#### Abstract

Although methanol synthesis via CO hydrogenation has been industrialized, $\mathrm{CO}_{2}$ hydrogenation to methanol still confronts great obstacles of low methanol selectivity and poor stability, particularly for supported metal catalysts under industrial conditions. We report a binary metal oxide, $\mathrm{ZnO}^{2} \mathrm{ZrO}_{2}$ solid solution catalyst, which can achieve methanol selectivity of up to 86 to $91 \%$ with $\mathrm{CO}_{2}$ single-pass conversion of more than $10 \%$ under reaction conditions of $5.0 \mathrm{MPa}, 24,000 \mathrm{ml} /\left(\mathrm{g}\right.$ hour), $\mathrm{H}_{2} / \mathrm{CO}_{2}=3: 1$ to $4: 1,320^{\circ}$ to $315^{\circ} \mathrm{C}$. Experimental and theoretical results indicate that the synergetic effect between Zn and Zr sites results in the excellent performance. The $\mathrm{ZnO}^{2} \mathrm{ZrO}_{2}$ solid solution catalyst shows high stability for at least 500 hours on stream and is also resistant to sintering at higher temperatures. Moreover, no deactivation is observed in the presence of $50 \mathrm{ppm} \mathrm{SO} \mathrm{SO}_{2}$ or $\mathrm{H}_{2} \mathrm{~S}$ in the reaction stream.

## INTRODUCTION

Global environmental changes caused by huge amounts of anthropogenic $\mathrm{CO}_{2}$ emissions have become a worldwide concern. However, $\mathrm{CO}_{2}$ is an abundant and sustainable carbon resource. It is highly desired to develop technologies to convert $\mathrm{CO}_{2}$ into valuable chemicals. Among the strategies considered, catalytic hydrogenation of $\mathrm{CO}_{2}$ to methanol using the hydrogen from renewable energy sources has received much attention, because methanol not only is an excellent fuel but also can be transformed to olefins and other high value-added chemicals commonly obtained from fossil fuels (1).

Much progress has been made in the development of supported metal catalysts for $\mathrm{CO}_{2}$ hydrogenation, such as $\mathrm{Cu} / \mathrm{ZnO} / \mathrm{Al}_{2} \mathrm{O}_{3}(2-10), \mathrm{Cu} / \mathrm{ZrO}_{2}$ (2-5, 11-13), and $\mathrm{Pd} / \mathrm{ZnO}(2-5,14,15)$. Among these, the $\mathrm{Cu} / \mathrm{ZnO} / \mathrm{Al}_{2} \mathrm{O}_{3}$ catalyst was the most efficient and has been extensively studied. However, one of the problems for these catalysts is the low methanol selectivity caused by reverse water-gas shift (RWGS) reaction. The even more severe problem is the rapid deactivation caused by produced water, which accelerates the sintering of Cu active component during the $\mathrm{CO}_{2}$ hydrogenation (16). Although more efficient "georgeite" Cu -based catalyst (17), $\mathrm{Cu}(\mathrm{Au}) / \mathrm{CeO}_{x} / \mathrm{TiO}_{2}(18,19)$, and $\mathrm{Ni}(\mathrm{Pd})-\mathrm{Ga}(20-22)$ catalysts have been reported, the selectivity toward methanol is lower than $60 \%$ under their reported conditions. Recently, higher methanol selectivity is reported for $\mathrm{In}_{2} \mathrm{O}_{3}(23-25)$. However, this is compromised by low $\mathrm{CO}_{2}$ conversion (25). Up to now, we are still lacking an efficient catalyst that enables a $\mathrm{CO}_{2}$ hydrogenation conversion above $10 \%$ with high methanol selectivity and stability to fulfill the requirements of large-scale production under industrial operation conditions. Here, we report a $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution catalyst, which shows methanol selectivity of 86 to $91 \%$ at a $\mathrm{CO}_{2}$ conversion of more than $10 \%$ under the conditions of $5.0 \mathrm{MPa}, 24,000 \mathrm{ml} /\left(\mathrm{g}\right.$ hour), $\mathrm{H}_{2} / \mathrm{CO}_{2}=3: 1$ to $4: 1,320^{\circ}$ to $315^{\circ} \mathrm{C}$, demonstrated with a fixed-bed reactor. The catalyst shows excellent stability for more than 500 hours on stream, and it is promising for the conversion of $\mathrm{CO}_{2}$ to methanol in industry.

## RESULTS AND DISCUSSION

A series of $x \% \mathrm{ZnO}_{-2 \mathrm{ZrO}}^{2}$ catalysts ( $x \%$ represents molar percentage of Zn , metal base) were prepared by the coprecipitation method, and their catalytic performances were investigated as shown in Fig . 1. $\mathrm{ZrO}_{2}$ shows very low activity in methanol synthesis. ZnO shows a little activity and low methanol selectivity (table S1). However, the performance of the $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst varies greatly with the $\mathrm{Zn} /(\mathrm{Zn}+\mathrm{Zr})$ molar ratio (Fig. 1A). The catalytic activity is significantly enhanced and reaches the maximum for $\mathrm{CO}_{2}$ conversion when the $\mathrm{Zn} /(\mathrm{Zn}+\mathrm{Zr})$ molar ratio is close to $13 \%$. This is also where the methanol selectivity (mainly methanol and CO as the products) is approaching the maximum (fig. S1). Therefore, the highest space-time yield (STY) of methanol is achieved for the $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst at the $\mathrm{Zn} /(\mathrm{Zn}+\mathrm{Zr})$ molar ratio of $13 \%$, and hereafter, it represents the optimized catalyst. It is worth noting that the $\mathrm{CO}_{2}$ conversion of $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ is about 1.3 and 14 times of those for ZnO and $\mathrm{ZrO}_{2}$, respectively, and the methanol selectivity is increased from no more than $30 \%$ for ZnO or $\mathrm{ZrO}_{2}$ to more than $80 \%$ for $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$. More interestingly, the activity of $13 \%$ $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ is about six times of that for mechanically mixed ZnO and $\mathrm{ZrO}_{2}$ in the same composition as $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ (inset in Fig. 1A), indicating that there is a strong synergetic effect between these two components in the catalytic activity of $\mathrm{CO}_{2}$ hydrogenation.

Figure 1 B shows that when increasing the reaction temperature, the selectivity of methanol decreases, whereas the conversion of $\mathrm{CO}_{2}$ increases. When the conversion reaches $10 \%$ at $320^{\circ} \mathrm{C}$, the selectivity of methanol can still be kept at $86 \%$. Higher pressure, gas hourly space velocity (GHSV), and $\mathrm{H}_{2} / \mathrm{CO}_{2}$ ratio are beneficial to the methanol selectivity (fig. S2). Methanol selectivity can be as high as $91 \%$ when $\mathrm{H}_{2}$ / $\mathrm{CO}_{2}$ is increased to $4: 1$ with a $\mathrm{CO}_{2}$ conversion of $10 \%$ at $315^{\circ} \mathrm{C}$.

