# A MATHEMATICAL PROGLEM RELATEO TO THE PHYSICAL THEORY OF LIQUID CRYSTAL CONFIGURATIONS 

Patricio Avizes and Yoshikazu Giga.

## 1. INTRODUCTION

The purpose of this note is to explain a mathematical problem in liquid crystal configuration and the mathematical tools that one is naturally lead to use in order to understand it.

It will turn out that one necessarily has to understand the structure of the set of singularities of functions of bounded variation. This was first studied by the fundamental work of DeGiorgi [161, [3] and H. Federer [7]. (see also Vol'pert [15], and Simon [12]. In this note we shall explain a different method that we have used in order to study this basic fact and which is useful to study the liquid crystal problem which we shall explain in Section 2. As a matter of fact we have recovered the well known results mentioned above and furthermore we have obtained new information that we shall be briefly discussing.

Our approach is motivated by the original work of De-Giorgi on the study of the set of singularities of a characteristic function of a set of finite perimeter, see [16] p.3-62 (see also Example (B) in Section 3.2). Roughly speaking we can say that we recover

De-Giorgi's ariginal argument and thereby we unified the theory on the structure of the set of smgularities for characteristic functions of sets of finite perimeter and general bounded variation functions.

One advantange of our approach is that it gives information on sets which are not necessarily rectiriable, like rank properties of Hessian measures, see Theorem $A$. This information is indeed essential to show the rectifiability of relevant sets, for instance the set of points where a function of bounded variation has jump discontinuities. Together with measure theorical arguments, see Section 3.3, this implies the descomposition. Let $u: \Omega \subseteq R^{n} \rightarrow R$ be g function of bounded variation, that is $u \varepsilon L^{1}(\Omega)$, Du (derivative in the distribution sense) is a finite Radon - measure. Then as measure

$$
D U=D U L S U D U L \Omega \backslash S
$$

where
(i) Du $\mathrm{L} \Omega \backslash 5$ is absolutely continuous with respect to the Lebesgue measure on $\mathbb{R}^{n}$ and the Lebesgue measure of $S$ is zero. Here DuL $S$ is the measure defined by (Du LS) (A) $=(D u)(A \cap S)$ for every Borel set in $R^{n}$;
(ii) $S$ can be descomposed in $S=E U L$ UN where
(a) $E$ is the set of jump discontinuity of $u$, that is
$E=\{x \varepsilon \Omega:$ ap lim sup $u>a p$ limini $u\}$
where
ap lime supt $=\sup \left\{\beta: 1 \mathrm{~m}\right.$ sup $\left.\int \quad x_{p}(y) d y f m^{n}>0\right)$ $x \quad r>0 \quad B_{\mu}(x)$
where $X_{\beta}=x_{\beta}, F_{\beta}=\{x \in \Omega: u(x) \geq \beta\}$ is the
characteristic unction of the set Similarly

$$
\text { ep } \lim _{x} \inf u=\inf \left\{p: \lim _{r \rightarrow 0} \sup _{S_{p}(x)}\left(1-x_{8}\right)(y) d y / r^{n}>0\right)
$$

Where $B_{r}(x)$ is the open ball of radius $r$ with center at $x$. Moreover: $E$ is (n-1) rectifiable, that is

$$
E=\bigcup_{j=1}^{\infty} F_{j} \cup W_{0} \quad \text { (disjoint union) }
$$

Where $\Gamma_{j}$ are compact sets contained in $c^{1}$ hypersurfaces and $H_{n-i}\left(N_{0}\right)=0$ where $H_{n-1}$ denotes the $(n-1)$-dimensional Hausdorff measure.
(b) In the set e u is approximately continuous, that is

$$
\text { ap } 1 \mathrm{~lm} \text { supu }=\text { ap } 1 \mathrm{im} \text { inf } u
$$

$x \quad x$
and if $H_{n-1}(A)<\infty$ then $|D u| L(E \cap A)=0$.
(c) $N$ is set of aero (n-i)-dimensional Hausdorff measure.

Current work suggests that our approach also gives important insight to relax the functional

$$
u \rightarrow \int_{\Omega}(u, \nabla u) d x
$$

for ue BV(Rm, Rmy where $f(v, p): ~ R m: B n m \rightarrow R$ and
(i) $f$ is continuous in $\psi_{,} f$ is convex in $p_{3}$
(ii) $\lim _{t \rightarrow \infty} \frac{f(v, t p)}{t}=f_{\infty}(\nu, p)$ exists
and it is bounded uniformly in $v$.

