#### Abstract

A new ZVCS resonant dc/dc converter is presented in which the resonant circuit is located at the secondary side of the transformer and using the secondary leakage inductance as the resonant inductor. The proposed converter topology is suitable for unregulated low-voltage to high-voltage power conversion, as in battery-powered systems. The MOSFET primary switches and the output rectifiers turn-on and turn-off operate under zero-voltage and zero-current switching conditions. The measured efficiency is moreover than $\mathbf{9 4 . 5 \%}$ from $\mathbf{2 0 \%}$ loaded to full loaded.

Index Terms-ZVCS, resonant converter, push-pull converter, step up converter.

## I. Introduction

A new ZVCS quasi-resonant dc/dc converter topology suitable for unregulated low-voltage to high-voltage conversion is presented. The converter acts as a dc-transformer in system where power from low-voltage source, typically batteries, albeit stiff, higher intermediate voltage for use by a subsequent converter stage [1].

The LCL-resonant dc/dc converter push-pull topology [1] operate under zero-voltage switching condition where the input currents can exceed input voltage by an order of magnitude with high-efficiency.
Since the output load of the LCL topology is series connected with the output resonant inductor, so the output current will swing corresponding to the resonant current, and it is difficult to decrease or control the ripple output voltage.

In this paper, we proposed the ZVCS resonant push-pull $\mathrm{dc} / \mathrm{dc}$ converter with low ripple output voltage.

## II. Circuit Description

The proposed dc/dc converter is based on push-pull dc/dc converter and it consists of MOSFET primary switches ( $\mathrm{S}_{1}, \mathrm{~S}_{2}$ ), series resonant circuit (L-C), output rectifier $\left(\mathrm{D}_{1}-\mathrm{D}_{4}\right)$, output capacitor $\left(\mathrm{C}_{\mathrm{O}}\right)$ and output load $\left(\mathrm{R}_{\mathrm{L}}\right)$. The shunt capacitors $\left(\mathrm{C}_{\mathrm{S} 1}, \mathrm{C}_{\mathrm{S} 2}\right)$ are the inherent drain-source capacitance of the MOSFET switches, and the series inductor ( L ) is the
leakage-inductance of the secondary side of the high-frequency transformer. The resonant circuit (L-C) resonates at the switching frequency of $S_{1}$ and $S_{2}$.

## III. Circuit Operation

The primary switches $\left(S_{1}, S_{2}\right)$ are driven by the fixed frequency pulses at duty ratio below $50 \%$; out of phase. The circuit operation modes are shown in fig. 2 and the idealized operating waveforms are shown in fig.3. The quality factor of the resonant circuit (L-C) have to low enough to keep the resonant current $\left(i_{r}\right)$ is discontinuous.
Mode 1: S 1 is driven by $v_{g 1}$ to conduct the transformer primary current $i_{1}$ at the zero-voltage condition, and $\mathrm{S}_{1}$ is turned-off at zero current due by the resonant circuit (L-C) at the secondary side.
Mode 2: Both switches are turned-off and the shunt capacitor $\mathrm{C}_{\mathrm{S} 1}$ will be charged until its voltage reached to $2 \mathrm{~V}_{\text {in }}$ by the remain transformer magnetizing current, in the same time $\mathrm{C}_{\mathrm{S} 2}$ will be discharged from $2 \mathrm{~V}_{\text {in }}$ to zero volt.
Mode 3: $\mathrm{S}_{2}$ is driven by $v_{g 2}$ to conduct the transformer primary current $i_{2}$ at the zero-voltage condition, and $\mathrm{S}_{2}$ is turned-off at zero current due by the resonant circuit (L-C) at the secondary side.

Fig. 2. Converter operations
Mode 4: Both switches are turned-off and the shunt capacitor $\mathrm{C}_{\mathrm{S} 2}$ will be charged until its voltage reached to $2 \mathrm{~V}_{\mathrm{in}}$ by the remain transformer magnetizing current, in the same time $\mathrm{C}_{\mathrm{S} 1}$ will be discharged from $2 \mathrm{~V}_{\text {in }}$ to zero volt.
The time duration of mode 2 and 4 are depended on the inherent drain-source capacitances of the switches and the transformer magnetizing current of the transformer.

## IV. EXPERIMENTAL RESULTS

In experimentation, a 12 V input 130 W prototype converter shown in fig. 4 was built and tested. The ferrite core TDK PQ3220-PC44 with primary windings $\mathrm{Np} 1=\mathrm{Np} 2=2$ turns $(0.6 \mathrm{~mm} * 3$ lines) and secondary winding $\mathrm{Ns}=36$ turns $(0.6 \mathrm{~mm} * 2$ lines) was used as the transformer, the secondary lumped model is shown in fig. 5. We use the MOSFET IRL2505S $\left(\mathrm{R}_{\mathrm{ds}}\right.$ on=0.008 $\left.\Omega\right)$ as the primary switches, rectifier

Fig. 3. Idealized operating waveforms
diodes RPG10B*4 as the output rectifier, 221.67 nF as the resonant capacitor (C) and 3.3 uF as the output capacitor.The converter switching frequency was calculated from the resonant frequency of L-C circuit. From fig.5, the measured secondary leakage inductance of the transformer $\mathrm{L}=58.11 \mathrm{uH}$, so the resonant frequency is equal 44.34 kHz . Figure 6 shows the experimental converter voltages and current waveforms when loaded by $250 \Omega$ resistor at $\mathrm{V}_{\text {out }}=188.3 \mathrm{~V}$. The switching frequency $\left(f_{S}\right)$ was fixed at 44 kHz and both of $v_{g 1}$ and $v_{g 2}$ duty ratios are equal to $48.5 \%$. Figure 6(b) shows the zero-voltage-zero-current (ZVCS) turn-on and turn-off switching of the primary switches, and shows the time durations of mode 2 and 4 . Figure 7 shows the conversion efficiency versus output power. The conversion efficiency can be maintained over $94.5 \%$ when supply load 22.2 to 138.5 watt. Figure 8 shows the output voltage loading effect when the output current is increased from 0.11 A to 0.74 A .

Figure 9 shows the relation of output voltage and the conversion efficiency when the switching frequency was varied and output load was fixed at $250 \Omega$.

## V. CONCLUSION

A new ZVCS quasi-resonant dc/dc converter topology can operates at high-conversion efficiency and very low switching noise [2] with simple operation and low cost. It is ideally suited for unregulated dc/dc conversion from low-voltage high-current source.

Since it uses the secondary leakage inductance as the resonant element and the converter needs no high Q resonant circuit, so the discrete resonant inductor is not required. Moreover, it easily to control the output ripple voltage because most of resonant current flow through the output capacitor.