Figure 1 C shows that there is no deactivation of the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst in $\mathrm{CO}_{2}$ hydrogenation, and no deterioration in methanol selectivity for more than 500 hours on stream at least. Stability is a fatal issue for methanol synthesis from either CO or $\mathrm{CO}_{2}$ hydrogenation on most supported metal catalysts because most methanol synthesis catalysts are easily deactivated at higher temperatures due to the sintering effect. To further test the thermal stability of the catalyst, the reaction temperature was elevated from $320^{\circ}$ to $400^{\circ} \mathrm{C}$, kept for 24 hours, and then cooled down to $320^{\circ} \mathrm{C}$. No deactivation is observed after this annealing treatment. To our surprise, this catalyst also shows the resistance to sulfurcontaining molecules in the stream with 50 parts per million (ppm) $\mathrm{SO}_{2}$

Fig. 1. Catalytic performance of the $\mathbf{Z n O}-\mathbf{Z r O}_{\mathbf{2}}$ catalyst. (A) Dependence of catalytic performance at $320^{\circ} \mathrm{C}$ on the $\mathbf{Z n} /(\mathbf{Z n}+\mathrm{Zr})$ molar ratio. Inset: purple, normalized activities for $\mathrm{ZnO}, 13 \% \mathrm{ZnO}_{\mathrm{ZrO}}^{2}$, and $\mathrm{ZrO}_{2}$ by specific surface area; dark yellow, normalized activities for mechanically mixed ZnO and ZrO in the same composition. (B) Catalytic performance at the reaction temperatures from $200^{\circ}$ to $380^{\circ} \mathrm{C}$ with $\mathrm{H}_{2} / \mathrm{CO}_{2}=3: 1$ and $4: 1$. (C) Catalyst stability test in 550 hours. (D) Catalyst stability toward the S-containing molecules ( $50 \mathrm{ppm} \mathrm{H}_{2} \mathrm{~S}$ or $\mathrm{SO}_{2}$ in Ar ) and annealing. In S experiments, there are two gas paths: one is $50 \mathrm{ppm} \mathrm{H}_{2} \mathrm{~S}\left(\mathrm{SO}_{2}\right) / \mathrm{Ar}$ and the other is $\mathrm{CO}_{2} / \mathrm{H}_{2} / \mathrm{Ar}$. Pulsing experiment was carried out by turning on the S gas for 30 min and 60 min and then turning off after the $\mathrm{CO}_{2}+\mathrm{H}_{2}$ reaction reached its steady state. After several pulses, the two gas paths were turned on simultaneously. Standard reaction conditions: $5.0 \mathrm{MPa}, \mathrm{H}_{2} / \mathrm{CO}_{2}=3: 1,320^{\circ} \mathrm{C}, \mathrm{GHSV}=24,000 \mathrm{ml} /(\mathrm{g}$ hour), using a tubular fixedbed reactor with the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst.
or $\mathrm{H}_{2} \mathrm{~S}$ (Fig. 1D). The sulfur-containing molecules are always present in $\mathrm{CO}_{2}$ sources from flue gas produced from coal or biomass burning. Therefore, the high stability of the catalyst toward the sulfur-containing molecules makes the catalyst viable in industrial processes and superior to supported metal catalysts.

X-ray diffraction (XRD) patterns show that the $\mathrm{ZrO}_{2}$ prepared by the coprecipitation method is mainly in the monoclinic phase mixed with some in the tetragonal phase (Fig. 2A and fig. S3). Adding ZnO ( 5 to $33 \%$ ) to $\mathrm{ZrO}_{2}$ leads to the phase change of $\mathrm{ZrO}_{2}$ from monoclinic to tetragonal or cubic (not distinguishable from tetragonal). The phase of ZnO was detected for samples with ZnO concentrations of up to $50 \%$, indicating that the $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution might be formed with ZnO contents in the range below $50 \%$. The interplanar spacing of $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$, which is ca. 0.29 nm (Fig. 2 B and fig. S 4 ), is attributed to the tetragonal $\mathrm{ZrO}_{2}$ (011). However, element distribution analysis shows that Zn is highly dispersed in $\mathrm{ZrO}_{2}$ (Fig. 2C). Considering that the ionic radius of $\mathrm{Zn}^{2+}(0.74 \AA)$ is smaller than that of $\mathrm{Zr}^{4+}$ ( $0.82 \AA$ ) (26), the interplanar spacing would be decreased when $\mathrm{Zn}^{2+}$ is incorporated into the lattice of $\mathrm{ZrO}_{2}$. This is confirmed with the XRD results that the (011) spacing of $\mathrm{ZrO}_{2}$ narrows, and the XRD from the (011) spacing of $\mathrm{ZrO}_{2}$ shifts to a higher angle when the Zn concentration is increased from 5 to $33 \%$. These facts further affirm the conclusion that $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ is in a solid solution state, with Zn incorporated into the $\mathrm{ZrO}_{2}$ lattice matrix (27).

Raman spectroscopy was used to further characterize the phase structure of the $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution catalyst. Raman spectroscopy with different laser sources could detect phases in different depths due
to light absorption and light scattering $\left\{I \propto(1 / \lambda)^{4}\right\} . \mathrm{ZnO}-\mathrm{ZrO}_{2}$ exhibits a strong ultraviolet-visible (UV-vis) absorption band at 215 nm (fig. S5A), so the shorter wavelength laser detects the phase in a relatively shallow layer. Therefore, the Raman spectroscopy with laser sources at 244,266 , and 325 nm could gradually detect phases from the skin layer to the bulk of the catalyst (fig. S5B) $(28,29)$. The phase near the utmost skin layer (the depth of skin layer is approximately 2 nm ) is sensitively detected by UV Raman spectroscopy with a 244 -nm excitation laser, as shown in Fig. 2D. The appearance of Raman peaks at 305, 342, and $378 \mathrm{~cm}^{-1}$ indicates that the skin layer of pure $\mathrm{ZrO}_{2}$ is in monoclinic. For 5 to $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ samples, when increasing the ZnO content from 5 to $13 \%$, the spectrum evolved slightly from that of the monoclinic phase to one with an additional peak at $269 \mathrm{~cm}^{-1}$, although the peaks in the range of 300 to $500 \mathrm{~cm}^{-1}$ are similar to those of $\mathrm{ZrO}_{2}$. The weak peak at $269 \mathrm{~cm}^{-1}$ is due to the characteristics of the tetragonal phase $(30,31)$. This suggests that the skin layer phase of $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ might be in the transition state between monoclinic and tetragonal phases. The Raman spectrum with a $266-\mathrm{nm}$ laser is dominated by peaks at 269 and $317 \mathrm{~cm}^{-1}$ (Fig. 2D and fig. S5, C and D), which are due to the tetragonal phase of $\mathrm{ZrO}_{2}$, and the Raman spectrum with a $325-\mathrm{nm}$ laser gives a typical peak at $564 \mathrm{~cm}^{-1}$ due to the cubic phase. These results suggest that underneath the skin layer of $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ is in the tetragonal phase, whereas the bulk is in the cubic phase. Note that the Raman signal of the monoclinic phase is much stronger than that of tetragonal and cubic phases. Therefore, the distorted phase in the surface region could be obscured by the monoclinic phase in Raman spectra. X-ray photoelectron spectroscopy (XPS) results show that the

(B) High-resolution transmission electron microscopy (HRTEM) and (C) aberrationcorrected scanning TEM-high-angle annular dark-field images and element distribution of $13 \% \mathrm{ZnO}^{-\mathrm{ZrO}}$ 2. (D) Raman spectra of $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ with $244-\mathrm{nm}$ laser (solid line), 266-nm laser (pink dot line), and 325-nm laser (dark yellow dot line). (E) Zn concentration in the surface region of $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ measured by XPS. (F) Schematic description of the $\mathrm{ZnO}-\mathrm{ZrO} 2$ solid solution catalyst model.