If $i$ is independent of $\gamma_{s} f(\nabla u)$ is defined as a measure Which is lower semicontinuous with respect to the weak star topology of measures and which can be approximated by smooth functions.

However, if if depends on $v$ the explicit definition of $f(u, \nabla u)$ for $u \& B V$ is mot in the literature except for the scalar case $(m=1)$ [5] or for special choice of $f$ when $n=1$. see [14].

We here suggest one definition at least when if is positive and homogeneous of degree one in $p$.

$$
\left(\left(u_{0} \nabla u\right)(A)=\int_{E \cap A} d i s t_{1}\left(u_{+,}, u_{-}\right) d H_{n-1}+f(u(x), h(x) \mid \nabla u / L(\Omega \backslash S)(A)\right.
$$

With

$$
\begin{aligned}
& \operatorname{dist}_{f}\left(u_{+}, u_{0}\right)= \operatorname{im} \quad \int_{0}^{1} f\left(\gamma(t)_{8} \sigma(0)\right) d t \\
& \gamma(0)=u_{+} \\
& \sigma(1)=u_{-}
\end{aligned}
$$

Where $u_{t}$ u are the trace of $u$ on $E$ from each side, $h(x)$ is the Radon-Nikodym derivative of $\bar{\nabla} u$ with respect to $|\nabla u|$, A is a Borel set in $\Omega$ and $\gamma$ is a $C$ curve that joins $u_{+}$with u. So far we have only checked that $f(u, \nabla u)$ is lower semicontinuous when $u$ is piecewise constant.

In a suitable form this relaxation problem is important in the liquid crystal problem which is explained in the next section.

## (2) THE LIQUID CRYSTAL PROBLEM, THE SMECTIC STATE.

In the theory of liquid crystal one has a domain $\Omega$ in $R^{3}$, the region occupied by the iiquid crystal and a unit vector field $u: \Omega \rightarrow 5^{2}$, called the optic axis. The alignment of this axis may be imfluenced by external magnetic or electric fields. In any case, there is associated a free energy density due to Ossen - Frank,

$$
\begin{gathered}
W(\nabla u, u)=k_{1}(d i v u)^{2}+k_{2}(u \cdot \operatorname{curlu})^{2}+k_{3} \mid \text { uscurlu }\left.\right|^{2} \\
*\left(k_{2}+k_{4}\right)\left(\operatorname{tr}(\nabla u)^{2}-(\text { div } u)^{2}\right)
\end{gathered}
$$

where the $k_{1}$ are constants with $k_{1}, k_{2}, k_{3}{ }^{2} 0_{0}$ One is interested in infima of the corresponding integral functionai subject to appropiate boundary conditions.

In the special case $k_{1}=k_{2}=k_{3}$ and $k_{4}=O_{1}$ W $W(\nabla, u)$ reduces to $|\nabla u|^{2}$ and critical points are harmonic maps from $\Omega$ to $S^{2}$. For energy minimizing harmonic maps from $\Omega$ to $s^{2}$ the singuiarities are at most isolated (schoen-Unlenbeck lloj) and there is good information on the asymptotic behavior near a singularity (L. Simon [13], Brezis-Coron-Lieb [2])

For the general $W$, Hardt-Kinderlehrer-Lin $[9]$ shows that singularities of the solutions have Hausdorf dimension less than one. Moreover, Brezis-Coron-Lieb [2] found restrictions on limit configurations of such singularities. In liquid crystal this state is known as nematic.

In any case, in the smectic state of liquid crystal one consider solutions of the form $u=\frac{\nabla \varphi}{|\nabla \varphi|}$ for some function $\varphi: \Omega \rightarrow R$ and the level surfaces of $p$ form a system of parallel surfaces

Experimentally, [11], one observes one dimensional singularities and the singularities lying in surfaces, which cannot be explained by the above theory (above, the singularities of the solution have Hausdorff dimension less that one). Simple examples and physical considerations (Ericksen [17] and Sethna [18]) suggest that the solution of the following pelaxition problem explain with acquiricy the phenomena.

