physician recommendations
239 of requiring follow-up treatment²⁵. The rMEQ, which provides
240 an accurate prediction of chronology preferences in the general
241 population ²⁶, was used for descriptive purpose.

242
243 Match data, including duration, and results (i.e. games won, and
244 games lost) were collated during each tournament from
245 tournament organisers, while athletes provided a subjective
246 rating of their performance on a VAS (1 =very poor – 10 =best
247 you've played) scale following each match. Previous research
248 suggests that sleep extension²⁰ and sleep restriction³⁰ may effect
249 tennis-specific performance, though stroke or matchplay level
250 analyses were not available.

251
252 Athletes were given no instruction as to how they should sleep
253 while they were based in their home environment during a
254 regular training week (BASE). Players completed the CSAI-2,
255 ASSQ and rMEQ questionnaires once only on night one.
256 Athletes were given no instruction as to how they should sleep
257 during the tournament (CON). The CSAI-2 was completed on T-
258 1 and nights two and five of the tournament. ASSQ was
259 completed once only on T-1. Match results were collected daily.

260
261 Players were presented with a "sleep education" workshop
262 (approx. 40 min) by the lead investigator three days prior to the
263 tournament (INT). This presentation highlighted evidence of
264 poor sleep in athletic populations, potential causes of poor
265 sleeping and the ensuing effects (positive and negative) on
266 performance (athletic, academic and general health), examples
267 of high-profile athletes who support the importance of sleep and
268 a SH routine to improve their bedtime habits. Following this
269 presentation in the days leading up to the tournament, players'
270 familiarised themselves with the SH protocol. Players were then
271 instructed to follow the SH protocol information package each
272 night throughout the tournament. The SH protocol consisted of
273 the following; no consumption of caffeine or other stimulants
274 after 15:00, at 20:00, a reminder was sent to the group to prepare
275 their bedroom (cool – 18-21°C or as comfortable; dark –
276 blinds/curtains drawn; and quiet – remove any noisy objects if
277 possible) and start thinking about commencing the 'power-
278 down' hour; by 20:30 athletes were to have commenced their

279 'power-down' hour (reduce exposure to light, limit use of
280 technology and minimise physical activity). Athletes were
281 instructed to be in bed by 21:30 with their actigraphy watch on.
282 Once in bed athletes were instructed to start listening to a
283 mindfulness recording focusing on breathing and body
284 awareness (12 min) with their eye mask on. The recording (Body
285 Scan for Sleep: Saturating the Body with the Breathe,
286 Breathworks CIC, Manchester, United Kingdom), used nightly,
287 has been previously shown to improve sleep onset latency of
288 adolescents when used immediately prior to sleep¹⁶. Finally, by
289 21:45 (or immediately after, if not during, the recording) athletes
290 were instructed to attempt to fall asleep.

291

292 The CSAI-2 was completed on T-1 and nights two and five of
293 the tournament. ASSQ was completed once only on T-1. Match
294 results were collected daily. Communication with athletes was
295 through an instant messaging application (WhatsApp,
296 WhatsApp Inc., Mountain View, California, United States))
297 which allows the sender to see who has viewed the
298 message/attachment and when they viewed it. This was
299 monitored each night by researchers in conjunction with parents,
300 along with a nightly checklist to ensure adherence to the
301 protocol. All participants completed the checklists and adhered
302 to the protocol.

303

304 *Statistical Analysis*

305 Descriptive statistics are presented for all variables as mean \pm
306 SD. A repeated measure analysis of variance (ANOVA) was
307 performed to determine differences in sleep parameters,
308 wellbeing and performance between conditions (BAS, CON and
309 INT). Greenhouse-Geisser corrections were applied where
310 significance was observed in Mauchly's Test of Sphericity.
311 Pairwise comparisons were used to locate differences where
312 main effects were evident. Significance was set at $P < 0.05$.
313 Statistical analysis was performed in Statistical Package for the
314 Social Sciences (IBM SPSS Statistics for Macintosh, Version
315 25.0. Armonk, NY). In addition, effect sizes (ES) (Cohen's D,
316 95% confidence intervals) were calculated on a customised
317 Microsoft Excel spreadsheet (Microsoft, Redmond, USA)³¹ to
318 determine the magnitude of effect of the conditions. ES were
319 interpreted as < 0.2 , trivial; 0.2-0.6, small; 0.6 – 1.2, moderate;
320 1.2 – 2.0, large; > 2.0 , very large³¹.