Zn concentration in the surface region is higher than the theoretical value (Fig. 2E), suggesting that Zn is relatively rich there. These facts indicate that the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst is an imperfect solid solution in phase transition from skin layer to bulk, as schematically depicted in Fig. 2F.
$\mathrm{CO}_{2}$-TPD (temperature-programmed desorption of $\mathrm{CO}_{2}$ ) of catalysts shows that there are two desorption peaks: low $\left(<320^{\circ} \mathrm{C}\right)$ and high ( $>320^{\circ} \mathrm{C}$ ) temperature (Fig. 3A). The total $\mathrm{CO}_{2}$ adsorption amounts for $\mathrm{ZrO}_{2}, 13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$, and $\mathrm{ZrO}_{2}$ are 100,82 , and $82 \mathrm{mmol} / \mathrm{m}^{2}$, respectively. $\mathrm{CO}_{2}$ absorption capability below the reaction temperature, $320^{\circ} \mathrm{C}$, follows the order $\mathrm{ZrO}_{2}$ (100) $>13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ (91) >> ZnO (32) (inset in Fig. 3A). $\mathrm{ZrO}_{2}$ adsorbs much more $\mathrm{CO}_{2}$ than does ZnO below the reaction temperature. Furthermore, the surface component of $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ is about $78 \% \mathrm{Zr}$ and $22 \% \mathrm{Zn}$ obtained from XPS (Fig. 2E), and the amount of adsorbed $\mathrm{CO}_{2}$ on $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ is about the same as that estimated from the sum of the amounts of $\mathrm{CO}_{2}$ adsorbed on the individual components based on that normalized by specific surface area (inset in Fig. 3A). Therefore, it could be deduced that, at low temperatures, most of the $\mathrm{CO}_{2}$ adsorbed by $13 \%$ $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ is on the Zr sites.

The rate of HD formation from the $\mathrm{H}_{2}-\mathrm{D}_{2}$ exchange reaction normalized by specific surface area is as follows: $\mathrm{ZnO}(100)>13 \% \mathrm{ZnO}-$ $\mathrm{ZrO}_{2}$ (89) $\gg \mathrm{ZrO}_{2}$ (7) (Fig. 3B), indicating that ZnO has much higher
activity in the $\mathrm{H}_{2}-\mathrm{D}_{2}$ exchange reaction than $\mathrm{ZrO}_{2}$. Surprisingly, the activity of $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ is also much greater than that of $\mathrm{ZrO}_{2}$, although $\mathrm{ZrO}_{2}$ comprises $78 \%$ of the catalyst's specific surface area. If the two components kept their own activity in the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst, the sum of their activities would be about 27, far less than the experimental result, which is 89 . This suggests that there is a strong synergetic effect in the $\mathrm{H}_{2}$ activation between the two sites, Zn and Zr . XPS shows that the binding energy of Zn in $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ is evidently reduced compared to that of ZnO , whereas the binding energy of Zr in $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ remains intact (fig. S6). This indicates that the electronic property of the Zn site is modified by the neighboring Zr site. $\mathrm{H}_{2}$-TPR (temperature-programmed reduction of $\mathrm{H}_{2}$ ) also shows that $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ is more easily reduced than ZnO and $\mathrm{ZrO}_{2}$ (fig. S7). Therefore, on the basis of the $\mathrm{H}_{2}-\mathrm{D}_{2}$ exchange reaction and catalytic $\mathrm{CO}_{2}$ hydrogenation reaction results, we could conclude that it is the synergetic effect between the Zn and Zr sites in the $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution catalyst that significantly promotes the activation of $\mathrm{H}_{2}$ and $\mathrm{CO}_{2}$ and consequently results in the excellent catalytic performance in $\mathrm{CO}_{2}$ hydrogenation. This is also shown experimentally from the fact that the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution catalyst exhibits much higher activity and methanol selectivity than does mechanically mixed $\mathrm{ZnO}+\mathrm{ZrO}_{2}$ (13:87) or the supported $13 \% \mathrm{ZnO} / \mathrm{ZrO}_{2}$ catalyst in $\mathrm{CO}_{2}$ hydrogenation (Fig. 1A, table S2, and fig. S8).

(B) $\mathrm{H}_{2}$ - $\mathrm{D}_{2}$ exchange reaction on ZnO , $\mathrm{ZrO}_{2}$, and $13 \% \mathrm{ZnO}_{\mathrm{ZrO}}^{2}$ at $280^{\circ} \mathrm{C}$. Purple, normalized rate by specific surface area; dark yellow, normalized activities for mechanically mixed ZnO and $\mathrm{ZrO} \mathrm{O}_{2}$ in the same composition as $13 \% \mathrm{ZnO}_{\mathrm{ZrO}}^{2}$.