We study the energy functional

$$
Q(u)=\int_{\Omega} \mid(|\nabla u|-1)^{2}+\varepsilon(\Delta u)^{2} d x
$$

Where $\Omega$ is now domain in $n, n \geq 2$.

It is clear that if $u$ minimizes 6 , then $u$ also minimizes
$\mathcal{I} u)=\varepsilon^{-1 / 2} G(u)$, We now consider the probiem

$$
\begin{aligned}
& \operatorname{Min} J_{\Sigma}(u)=J_{E}\left(\dot{u}_{\varepsilon}\right) \\
& u \& H^{2}(\Omega) \quad u_{\partial \Omega}=9 \quad \text { or }\left.\frac{\partial u}{\partial n}\right|_{\partial \Omega}=0 .
\end{aligned}
$$

It is a simple exercise to show that the minimum is achieved.
Heuristically we expect

$$
u_{\varepsilon} \rightarrow u_{0} \text { in } H^{1}(\Omega)
$$

$$
\left(u_{\varepsilon}\right)_{i j} \rightarrow\left(u_{0}\right)_{i j} \quad 1 \leq 1, j \leq m_{y} \text { weakly as measures, and }
$$

$\left|\nabla u_{0}\right|=1$, a.e. in $\Omega,\left(u_{0}\right)_{i j s} \quad 1 \leq i, j \leq n$ are fimite Radon
measures. When $n=3 u_{0}$ will ciescribe the phenomens of the smectic state of liquid crystal.

We notice at once that we can use the theory described in the introduction to study the structure of the set of singularities of $\nabla$ uo. For instance we can use it to study the following important question: What is the limiting energy? is this energy lower semicontinuous in the corresponding space?

To understand this question in more detalls we first observe that

$$
f_{\varepsilon}(u) \geq \int_{\Omega} 2| ||\nabla u|-1| | \Delta u \mid d x=E_{0}(u)
$$

It is therefore natural to conjecture that a suitable form of the energy $E_{0}$ will be the limiting energy. To formalize this, we first has to give meaning to E0fu) when $|\nabla u|=1 a_{0} e_{0}$ in $\Omega$, and $u_{i j}, I \leq 1, j \leq n_{s}$ are finite Redon measures. Briefly this goes as follows. By the Radon Nikodym theorem the singular part of the measure [D2u], the modulus of the largest eigenvalue of the symmetric matrix $\left[u_{i j}\right]$, has support in

$$
\sum=\left\{x \in \Omega^{:} \lim _{r \rightarrow 0} \frac{\left[D^{2} u\right](B r(x))}{r^{n}}=\infty\right\}
$$

and we may also assume that

$$
\lim _{r \rightarrow 0} \frac{u_{i j}\left(B_{r}(x)\right)}{\left[0^{2} u\right)\left(B_{r}(x)\right)}=A_{i j}(x), \lim _{r \rightarrow 0} \frac{\left|u_{i j}\right|\left(B_{r}(x)\right)}{\left|D^{2} u\right|\left(B_{r}(x)\right)}=\left|A_{i j}(x)\right|
$$

exist. Theorem $A$. Example $A$ in Section 3.2 and the measure theorical relations of Section 3.3 show that $\left(A_{i j}\right)$ has rank 1 on the set

$$
S=\left\{x \varepsilon \sum^{n} \infty>\lim _{f \rightarrow 0} \frac{\sup }{\left.\therefore D^{2} u\right]}=0\right\}
$$

and $S=\bigcup_{j=1}^{\infty} \Gamma_{j} \cup N_{0}$ (disjoint union) where $\Gamma_{j}$ are compact sets which are contained in $C^{1}$ hypersurtaces $C_{j}$ and $H_{n-1}\left(N_{0}\right)=0$.

The normal to $C_{i}$ on $\Gamma_{j}$ is the eigenvector of $A_{i j}$, it tums out. The proposal definition of $E_{9}$ is
$\frac{1}{2} E_{0}(u)=\sum_{0=1}^{\infty} \int_{\sum_{0}}^{\frac{\partial u}{\partial n^{t}}} \frac{\partial u}{\partial n^{-}} \quad\left|\sqrt{\tau^{2}+u^{2} \tan ^{-1}}\right| 0 \tau d H \quad{ }_{n-1}$
for $\nabla u B V(\Omega)$ and $|\nabla u|=1$ a.e. in .2. Here $\frac{\partial u}{\partial n-}<\frac{\partial u}{\partial n+}$ are the trace of $\nabla u$ on the normal direction of $c_{j}$ and $u_{t a n}$ denotes trace of $7 u$ in the tangential directions of $\mathrm{C}_{\mathrm{j}}$.