321

322 **Results**

323 *Objective sleep parameters*

324 All mean weekly sleep parameters for BASE, CON and INT are
325 presented in Table 1. A significant increase in TBT was evident
326 for INT compared to BASE ($P = 0.02$, $d = 0.74$) and CON ($P < 0.01$,
327 $d = 0.98$), along with significant increases in TST for INT
328 compared to both BASE ($P < 0.01$, $d = 0.68$) and CON ($P < 0.01$,

329 d=0.90). Small ES were observed for a shorter TIB (P=1.00, d=-
330 0.24) and TST (P=1.00, d=-0.22) for CON compared to BASE.
331 BT was significantly earlier during INT than both BASE
332 (P<0.01, d=-0.75) and CON (P<0.01, d=-0.69). Small and
333 moderate ES were evident for shorter SOL in INT compared to
334 CON (P=1.00, d=-0.37) and BASE (P=0.24, d=-0.66). The
335 remaining sleep parameters (WT, SE, WASO, WE and WED)
336 were not significantly different (P>0.05) with trivial or small ES
337 (d=0.10-0.60) between conditions.

338 (Insert table 1 near here)

339

340 Table 2 shows the sleep parameters on the night prior to the
341 beginning of each tournament. A significant difference and
342 moderate ES existed for increased TST (+0.72 ± 0.78 h) for INT
343 T-1 to CON T-1 (P=0.01, d=0.98). BT for INT T-1 was
344 significantly earlier than CON T-1 (P<0.01, d=-0.88). TIB was
345 significantly longer and had a large ES for INT T-1 (P=0.01,
346 d=1.66), with athletes achieving 1.03 ± 0.82 h additional time in
347 bed compared to CON T-1.

348 (Insert table 2 near here)

349

350 ***Perceptual wellbeing***

351 Perceptual wellbeing measures for all conditions are presented
352 in Table 3. There was a significant difference and moderate ES
353 (P<0.01, d=-0.72) for increased feelings of worry in CON
354 compared to BASE, with a similar ES (P=0.30, d=-0.76) for INT
355 to BASE. A significant difference was observed for lower levels
356 of confidence in CON compared to BASE (P=0.03, d=-0.65),
357 along with a small ES (P=1.00, d=-0.50) for INT respectively. In
358 addition, cognitive anxiety levels in CON moderately increased
359 from BASE (P=1.00, d=0.51) and showed a small decrease in
360 INT from CON (P=1.00, d=-0.21). Sleep rating demonstrated
361 small ES for an increase from BASE (P=0.95, d=0.32) and CON
362 (P=0.51, d=0.25) to INT. ASSQ responses across BASE, CON
363 and INT all scored in the 'severe' category for difficulty in
364 sleeping and did not differ (P>0.05) between conditions. Mean
365 rMEQ scores were 16.88 ± 3.43, classifying the group as a
366 neutral chronotype. Remaining wellbeing measures (fatigue,
367 mood, hunger and somatic anxiety) showed no significant
368 differences (P>0.05), with trivial (d<0.20) or small (d=0.20-
369 0.60) ES between conditions.

370 (Insert table 3 near here)

371

372 Wellbeing measures prior to the beginning of the tournament are
373 presented in Table 4. No significant differences (P>0.05) and
374 small-trivial ES were observed between conditions. However, a
375 moderate ES (P=0.20, d=1.01) was evident for a decrease in
376 feelings of worry for INT T-1 compared to CON T-1.

377 (Insert table 4 near here)

378

379

380 **Performance**

381 Table 5 shows the performance measures recorded during CON
382 and INT tournament conditions. No significant differences were
383 observed ($P>0.05$), with small ES observed for an increase in the
384 amount of games lost ($P=1.00$, $d=-0.29$), decrease in subjective
385 performance ($P=1.00$, $d=0.36$) and an increase in match duration
386 ($P=1.00$, $d=-0.30$) in INT compared to CON. No significant
387 differences ($P>0.05$) were observed for performance measures
388 between conditions for the first main draw match (M1) of each
389 tournament in INT and CON. Small ES ($d=0.20-0.60$) for match
390 duration and trivial ($d<0.20$) ES for games won, games lost and
391 player rating were evident.