To understand the reaction mechanism on the solid solution catalyst, the surface species evolved in the reaction were monitored by in situ diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS) (Fig. 4A). $\mathrm{HCOO}^{*}$ and $\mathrm{H}_{3} \mathrm{CO}^{*}$ species were observed and identified (table S3) (32-37). The infrared (IR) peaks at 1595 and $1370 \mathrm{~cm}^{-1}$ are assigned to the asymmetric and symmetric OCO stretching vibrations, respectively, of adsorbed bidentate $\mathrm{HCOO}^{*}$ species. The peaks at 2878 and $1382 \mathrm{~cm}^{-1}$ are assigned to the stretching vibration $v(\mathrm{CH})$ and bending vibration $\delta(\mathrm{CH})$, respectively. The peaks at 2931, 2824, and $1046 \mathrm{~cm}^{-1}$ are attributed to the $\mathrm{H}_{3} \mathrm{CO}^{*}$ species. The peaks at 2878 and $2824 \mathrm{~cm}^{-1}$ were used to follow the concentration changes of $\mathrm{HCOO}^{*}$ and $\mathrm{H}_{3} \mathrm{CO}^{*}$ species. Figure 4 B shows the varying tendency of the two species with time, and the products were detected by mass spectrometry (MS) (38). It can be seen that the surface $\mathrm{HCOO}^{*}$ (based on IR peak intensity) reaches a steady state after a reaction for 30 min , whereas it takes 90 min for $\mathrm{H}_{3} \mathrm{CO}^{*}$ to reach its steady state. However, $\mathrm{CH}_{3} \mathrm{OH}$ detected by MS reaches a steady state after 60 min . When $\mathrm{CO}_{2}+$ $\mathrm{H}_{2}$ was substituted for $\mathrm{CO}_{2}+\mathrm{D}_{2}$, the amount of $\mathrm{HCOO}^{*}$ and $\mathrm{CH}_{3} \mathrm{OH}$ decreases (Fig. 4B and fig. S9), whereas the amount of $\mathrm{DCOO}^{*}$ and $\mathrm{CD}_{3} \mathrm{OD}$ increases. The $\mathrm{DCOO}^{*}$ species appears and reaches a steady state after ca. 90 min ; meanwhile, the total D-substituted products reach a steady state after ca. 90 min , as detected by MS. It is speculated that the $\mathrm{HCOO}^{*}$ and $\mathrm{CH}_{3} \mathrm{O}^{*}$ species are likely intermediates of the $\mathrm{CO}_{2}$ hydrogenation on the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution catalyst. To verify the possible surface intermediate species, the IR spectra of surface species formed from $\mathrm{CO}_{2}+\mathrm{H}_{2}$ were recorded as those in Fig. 4A, then the reaction gas phase of $\mathrm{CO}_{2}+\mathrm{H}_{2}$ was switched to $\mathrm{D}_{2}$, and the IR peaks at 2878 and $2824 \mathrm{~cm}^{-1}$ of the $\mathrm{HCOO}^{*}$ and $\mathrm{H}_{3} \mathrm{CO}^{*}$ species, respectively, are declined rapidly and disappeared in 60 min (Fig. 4C). Correspondingly, two new peaks at 2165 and $2052 \mathrm{~cm}^{-1}$ due to the $\mathrm{DCOO}^{*}$ and $\mathrm{HD}_{2} \mathrm{CO}^{*}$ species appeared first, grew somewhat, and then disappeared slowly. MS displays the $\mathrm{HD}_{2} \mathrm{COD}$ product responding to the disappearance of the surface $\mathrm{HCOO}^{*}$ and $\mathrm{H}_{3} \mathrm{CO}^{*}$ species at the same time (Fig. 4D). These evidences indicate that the surface $\mathrm{HCOO}^{*}$ and $\mathrm{H}_{3} \mathrm{CO}^{*}$ species on the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution catalyst can be hydrogenated to methanol.

Density functional theory (DFT) calculations were performed to understand the reaction mechanisms (details in the Supplementary Materials). Figure 5 shows the reaction diagram of $\mathrm{CO}_{2}$ hydrogenation to methanol on the surface of $\mathrm{ZnO}-\mathrm{ZrO}_{2}$. Two major reaction pathways
were evaluated, that is, formate and CO pathways $(39,40) . \mathrm{H}_{2}$ is adsorbed and dissociated on the Zn site. $\mathrm{CO}_{2}$ is adsorbed on the coordination unsaturated Zr site (figs. S10 to S12). The formation of $\mathrm{HCOO}^{*}$ species via $\mathrm{CO}_{2}{ }^{*}$ hydrogenation is energetically very favorable, which is coherent with the in situ DRIFTS observations. The terminal oxygen of $\mathrm{H}_{2} \mathrm{COO}^{*}$ (formed by $\mathrm{HCOO}^{*}$ hydrogenation) can be protonated by an $\mathrm{OH}^{*}$ group and forms a $\mathrm{H}_{2} \mathrm{COOH}^{*}$ species, of which the $\mathrm{C}-\mathrm{O}$ bond is cleaved and thereby generates $\mathrm{H}_{2} \mathrm{CO}^{*}$ and $\mathrm{OH}^{*}$ binding on Zr and Zn sites, respectively. The process of $\mathrm{H}_{2} \mathrm{COO}^{*} \rightarrow \mathrm{H}_{2} \mathrm{CO}^{*}+\mathrm{H}_{2} \mathrm{O}^{*}$ is thermodynamically unfavorable ( $\Delta_{\mathrm{r}} \mathrm{G}=1.26 \mathrm{eV}$ ). The desorption energy of water from the surface is $0.60 \mathrm{eV} . \mathrm{H}_{2} \mathrm{CO}^{*}+\mathrm{H}^{*} \rightarrow \mathrm{H}_{3} \mathrm{CO}^{*}$ is an energetically favorable process $\left(\Delta_{\mathrm{r}} G^{\ddagger}=-2.32 \mathrm{eV}\right) . \mathrm{H}_{3} \mathrm{CO}^{*}$ species identified by theoretical calculation corresponds to the second most stable reaction intermediate detected by in situ DRIFTS. Finally, methanol is formed by $\mathrm{H}_{3} \mathrm{CO}^{*}$ protonation.

In principle, it is also possible to first produce $\mathrm{CO}^{*}$ from $\mathrm{CO}_{2}{ }^{*}$ and then for $\mathrm{CO}^{*}$ to undergo consecutive hydrogenation to form methanol. As shown in Fig. $5, \mathrm{OCOH}^{*}$ is much less stable than $\mathrm{HCOO}^{*}$. Furthermore, the reaction of $\mathrm{CO}_{2}{ }^{*}$ to $\mathrm{OCOH}^{*}$ needs to overcome a barrier $\left(\Delta G^{\ddagger}\right)$ of 0.69 eV , which is quite unfavorable compared to the barrier-less process of $\mathrm{CO}_{2}{ }^{*}+\mathrm{H}^{*} \rightarrow \mathrm{HCOO}^{*}$. Even if a fair amount of $\mathrm{OCOH}^{*}$ can be present during the reaction, the weakly bonded $\mathrm{CO}^{*}$ produced from $\mathrm{OCOH}^{*}$ prefers to desorb from the surface rather than undergo hydrogenation reactions. Therefore, it is concluded that $\mathrm{CO}_{2}$ hydrogenation to methanol on the surface of $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ is through the formate pathway.

DFT calculations also suggest that the methanol selectivity of ZnO $\mathrm{ZrO}_{2}$ is higher than that of $\mathrm{ZnO}(41,42)$. The formate pathway was evaluated on ZnO for $\mathrm{CO}_{2}$ hydrogenation to methanol (figs. S 13 to S16). The process of $\mathrm{H}_{2} \mathrm{COO}^{*} \rightarrow \mathrm{H}_{2} \mathrm{CO}^{*}+\mathrm{H}_{2} \mathrm{O}^{*}$ is the most unfavorable step in thermodynamics. The energy barrier of this step is 1.37 eV , higher than that for $\mathrm{ZnO}-\mathrm{ZrO}_{2}(1.27 \mathrm{eV})$. Therefore, $\mathrm{ZnO}-$ $\mathrm{ZrO}_{2}$ has a relatively higher methanol selectivity and a lower CO selectivity than ZnO . The results are consistent with the experimental results as well. The high methanol selectivity of $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution is attributed to the synergetic effect in $\mathrm{H}_{2}$ activation between the Zn and Zr sites, and the simultaneous activation of $\mathrm{H}_{2}$ and $\mathrm{CO}_{2}$ on the neighboring sites, Zn and Zr , respectively.

