

A Note on Elliptic Curves Over Finite Fields

By Hans-Georg Rück

Abstract. Let E be an elliptic curve over a finite field k and let $E(k)$ be the group of k -rational points on E . We evaluate all the possible groups $E(k)$ where E runs through all the elliptic curves over a given fixed finite field k .

Let k be a finite field with $q = p^n$ elements. An elliptic curve E over k is a projective nonsingular curve given by an equation

$$(1) \quad Y^2Z + a_1XYZ + a_3YZ^2 = X^3 + a_2X^2Z + a_4XZ^2 + a_6Z^3$$

with coefficients a_1, \dots, a_6 in k . For each field \bar{k} that contains k , the set $E(\bar{k})$ of points with coordinates in \bar{k} satisfying (1) forms an Abelian group whose zero element can be chosen as the element $(0, 1, 0)$. In this note we want to look at the following Question 1: Given a fixed finite field k , what are the possible Abelian groups $E(k)$, when the coefficients of the equation (1) vary over all the possible values in k ? The answer to this question is given in Theorem 3. If we just look at the possible orders $\#E(k)$, the appropriate Question 2 was answered by Waterhouse [4] (see also Deuring [1] for $k = \mathbb{F}_p$) using the theorem of Honda and Tate [3] for Abelian varieties over finite fields.

THEOREM 1a [4]. *All the possible orders* $h = \#E(k)$ are given by $h = 1 + q - \beta$, where β is an integer with $|\beta| \leq 2\sqrt{q}$ satisfying one of the following conditions:*

- (a) $(\beta, p) = 1$;
- (b) *If n is even:* $\beta = \pm 2\sqrt{q}$;
- (c) *If n is even and $p \not\equiv 1 \pmod{3}$:* $\beta = \pm \sqrt{q}$;
- (d) *If n is odd and $p = 2$ or 3 :* $\beta = \pm p^{(n+1)/2}$;
- (e) *If either (i) n is odd or (ii) n is even, and $p \not\equiv 1 \pmod{4}$:* $\beta = 0$.

Following the general ideas of Waterhouse [4] we can also give an answer to the first question.

For an elliptic curve E over k let $\text{End}(E)$ be the ring of group endomorphisms of E which are given by algebraic equations with coefficients in k . It is known that $\text{End}(E)$ is an order in a finite-dimensional division algebra over \mathbb{Q} . This division algebra determines $\#E(k)$:

THEOREM 2 [2]. *Let E, E' be elliptic curves over k ; then*

$$\#E(k) = \#E'(k) \quad \text{if and only if} \quad \text{End}(E) \otimes_{\mathbb{Z}} \mathbb{Q} = \text{End}(E') \otimes_{\mathbb{Z}} \mathbb{Q}.$$

There is a special endomorphism π , called the Frobenius endomorphism, which maps a point $P = (x, y, z)$ on E to $\pi(P) = (x^q, y^q, z^q)$ on E . From this definition it follows immediately that $E(k)$ is the set of all the points P on E with $\pi(P) = P$.

If h is a fixed possible order $\#E(k)$, then by Theorem 2 the division algebra $K = \text{End}(E) \otimes_{\mathbf{Z}} \mathbf{Q}$ is fixed. What are the orders in K that are rings of endomorphisms of elliptic curves over k ? The answer is:

THEOREM 1b [4]. *Let $h = 1 + q - \beta$ be a possible order $\#E(k)$, where β satisfies one of the conditions (a), ..., (e) of Theorem 1a.*

In case (a): $K = \mathbf{Q}(\pi)$ is an imaginary quadratic field over \mathbf{Q} ; all the orders in K are possible endomorphism rings.

In case (b): K is a division algebra of order 4 with center \mathbf{Q} , π is a rational integer, all the maximal orders in K are possible endomorphism rings.

In cases (c), (d), (e): $K = \mathbf{Q}(\pi)$ is an imaginary quadratic field over \mathbf{Q} , all the orders in K whose conductor is prime to p are possible endomorphism rings.