392 (Insert table 5 near here)

393

394 **Discussion**

395 This study shows that a combined SH and mindfulness
396 intervention can improve sleep quantity in high-performance
397 junior tennis players during tournaments, particularly on the
398 night before a tournament/first match. Specifically, a single
399 sleep education workshop and nightly routine led to significant
400 improvements in weekly objective actigraphy parameters (TIB,
401 TST and BT), as well as the night preceding the tournament. In
402 addition, there were small-moderate effects for decreased
403 feelings of worry and increased confidence in the SH condition
404 compared to CON on the night preceding the tournament.
405 Despite no changes to general match outcome characteristics, the
406 present findings suggest that acute SH and mindfulness is
407 effective to improve sleep and potentially perceptual wellbeing
408 and anxiety in tournament settings.

409

410 The primary finding of our study was that SH and mindfulness
411 practices increased sleep duration during a week-long
412 tournament. Similar weekly increases in sleep duration
413 following SH education have been previously shown for elite
414 netballers (+22 min)¹⁴ and rugby league players (+20 min)²³ and
415 highlights sleep education and hygiene can effectively adjust
416 acute sleep behaviour in athletic populations. Sleep as a recovery
417 strategy is of particular importance during a tournament when
418 athletes are required to elicit daily physical and cognitive
419 demands, as well as constantly increase arousal levels and often
420 be aggressive in their technical play⁶. By creating a conducive
421 environment for sleep (e.g. limiting light exposure) and
422 adjusting night-time behaviours (e.g. mindfulness and
423 preparedness for sleep)¹³, the transition to a physical and
424 cognitive homeostasis may be better achieved. It should also be
425 noted the mean sleep durations in each condition were still lower
426 than recommended for adolescents². Since the present study has
427 shown SH to improve sleep in tournament settings, combined
428 with the fact that high-performing junior tennis players compete

429 in 18-25 tournaments or 125-150 matches per year^{5,9}, the
430 implementation of sleep education and protocols is
431 recommended for these players' during tournament routines.

432

433 Similar to the findings of increased sleep over the week, there
434 were significant improvements in TIB, TST and BT on the night
435 preceding the first match while using SH. These results concur
436 with Fullagar, Skorski, Duffield, Meyer¹⁸, who found
437 comparable results (+99 min) following the use of an acute SH
438 protocol with highly-trained soccer players after a late-night
439 match. Additionally, tennis players have been shown to be able
440 to achieve 60 min additional sleep time on a single night
441 following repeated on-court training when utilising a SH
442 protocol³². The initial benefit to sleep duration in our study, as
443 well as previous research, may be attributed to the correction of
444 poor in-tournament SH behaviours as indicated by the ASSQ
445 scores. Since sleep quantity and quality is generally poorer on
446 the night prior to a competition³, the findings in our study
447 suggest that acute SH and mindfulness may offer a practical
448 solution to alleviating the acute risks to sleep duration that come
449 on the night before a tournament commences.

450

451 Interestingly, the improved sleep quantity in our study was
452 accompanied by moderate decreases in worry on the morning of
453 the first match. Gymnasts have previously displayed comparable
454 results prior to competition where greater sleep quality was
455 associated with lower levels of precompetitive stress¹¹.
456 However, it should be acknowledged that the improvements
457 noted in our study were smaller than that of Silva, Paiva¹¹;
458 potentially given sleep efficiency and subjective sleep quality
459 remained unchanged, thus sleep quality may be a stronger
460 determinant of mood than sleep duration¹³. Nonetheless, any
461 advantage in reducing stress prior to a tournament should be
462 explored further, such as the inclusion of additional mindfulness
463 and meditation education and practice which has shown initial
464 benefit for adolescents with sleep problems and anxiety¹⁶.

465

466 Increased feelings of worry and decreased self-confidence in
467 addition to a moderate increase in cognitive anxiety in
468 tournament settings compared to baseline were observed. This
469 concurs with previous research suggesting tournaments elicit
470 increased feelings of anxiety and worry³³. Indeed, individual
471 athletes commonly report nervousness and anxiety prior to
472 competition as the key reason for poor and disrupted sleep^{3,4}.
473 Interestingly, despite the continual protocol throughout the
474 week, our study only observed small and trivial improvements
475 in perceptual wellbeing. Reasons for the lack of an effect on
476 perceptual measures may have been due to participants losing at
477 some point during the week, resulting in less pressure and
478 competitive anxiety for the remainder of the week when

479 competing in consolation matches. Given that emotions are
480 linked with match performance and outcomes in junior tennis
481 players⁶, collectively, this suggests that tournament results may
482 have a greater impact on wellbeing than sleep.