There has been an opinion that the $\mathrm{CO}_{2}$ hydrogenation is similar to the CO hydrogenation, and the pathway of $\mathrm{CO}_{2}$ to methanol is a CO

Fig. 4. Characterization of surface species. (A) In situ DRIFT spectra of surface species formed from the $\mathrm{CO}_{2}+\mathrm{H}_{2}$ reaction. (B) DRIFT-MS of $\mathrm{CO}_{2}+\mathrm{H}_{2}$ and $\mathrm{CO}_{2}+\mathrm{D}_{2}$ reactions on $13 \%{\mathrm{ZnO}-\mathrm{ZrO}_{2} \text {. (C) In situ DRIFT spectra of surface species from } \mathrm{CO}_{2}+\mathrm{H}_{2} \text { and subsequently switched to } \mathrm{D}_{2} \text {. (D) DRIFT-MS of } \mathrm{CO}+\mathrm{H}_{2} \text { and subsequently }}^{\text {( }}$ switched to $\mathrm{D}_{2}$. Reaction conditions: $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst, $0.1 \mathrm{MPa}, 280^{\circ} \mathrm{C}, 10 \mathrm{ml} / \mathrm{min} \mathrm{CO}_{2}+30 \mathrm{ml} / \mathrm{min} \mathrm{H}_{2}\left(\mathrm{D}_{2}\right)$.
pathway, where it is assumed that $\mathrm{CO}_{2}$ hydrogenation to methanol is first to CO (by RWGS) and then the CO is hydrogenated to methanol $(13,18)$. To clarify this issue, the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst was also evaluated for $\mathrm{CO}+\mathrm{H}_{2}$ (fig. S17). Besides methanol as the major product, some additional products including dimethyl ether (DME) and methane were detected. The STY of methanol on the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst from $\mathrm{CO}_{2}$ hydrogenation is 2.5 times of that from CO hydrogenation at their optimized temperatures for methanol production. These facts indicate that the $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ solid solution catalyst is especially active for $\mathrm{CO}_{2}$ hydrogenation to methanol.

Whether formate species are involved in the methanol synthesis for Cu-based catalysts has been a controversial issue. For example, the latest
reports on $\mathrm{Cu} / \mathrm{ZrO}_{2}$ from Larmier et al. (12) and Kattel et al. (13) proposed very different mechanisms. According to the former, formate species was the reaction intermediate, whereas the latter stated that formate was a spectator. Very recently, Kattel et al. (10) proposed that the formate was an intermediate species for methanol on the $\mathrm{Cu} / \mathrm{ZnO}$ catalyst. Because our $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst is very different from the Cu -based one, the methanol formation mechanism might also be different. Our isotope labeling experiment and DFT calculation show that the formate species can be hydrogenated to methanol. However, at the moment, we still could not reach the conclusion that the formate species is the major active intermediate for methanol formation because it is difficult to determine how much of the observed formate species contributed to the methanol production.

Fig. 5. DFT calculations. Reaction diagram [energy (E) and Gibbs free energy (G) at a typical reaction temperature of $593 \mathrm{~K}^{\mathrm{K}}$ of $\mathrm{CO}_{2}$ hydrogenation to methanol on the (101) surface of the tetragonal $\mathrm{ZnO}_{-2 \mathrm{ZO}}^{2}$ model.

To compare the catalytic performance difference between the ZnO $\mathrm{ZrO}_{2}$ catalyst and Cu -based catalysts, a standard $\mathrm{Cu} / \mathrm{ZnO} / \mathrm{Al}_{2} \mathrm{O}_{3}$ catalyst was evaluated for $\mathrm{CO}_{2}$ hydrogenation. The methanol selectivity varies from 82 to $5 \%$ at reaction temperatures from $200^{\circ}$ to $320^{\circ} \mathrm{C}$ under identical conditions as those used for the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst (fig. S18). The results are similar to those reported for the $\mathrm{Cu} / \mathrm{ZnO} /$ $\mathrm{Al}_{2} \mathrm{O}_{3}$ catalyst in the literature $(43,44)$. It is seen that the selectivity of methanol on the Cu-based catalyst is lower than that on the $13 \% \mathrm{ZnO}-$ $\mathrm{ZrO}_{2}$ catalyst and markedly decreases when the reaction temperature was elevated. In addition, the stability of the $\mathrm{Cu} / \mathrm{ZnO} / \mathrm{Al}_{2} \mathrm{O}_{3}$ catalyst
was tested for sintering and sulfur poisoning (fig. S19). The activity of the catalyst shows a decrease of $25 \%$ for the reaction in 500 hours, and the activity drops even more quickly in the presence of 50 ppm SO 2 ; however, the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst does not show any deactivation in 500 hours and $\mathrm{SO}_{2}$ does not change the activity obviously either (Fig. 1, C and D ). A controlled experiment demonstrated that the $\mathrm{Cu} / \mathrm{ZnO} /$ $\mathrm{Al}_{2} \mathrm{O}_{3}$ catalyst was deactivated severely (at least $25 \%$ drop in activity) after a thermal treatment at $320^{\circ} \mathrm{C}$, whereas the $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst does not show evident deactivation after a thermal treatment even at $400^{\circ} \mathrm{C}$ (Fig. 1D).

This work demonstrates that the binary metal oxide $\mathrm{ZnO}-\mathrm{ZrO}_{2}$ in the solid solution state is an active catalyst for converting $\mathrm{CO}_{2}$ to methanol with high selectivity and stability. This solid solution catalyst opens a new avenue for $\mathrm{CO}_{2}$ conversion by taking advantage of the synergetic effect between its multicomponents.

## MATERIALS AND METHODS

## Catalyst preparation

The $13 \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalyst was taken as a typical example to describe the synthesis procedures: 0.6 g of $\mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and 5.8 g of $\mathrm{Zr}\left(\mathrm{NO}_{3}\right)_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ were dissolved in a flask by 100 ml of deionized water. The precipitant of the $100-\mathrm{ml}$ aqueous solution of 3.06 g of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}$ was added to the aforementioned solution (at a flow rate of $3 \mathrm{ml} / \mathrm{min}$ ) under vigorous stirring at $70^{\circ} \mathrm{C}$ to form a precipitate. The suspension was continuously stirred for 2 hours at $70^{\circ} \mathrm{C}$, followed by cooling down to room temperature, filtering, and washing three times with deionized water. The filtered sample was dried at $110^{\circ} \mathrm{C}$ for 4 hours and calcined at $500^{\circ} \mathrm{C}$ in static air for 3 hours. Other $x \% \mathrm{ZnO}-\mathrm{ZrO}_{2}$ catalysts were prepared following the same method. The supported $\mathrm{ZnO} / \mathrm{ZrO}_{2}$ catalyst was prepared by wet impregnation. $\mathrm{ZrO}_{2}$ support was synthesized according to the coprecipitation method described above. $\mathrm{ZrO}_{2}(1 \mathrm{~g})$ was immersed in 25 ml of aqueous solution of $\mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2}$ with stoichiometric amount. The mixture was stirred at $110^{\circ} \mathrm{C}$ until the water had completely volatilized and then calcined at $500^{\circ} \mathrm{C}$ in air for 3 hours. The $\mathrm{Cu} / \mathrm{ZnO} /$ $\mathrm{Al}_{2} \mathrm{O}_{3}$ catalyst was prepared by coprecipitation analogous to the procedure described by Behrens and Schlögl (6). Aqueous solution ( 100 ml ) of metal nitrates [ 4.35 g of $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}, 2.68 \mathrm{~g}$ of $\mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, and 1.12 g of $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ ] and aqueous solution $(120 \mathrm{ml})$ of 3.82 g of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ as a precipitant were added dropwise (at a flow rate of $3 \mathrm{ml} / \mathrm{min}$ ) to a glass reactor with a starting volume of 200 ml of deionized water under vigorous stirring at $70^{\circ} \mathrm{C}$. Controlling the pH of precipitation mother liquor to 7 , and aging the precipitate for 2 hours after precipitation, followed by cooling down to room temperature, filtering, and washing seven times with deionized water. The filter cake was dried at $110^{\circ} \mathrm{C}$ for 4 hours and calcined at $350^{\circ} \mathrm{C}$ in static air for 3 hours. The commercial $\mathrm{Cu} / \mathrm{ZnO} / \mathrm{Al}_{2} \mathrm{O}_{3}$ catalyst (C307) was purchased from Nanjing Chemical Industrial Corporation of Sinopec for comparison. All catalysts were pressed, crushed, and sieved to the size of 40 to 80 mesh for the activity evaluation.