So far, we have only checked this definition is compatible with important cases. The studies mentioned in the introduction suggest that $E_{0}(u)$ is lower-semicontinuous in $M=\left\{u: \Omega \rightarrow R_{0}\right.$ $u_{j j}, i \leq i, j \leq n$ are finite Radon measures and $u^{k} \rightarrow u_{s} u^{k}, u$ \& $N$ if $\nabla u \rightarrow \nabla u$ in $L^{i}(\Omega)$.

To show that $J_{s} \rightarrow E_{0}$ the more natural thing to try is to prove that $J_{\varepsilon}$ converges to $E_{0}$ in the $\Gamma$-sense of De-Giorgi ([4], [141). To verify this, assuming that $E_{0}$ is lower semicontinuous in $\mathcal{M}_{\text {, }}$ it suffices to show that for $u \varepsilon \mathcal{M}^{( }$, there exists $u^{\varepsilon}$ in $H^{2}(\Omega), u^{\varepsilon} \rightarrow u$ in $M$ and $d_{\varepsilon}\left(u^{\varepsilon}\right) \rightarrow E_{0}(u)$ as $\varepsilon \rightarrow 0$. We believe that this is indeed true.
3. STNGULARTTIES OF FUNETION OF BOUNDED VARTTION AND RANK PROPERTIES OF HESSTAN MEASURES.

In this section we summarize the results that it will appear in 11.
3.1. Rank properties of Hessith Measuras. We work in the following seting. det u be a function defined in an open set $\Omega \in A^{n} n \geq 1$, whose sccond derivatives $u_{i j}, i \leq i_{i} j \leq n$ are fimite Radon - measures in $\Omega$. We are interested in the singular part of $u_{i j}$. Let

Where $\left[D^{2} u\right.$ ] is the modulus of the largest eigenvalue of the symmetric matrix $D^{2}{ }^{2}=\left(u_{i j}\right)$. By the Radon-Nikodym theorem, the singular part of $D^{2} u$ agrees with $D^{2} u$ Le. We may also assume (by taking off a set of $D^{2} u$ measure zero if necessary) that $x \in \Sigma$

$$
\lim _{r \rightarrow 0} \frac{u_{i j}\left(B_{r}(x)\right)}{\left[D^{2} u\right]\left(B_{r}(x)\right)}=A_{i j}(x) \text { exists }
$$

and

$$
\lim _{r \rightarrow 0} \frac{\left|u_{i j}\right|\left(B_{r}(x)\right)}{\left[D^{2} u\right]\left(B_{r}(x)\right)}=\left|A_{i j}(x)\right| \text { exists }
$$

Let now the upper density function be defined by

$$
\theta_{q}(x)=\lim _{r \rightarrow 0} \sup _{r \rightarrow} \frac{\left[0^{2} a\right]\left(B_{r}(x)\right)}{r^{q}}, n-1 \leq q<n .
$$

Theorem A. Let

$$
S_{q}=\left\{x \in \sum: \quad \infty \quad \theta_{q}^{*}(x)>0\right\} \quad n-1 \leq q<n_{0}
$$

Then on $s q,\left(A_{1 j}\right)$ has rank one.
Note: Exampies show that in general $S q$ is not rectifiable.

### 3.2. Blowing up and Rectilabilitg two eximples.

In this section we very briefly indicate that Theorem $A$, together with a blowing up argument and the Whitney criterium for rectifiability, 1161 p.53, can be used to show the rectifiability of two important sets.