483
484 No significant differences were observed for generic match
485 outcomes in the present study. These results concur with
486 previous research, with Fullagar, Skorski, Duffield, Meyer¹⁸
487 reporting no improvement in jump or intermittent running
488 performance, blood-based variables nor psychological recovery
489 among soccer players despite improved sleep duration. In
490 contrast, there is evidence that longer TST (i.e. sleep extension)
491 may improve physical and cognitive performance¹³. For
492 instance, sleep extension protocols resulted in improved serving
493 accuracy for tennis players²⁰, significantly greater physical,
494 cognitive and sport-specific performance among college
495 basketball players¹⁹ and reaction time of rugby players³⁴.
496 Despite this promising initial evidence, these studies were set in
497 controlled training environments, and as such lack ecological
498 validity to tournaments. Indeed, tournament settings are vastly
499 different and thus performance may be predominantly affected
500 by other factors unique to competition. Future research may
501 focus on associations with sleep behaviour and more granular
502 movement, technical and tactical measures within tennis.

503
504 Provided this was a field-based study, there are limitations that
505 must be acknowledged. The study had a limited sample size due
506 to the already constrained population (i.e. high-performance
507 junior tennis players) and selection of players that met the
508 inclusion criteria (i.e. playing at particular tournaments).
509 Actigraphy was used in place of PSG to monitor sleep as it's a
510 non-invasive and portable device. Given the use of two strategies
511 within our study (i.e. mindfulness to compliment SH), it is
512 difficult to discern if either particular method had a greater effect
513 on the outcome measures. With tournaments occurring away
514 from home, as usual, players/parents were required to organise
515 their own accommodation (e.g. hotels), resulting in non-
516 standardised sleep environments which may impact how the
517 intervention was implemented. However, this limitation also
518 leads to ecological validity of such an intervention being able to
519 be implemented in real scenarios. Furthermore, specific
520 enforcement of the intervention (i.e. researchers/staff checking
521 bedrooms) was deemed unacceptable given the age of the
522 players (under 18). The performance measures used in the study
523 may not have been as susceptible to changes in sleep compared
524 to serve accuracy or groundstroke errors, however these metrics
525 were not available. Furthermore, match load and the time of day
526 matches took place were unable to be controlled given it was an
527 official tournament setting. Finally, due to the nature of the

528 intervention, blinding of participants and assessors was not
529 possible.

530

531 **Practical Applications**

532 The findings of this study can be applied in the field by coaching
533 and performance staff within tennis academies to benefit high-
534 performance junior players:

535 • SH education, protocols and mindfulness increase the
536 sleep duration of high-performance junior tennis players,
537 thus may be used during tournaments to improve sleep
538 behaviour.

539 • Coaches and players should, in particular, consider such
540 protocols prior to the first match, when anxiety and stress
541 are typically greater, to alleviate feelings of worry and
542 anxiety and increase self-confidence.

543 • The education session may be utilised to promote
544 positive sleep behaviours and healthy bedtime routines.

545

546 **Conclusion**

547 The current investigation is the first to show that a combined SH
548 and mindfulness intervention including a single education
549 session and nightly protocol can have a positive effect on
550 actigraphy based sleep indices and perceptual wellbeing,
551 including anxiety during a tournament. Furthermore, the
552 intervention was of particular benefit on the night preceding the
553 tournament in potentially alleviating feelings of worry and
554 increasing sleep duration. Future research should look to
555 investigate effects on tennis-specific performance outcomes
556 (e.g. serve accuracy and groundstroke errors) during the
557 tournaments when utilising such protocols, whilst also looking
558 to obtain participant feedback. In addition, a chronic approach
559 with long term follow ups to SH among junior athletes should be
560 explored, to assess whether ongoing education is more
561 beneficial.

562

563 **Acknowledgements**

564 Tennis Australia provided funding for equipment (eye masks)
565 which contributed to the development of this manuscript. The
566 authors report no conflicts of interest. The authors sincerely
567 appreciate the time and participation given by the players. The
568 coaches and performance staff must also be thanked for their
569 assistance and support of the project.