## Catalyst evaluation

The activity tests of the catalysts for $\mathrm{CO}_{2}$ hydrogenation to methanol were carried out in a tubular fixed-bed continuous-flow reactor equipped with gas chromatography (GC). Before the reaction, the catalyst ( 0.1 g , diluted with 0.4 g of quartz sand) was pretreated in a $\mathrm{H}_{2}$ or $\mathrm{N}_{2}$ stream ( 0.1 MPa and $20 \mathrm{ml} / \mathrm{min}$ ) at given temperatures. The reaction was conducted under reaction conditions of 1.0 to $5.0 \mathrm{MPa}, 180^{\circ}$ to $400^{\circ} \mathrm{C}, V\left(\mathrm{H}_{2}\right) / V\left(\mathrm{CO}_{2}\right) /$ $V(\mathrm{Ar})=72: 24: 4,64: 32: 4$, or 77:19:5, and GHSV $=5000$ to $33,000 \mathrm{ml} /(\mathrm{ghour})$. The exit gas from the reactor was maintained at $150^{\circ} \mathrm{C}$ and immediately transported to the sample valve of the GC (Agilent 7890B), which was equipped with thermal conductivity (TCD) and flame ionization detectors (FIDs). Porapak N and 5A molecular sieve packed columns ( $2 \mathrm{~m} \times$ 3.175 mm ; Agilent) were connected to TCD, whereas TG-BOND Q capillary columns were connected to FID. The packed column was used for the analysis of $\mathrm{CO}_{2}, \mathrm{Ar}$, and CO , and the capillary column ( $30 \mathrm{~m} \times$ $0.32 \mathrm{~mm} \times 10 \mu \mathrm{~m}$; Thermo Fisher) was used for hydrocarbons, alcohols, and other C-containing products. $\mathrm{CO}_{2}$ conversion [denoted as $\mathrm{X}\left(\mathrm{CO}_{2}\right)$ ] and the carbon-based selectivity [denoted as $S$ (product)] for the carbon-
containing products, including methane, methanol, and DME, were calculated using an internal normalization method. STY of methanol was denoted as STY $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$. All data were collected in 3 hours after the reaction started (unless otherwise specified).
$X\left(\mathrm{CO}_{2}\right), S\left(\mathrm{CH}_{3} \mathrm{OH}\right), S(\mathrm{CO})$, and STY $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ were calculated as follows:

$$
X\left(\mathrm{CO}_{2}\right)=
$$

$$
\begin{aligned}
& \left.\frac{f_{\mathrm{CO}} A_{\mathrm{CO}}+i\left(f_{\mathrm{CH}_{4}} A_{\mathrm{CH}_{4}}+f_{\mathrm{CH}_{3} \mathrm{OH}} A_{\mathrm{CH}_{3} \mathrm{OH}}+2 f_{\mathrm{CH}_{3} \mathrm{OCH}_{3}} A_{\mathrm{CH}_{3} \mathrm{OCH}}^{3}\right.}{}\right), \\
& i=\frac{f_{\mathrm{CH}_{4}-\mathrm{TCD}} A_{\mathrm{CH}_{4}-\mathrm{TCD}}}{f_{\mathrm{CH}_{4}-\mathrm{FID}} A_{\mathrm{CH}_{4}-\mathrm{FID}}} \\
& S\left(\mathrm{CH}_{3} \mathrm{OH}\right)= \\
& \frac{f_{\mathrm{CH}_{3} \mathrm{OH}} A_{\mathrm{CH}_{3} \mathrm{OH}}}{f_{\mathrm{CO}} A_{\mathrm{CO}}+i\left(f_{\mathrm{CH}_{4}} A_{\mathrm{CH}_{4}}+f_{\mathrm{CH}_{3} \mathrm{OH}} A_{\mathrm{CH}_{3} \mathrm{OH}}+2 f_{\mathrm{CH}_{3} \mathrm{OCH}_{3}} A_{\mathrm{CH}_{3} \mathrm{OCH}_{3}}\right)} \\
& S(\mathrm{CO})= \\
& \frac{f_{\mathrm{CO}} A_{\mathrm{CO}}}{f_{\mathrm{CO}} A_{\mathrm{CO}}+i\left(f_{\mathrm{CH}_{4}} A_{\mathrm{CH}_{4}}+f_{\mathrm{CH}_{3} \mathrm{OH}} A_{\mathrm{CH}_{3} \mathrm{OH}}+2 f_{\mathrm{CH}_{3} \mathrm{OCH}_{3}} A_{\mathrm{CH}_{3} \mathrm{OCH}_{3}}\right)} \\
& \operatorname{STY}\left(\mathrm{CH}_{3} \mathrm{OH}\right)=\frac{\mathrm{GHSV}}{S A \times 22.4} \times V \%\left(\mathrm{CO}_{2}\right) \times X\left(\mathrm{CO}_{2}\right) \times S\left(\mathrm{CO}_{2}\right) \\
& \times M_{\mathrm{CH}_{3} \mathrm{OH}}
\end{aligned}
$$