Example $A$. Let $u: \Omega \subseteq \mathbb{R}^{n} \rightarrow R$ be a function such that:
(i) $H(\nabla u(x))=1$ a.c. in $\Omega$ where $H: R^{n} \rightarrow R$ is a convex runction:
(ii) $\mathrm{D}^{2} \mathrm{u}$ is a symmetric matrix of finite Radon measures. Define the lower $(n-1)$ density by

$$
\theta_{r}(x)=\liminf _{r \rightarrow 0} \frac{\left[D^{2} u\right]}{r n-1}\left(B_{r}(x)\right)
$$

Then $R_{1}=\left\{x \in E_{:} \infty=\theta(x)>0\right.$ is rectiliable. Mareover, the nomal vector for $x \in \mathcal{R}_{1}$ is given by the eigenvector of the matrix $D^{2} u(x)=\left(A_{11}(x)\right.$ in Theorem $A_{0}$

Example B. Let $A$ be a set of finite perimeter, that is the gradient (in the generalized sense) of the characteristic function of the set $A_{3} \forall X_{A,}$ is a ininite Racon measure, that is $\left|\nabla X_{A}\right|(\Omega)<\infty$. Let

$$
\begin{aligned}
\Sigma=\{x \in \Omega: & \lim _{r \rightarrow 0} \frac{\left|\nabla X_{A}\right|\left(B_{P}(x)\right)}{r}=\infty_{B} \\
& \left.\lim _{r \rightarrow 0} \frac{\nabla X_{A}(B r(x))}{\left|X_{A}\right|\left(B_{r}(x)\right)} \text { exists }\right\}
\end{aligned}
$$

and

$$
\theta_{k}(x)=\lim _{r \rightarrow 0} \inf \frac{\left|\nabla X_{A}\right|}{r^{n-1}}\left(B_{p}(x)\right)
$$

Then the set $R_{2}=\langle x \in \mathbb{E}: \infty>\theta(x)>0\rangle$ is rectifiable
In both examples the key idea of the proof is to use the rescaled measures:

$$
u_{i j}(K)=u_{i j}(x+t K) t 1-n_{8} \quad x \in R_{1}
$$

(in Example A) or

$$
\left(\nabla X_{A}\right)^{t}(K)=\nabla X_{A}(x+t K) t^{1-n_{s}} \quad x \in R_{2}
$$

(in Example B) where $K$ is an open set together with the Whitney criterium for rectifiability.
3.3 Relation Among several sets of singularities In this section we indicate that the results used in section 2 and De-Giorgi's descomposition of set of finite perimeter [15] p.3-62. follow from the resuits in Section 3.2 and the theorem below. Also, the descomposition of a general function of bounded variation (see introduction) follows from Theorem $A_{\text {, }}$ a blowing up argument (similar to the one explained in section 3.2 with the rescaled measures), the Whitney criterium for recifiability and the theorem below. Details of the proof can be found in [11.

Let $u: \Omega \rightarrow R$ be a function of bounded variation. By the Radion - Nikodym theorem, we may assume that
(3.1) $\lim _{r \rightarrow 0} \frac{\operatorname{Du}\left(B_{r}(x)\right)}{\mid \operatorname{Du}_{r}\left(B_{r}(x)\right)}=n(x)$ exists and $|n(x)|=1$
(We take off a set of |Du| measure zero, if neccessary) We recall for $x$ that satisfies (3.1)
(i) $e^{*}(x)=\lim _{r \rightarrow 0} \frac{|D u|\left(B_{r}(x)\right)}{r^{n-1}}$
(ii) $\theta_{x}(x)=\lim _{r \rightarrow 0} \frac{\operatorname{Du} \mid\left(B_{p}(x)\right)}{r^{n-1}}$ $x$ is a Lebesgue point of $u$ if there exists $c$ such that

$$
\lim _{r \rightarrow 0} \frac{1}{| | B_{r}(x) \mid} \int_{B_{r}(x)}|u(y)-c| d y=0
$$

We denote the set of Lebesgue points of $u$ by $\mathscr{L}$. By $E$ we denote the set of jump discontinuities (see introduction). Then we have the following result.

THEOREM $8(a)$ If $x \in \mathbb{L}_{,}$then $0(x)=0$
(b) If $x \in E$, then $\theta^{*}(x)=0$.
(c) $\mathscr{H}_{n-1}$ a.e. $x \in E_{y} \theta_{x}(x)=0$. Furthermore $\mathscr{H}_{n-1}$ a.e. $x \in E$ $\theta_{*}(x)=\theta^{*}(x)$,
(d) $\mathscr{H}_{n-1}$ a.e. if $x \in E$ then $x \in \mathscr{E}$.

Aknowledgement: The suthors would like to thank Bob Kohn for several stimulating conversations and for his encourgement and interest in the present work. The first author would also like to Shank Leon Simon for his invitation to visit the Australian National University and for his hospitality during the visit.