## Catalyst characterization

The XRD results were collected on a Philips PW1050/81 diffractometer operating in Bragg-Brentano focusing geometry and using $\mathrm{Cu} \mathrm{K} \alpha$ radiation ( $\lambda=1.5418 \AA$ ) from a generator operating at 40 kV and 30 mA . TEM images were obtained with a JEM- 2100 microscope at 200 kV . The samples were prepared by placing a drop of nanoparticle ethanol suspension onto a lacey support film and by allowing the solvent to evaporate. Element mappings were obtained with a JEM-ARM200F microscope. UV-vis spectrum was obtained with a PerkinElmer 25 UV-vis spectrometer in the wavelength range of 350 to 800 nm , with a resolution of 1 nm . The UV laser source ( 244 and 266 nm ) was a Coherent Innova 300 C FreD continuous wave UV laser equipped with an intracavity frequency-doubling system using a BBO crystal to produce second harmonic generation outputs at different wavelengths. The UV laser source ( 325 nm ) was a Coherent DPSS 325 Model $200325-\mathrm{nm}$ single-frequency laser. UV Raman spectra were recorded on a homeassembled UV Raman spectrograph using a Jobin-Yvon T64000 triple-stage spectragraph with a spectral resolution of $2 \mathrm{~cm}^{-1}$ coupled with a UV-sensitive charge-coupled device detector. XPS was performed using a Thermo Fisher ESCALAB 250Xi with Al K radiation ( 15 kV , $10.8 \mathrm{~mA}, h \nu=1486.6 \mathrm{eV})$ under ultrahigh vacuum $\left(5 \times 10^{-7} \mathrm{~Pa}\right)$, calibrated internally by the carbon deposit $\mathrm{C}(1 \mathrm{~s})\left(E_{\mathrm{b}}=284.6 \mathrm{eV}\right)$. The $\mathrm{CO}_{2} /$ $\mathrm{H}_{2}$-TPD of the catalysts was conducted with an adsorption/desorption system. A $100-\mathrm{mg}$ sample was treated in situ in a $\mathrm{H}_{2}$ or He stream ( $30 \mathrm{ml} / \mathrm{min}$ ) at $300^{\circ} \mathrm{C}$ for 1 hour, flushed by a He stream ( $30 \mathrm{ml} / \mathrm{min}$ ) at $300^{\circ} \mathrm{C}$ for 30 min to clean its surface, and then cooled to $50^{\circ} \mathrm{C}$. It was then returned to the $\mathrm{CO}_{2} / \mathrm{H}_{2}$ stream for 60 min , and afterward, the sample was flushed by the He stream until a stable baseline was obtained. TPD measurements were then conducted from $50^{\circ}$ to $600^{\circ} \mathrm{C}$.

The temperature increase rate was $10^{\circ} \mathrm{C} / \mathrm{min}$. The changes of $\mathrm{CO}_{2} / \mathrm{H}_{2}$ were monitored by AutoChem 2910 with a TCD detector. The system was coupled to an OmniStar 300 mass spectrometer to detect other products in the gas phase. The TPR of the catalysts was conducted with the same system used in TPD. The samples were treated with He at $130^{\circ} \mathrm{C}$ for 1 hour, and then $5 \% \mathrm{H}_{2} / \mathrm{Ar}$ was used as carrier gas of TCD to conduct the TPR with $10^{\circ} \mathrm{C} / \mathrm{min}$ from $50^{\circ}$ to $800^{\circ} \mathrm{C} . \mathrm{H}_{2}-\mathrm{D}_{2}$ exchange experiments were performed in a flow reactor at $280^{\circ} \mathrm{C}$. The formation rate of HD was measured by mass signal intensity (ion current). The 0.1 g sample was reduced with $\mathrm{H}_{2}(10 \mathrm{ml} / \mathrm{min})$ at $280^{\circ} \mathrm{C}$ for 1 hour. Then, $\mathrm{D}_{2}$ ( $10 \mathrm{ml} / \mathrm{min}$ ) was mixed with $\mathrm{H}_{2}$ and together passed the catalyst sample. Reaction products $\mathrm{HD}, \mathrm{H}_{2}$, and $\mathrm{D}_{2}$ were analyzed with a mass spectrometer (GAM200, InProcess Instruments). The mass/charge ratio ( $\mathrm{m} / \mathrm{z}$ ) values used are 2 for $\mathrm{H}_{2}, 4$ for $\mathrm{D}_{2}$, and 3 for HD. In situ DRIFTS investigations were performed using a Fourier transform infrared (FTIR) spectrometer (Thermo Fisher, Nicolet 6700) equipped with a mercury cadmium telluride detector. Before measurement, each catalyst was treated with $\mathrm{H}_{2}$ at $300^{\circ} \mathrm{C}$ for 2 hours and then purged with $\mathrm{N}_{2}$ at $450^{\circ} \mathrm{C}$ for 2 hours. The catalyst was subsequently cooled down to $280^{\circ} \mathrm{C}$. The background spectrum was obtained at $280^{\circ} \mathrm{C}$ in $\mathrm{N}_{2}$ flow. Then, the sample was exposed to a $\mathrm{CO}_{2} / \mathrm{H}_{2}$ mixture ( $10 \mathrm{ml} / \mathrm{min} \mathrm{CO}_{2}$ and $30 \mathrm{ml} / \mathrm{min} \mathrm{H}_{2}$ ) for 90 min . The in situ DRIFT spectra were recorded by collecting 64 scans at a resolution of $4 \mathrm{~cm}^{-1}$. IR-MS experiments were performed by combining DRIFTS and MS. The products detected by MS were warmed to be the gas phase. The specific surface area was determined by $\mathrm{N}_{2}$ adsorption using a Micromeritics ASAP 2020 system.

## DFT calculation

Spin-polarized DFT calculations were performed with the VASP 5.3.5 package (45). The generalized gradient approximation based on Perdew-Burke-Ernzerhof exchange-correlation functional and projected augmented wave method accounting for valence-core interactions were used throughout (46). The kinetic energy cutoff of the plane-wave basis set was set to 400 eV . A Gaussian smearing of the population of partial occupancies with a width of 0.1 eV was used during iterative diagonalization of the Kohn-Sham Hamiltonian. The threshold for energy convergence in each iteration was set to $10^{-5} \mathrm{eV}$. Convergence was assumed when forces on each atom were less than $0.05 \mathrm{eV} / \AA$ in the geometry optimization. The minimum-energy reaction pathways and the corresponding transition states were determined using the nudged elastic band method with improved tangent estimate (CI-NEB) implemented in VASP (47). The maximum energy geometry along the reaction path obtained with the NEB method was further optimized using a quasi-Newton algorithm. In this step, only the adsorbates and the active center of the metal site were relaxed. Frequency analysis of the stationary points was performed by means of the finite difference method as implemented in VASP 5.3.5. Small displacements ( $0.02 \AA$ ) were used to estimate the numerical Hessian matrix. The transition states were confirmed by the presence of a single imaginary frequency corresponding to the specific reaction path.

Both the unit lattice vectors and atoms of hexagonal wurtzite structure ZnO were fully optimized in the first step. The optimized lattice parameters for bulk ZnO are $a=b=3.289 \AA$ and $c=5.312 \AA$, which are coherent with the experimental values of $a=b=3.249 \AA$ and $c=$ $5.206 \AA$ (48). The Zn -terminated (0001) polar surface slab model of ZnO was constructed by a periodic $4 \times 4 \times 1$ supercell with five Zn -O sublayers and separated by a vacuum layer of $15 \AA$ Along the surface normal direction to avoid spurious interactions between the periodic slab models. The top two $\mathrm{Zn}-\mathrm{O}$ sublayers were fully relaxed, whereas
the lowest three layers were fixed at the optimized atomic bulk positions during all the surface calculations. Monkhorst-Pack mesh of $8 \times 8 \times 6$ $k$-points was used to sample the Brillouin zone for the bulk ZnO , and it was restricted to $2 \times 2 \times 1 k$-points for the supercell surface slab model due to the computational time demands. To eliminate the artificial dipole moment within the slab model of polar ZnO surface, all the oxygen atoms at the bottom of the slab model were saturated by adding pseudo-hydrogen atoms, each containing a positive charge of $+0.5|e|$. This strategy effectively removes the internal polarization within the slab, as indicated by the flatter projection of the Hartree potential along the direction of the surface normal compared to other dipole correction methods.

The optimized lattice parameters for tetragonal $\mathrm{ZrO}_{2}$ bulk are $a=$ $b=3.684 \AA$ and $c=5.222 \AA$, which are in line with the experimental values of $a=b=3.612 \AA$ and $c=5.212 \AA$ (49). The most stable (101) surface of the $\mathrm{ZrO}_{2}$ tetragonal phase was simulated by a $2 \times 3 \times 1$ supercell slab model, including three $\mathrm{ZrO}_{2}$ sublayers (each includes two oxygen atomic layers and one Zr atomic layer), separated by a vacuum layer with a thickness of $15 \AA$ along the surface normal direction to avoid spurious interactions between the periodic slab models. To take into account the effect of $\mathrm{Zn}^{2+}$ doping, one of the $\mathrm{Zr}^{4+}-\mathrm{O}^{2-}$ moiety on the surface was replaced by a $\mathrm{Zn}^{2+}$ cation and an oxygen vacancy $\left(\mathrm{Zn}^{2+}-\mathrm{O}_{\mathrm{v}}\right)$. The atoms of the top $\mathrm{ZrO}_{2}$ layer were fully optimized, whereas the other two $\mathrm{ZrO}_{2}$ layers at the bottom were fixed at their optimized bulk positions throughout the surface calculations. The on-site Coulomb correction for the Zr 4 d states of the $\mathrm{ZrO}_{2}$ bulk and $\mathrm{Zn}-\mathrm{ZrO}_{2}$ surface was included by DFT $+U$ approach with a $U_{\text {eff }}$ value of 4.0 eV . $K$-point grids of $8 \times 8 \times 6$ and $2 \times 2 \times 1$ generated by Monkhorst-Pack scheme were used to sample the Brillouin zones of the $\mathrm{ZrO}_{2}$ bulk and $\mathrm{Zn}-\mathrm{ZrO}_{2}$ supercell surface slab model, respectively.

The adsorption energy of the reaction intermediate was calculated as $\Delta E_{\text {ads }}=E_{\text {adsorbate+surface }}-E_{\text {adsorbate }}-E_{\text {clean-surface. }}$. The activation energy $\left(\Delta E_{\mathrm{a}}\right)$ of a chemical reaction was defined as the energy difference between the initial and transition states, whereas the reaction energy $(\Delta E)$ was defined as the energy difference between the initial and final states. The enthalpy, entropy, and Gibbs free energy of each species were calculated by vibrational frequency analysis based on harmonic normal mode approximation using the finite difference method in VASP. The threshold for energy convergence for each iteration was set to $10^{-8} \mathrm{eV}$, and the forces on each atom were $0.01 \mathrm{eV} / \AA \AA$. The Gibbs free energy for a given species is $G(T, P)=E_{\mathrm{e}}+E_{\text {trans }}+E_{\text {rot }}+E_{\text {vib }}+P V-T\left(S_{\text {trans }}+S_{\text {rot }}+S_{\text {vib }}\right):$
where

$$
\begin{aligned}
E_{\text {trans }} & =\frac{3}{2} R T \\
E_{\text {rot }} & =R T \text { (for linear molecule) } \\
E_{\text {rot }} & =\frac{3}{2} R T \text { (for non-linear molecule) } \\
E_{\text {vib }} & =R \sum_{n} \frac{h v_{n}}{k_{\mathrm{B}}}\left(\frac{1}{2}+\frac{1}{e^{h v_{n} / k_{\mathrm{B}} T}-1}\right) \\
S_{\text {trans }} & =R\left(\ln q_{\text {trans }}+\frac{5}{2}\right), \text { where } q_{\text {trans }}=\left(\frac{2 \pi m k_{\mathrm{B}} T}{h^{2}}\right)^{3 / 2} \frac{k_{\mathrm{B}} T}{P} \\
S_{\text {rot }} & =R\left(\ln q_{\text {rot }}+1\right)(\text { for linear molecule }) \\
& \text { where } q_{\text {rot }}=\frac{1}{\sigma}\left(\frac{8 \pi^{2} k_{\mathrm{B}} T}{h^{2}}\right) \times I
\end{aligned}
$$

$$
\begin{aligned}
& S_{\mathrm{rot}}=R\left(\ln q_{\mathrm{rot}}+\frac{3}{2}\right)(\text { for nonlinear molecule }), \\
& \text { where } q_{\mathrm{rot}}=\frac{\sqrt{\pi}}{\sigma}\left(\frac{8 \pi^{2} k_{\mathrm{B}} T}{h^{2}}\right)^{3 / 2} \times \sqrt{I_{x} \times I_{y} \times I_{z}} \\
& S_{\mathrm{vib}}=R \sum_{n}\left(\frac{h v_{n} / k_{\mathrm{B}} T}{e^{h v_{n} / k_{\mathrm{B}} T}-1}-\ln \left(1-e^{-h v_{n} / k_{\mathrm{B}} T}\right)\right)
\end{aligned}
$$

where $I$ is the moment of inertia, $\sigma$ is the rotational symmetry number, and $m$ is the mass of the molecule. The translational, rotational, and vibrational enthalpic and entropic contributions of gas-phase molecules were calculated by considering them as ideal gases. For adsorbed molecules and transition states on the surface, the rotational and translational contributions were converted into vibration modes. We also approximated that the $P V$ term of the surface species is negligible because it is very small with regard to the energetic terms, and thus, we considered $G(T, P)=E_{\mathrm{e}}+E_{\text {vib }}-T \times S_{\text {vib }}$ in this case.

Acknowledgments: We thank J. Liu and Q. Xin for discussion on FTIR results. Funding: This work was supported by grants from the Dalian Institute of Chemical Physics (DICP) Fundamental Research Program for Clean Energy and Strategic Priority Research Program of the Chinese Academy of Sciences (grant no. XDB17020200), National Natural Science Foundation of China (grant no. 21621063), and DICP Fundamental Research Program for Clean Energy (DICP M201302). G.L. acknowledges financial support from The Netherlands Organization for Scientific Research (NWO) for her personal VENI grant (no. 016.Veni.172.034) and NWO SURFsara for providing access to supercomputer resources. Author contributions: C.L. proposed the project, supervised the research, and wrote and revised the manuscript. J.W. did the experiments and wrote the manuscript. G.L. performed the DFT calculations and drafted part of the manuscript. Z.L. reproduced part of the experiments. C.T. reproduced some catalyst preparation and reaction test. Z.F. and H.A. performed UV Raman spectroscopic characterizations. H.L. and T.L. performed analysis of some experimental and calculation results. All the authors participated in the discussion and agreed with the conclusions of the study. Competing interests: The authors declare that they have no competing interests. Data and materials availability: All data needed to support the conclusions in the paper are present in the paper and/or the Supplementary Materials. Additional data related to this paper may be requested from the authors.