Let h be a possible order and $h = \prod_l l^{h_l}$ its decomposition in powers of prime numbers. Since the genus of an elliptic function field is one, the possible $E(k)$ with $\#E(k) = h$ are among all the groups of the form

$$\mathbf{Z}/p^{h_p}\mathbf{Z} \times \prod_{l \neq p} (\mathbf{Z}/l^{a_l}\mathbf{Z} \times \mathbf{Z}/l^{h_l - a_l}\mathbf{Z}) \quad \text{with } 0 \leq a_l \leq h_l.$$

The relation between $\text{End}(E)$ and the structure of $E(k)$ is given by the following lemma:

LEMMA 1. *Let m be a positive integer which is not divisible by p , and let E_m be the group of the points P on E with $mP = 0$. Then E_m is contained in $E(k)$ if and only if $\pi - 1$ is divisible by m in $\text{End}(E)$.*

Proof. If $\pi - 1$ is divisible by m in $\text{End}(E)$, then $\pi - 1 = \lambda \cdot m$ with $\lambda \in \text{End}(E)$. Let $P \in E_m$, then $(\pi - 1)(P) = \lambda \cdot m(P) = 0$. Hence $\pi(P) = P$ and $E_m \subset E(k)$.

If $E_m \subset E(k)$, then the kernel of $\pi - 1$ contains the kernel of the multiplication by m . Since the multiplication by m is separable, the universal mapping property for Abelian varieties (see [5, p. 27, Proposition 10]) shows that $\pi - 1 = m \cdot \lambda$ with $\lambda \in \text{End}(E)$.

LEMMA 2. *We assume that π is not contained in \mathbf{Q} ; then by Theorem 1b the division algebra K is an imaginary quadratic field. The maximal order in K is denoted by O_K . Let l be a rational prime number which is different from p and suppose that $\pi - 1 = l^x \cdot \omega$, where $\omega \in O_K$ is not divisible by l . Then*

$$(2) \quad x = \min \left\{ v_l(q - 1), \left\lceil \frac{v_l(\#E(k))}{2} \right\rceil \right\}.$$

($\lceil \lambda \rceil$ is the largest rational integer $\leq \lambda$; $v_l(\cdot)$ is the normalized valuation of \mathbf{Z} corresponding to l .)

Proof. The zeta function of E yields the equation

$$\#E(k) = (\pi - 1)(\bar{\pi} - 1) = q - (\pi + \bar{\pi}) + 1.$$

From this we get the two equations

$$(3) \quad \#E(k) = l^{2x} \cdot \omega \cdot \bar{\omega}$$

and

$$(4) \quad \#E(k) = (q - 1) - (\pi - 1) - (\bar{\pi} - 1).$$

If l is prime to ω , then (3) yields $2x = v_l(\#E(k))$ and (4) yields

$$v_l(q - 1) \geq \min\{x, v_l(\#E(k))\} \geq \left\lfloor \frac{v_l(\#E(k))}{2} \right\rfloor.$$

This proves (2). If l is not prime to ω , then either l is decomposed or is ramified in O_K . Suppose $(l) = \mathcal{L} \cdot \bar{\mathcal{L}}$ in O_K with $\mathcal{L} \neq \bar{\mathcal{L}}$. Let, for example, $v_{\mathcal{L}}(\omega) > 0$. Then $v_{\bar{\mathcal{L}}}(\omega) = 0$ and $v_{\mathcal{L}}(\omega + \bar{\omega}) = 0$. Equation (3) yields $2x < v_l(\#E(k))$ and Eq. (4) yields $x \geq \min\{v_l(\#E(k)), v_l(q - 1)\}$, where equality holds if $v_l(\#E(k))$ and $v_l(q - 1)$ are different. A detailed examination of the possible values of $v_l(\#E(k))$ and $v_l(q - 1)$ shows that (2) holds. Suppose $(l) = \mathcal{L}^2$ in O_K . If $v_{\mathcal{L}}(\omega) > 0$, then $v_{\mathcal{L}}(\omega) = 1$. Equation (3) yields $2x + 1 = v_l(\#E(k))$. Thus we get

$$x = \frac{v_l(\#E(k)) - 1}{2} = \left\lfloor \frac{v_l(\#E(k))}{2} \right\rfloor.$$

Equation (4) shows that $v_l(q - 1) \geq [v_l(\#E(k))/2]$, which proves (2).

We can now give an answer to the first question and prove the following theorem.

THEOREM 3. *Let k be a finite field with $q = p^n$ elements. Let $h = \prod l^{h_l}$ be a possible order $\#E(k)$ of an elliptic curve E over k . Then all the possible groups $E(k)$ with $\#E(k) = h$ are the following:*

$$\mathbf{Z}/p^{h_p}\mathbf{Z} \times \prod_{l \neq p} (\mathbf{Z}/l^{a_l}\mathbf{Z} \times \mathbf{Z}/l^{h_l - a_l}\mathbf{Z})$$

with

- (a) In case (b) of Theorem 1a: Each a_l is equal to $h_l/2$;
- (b) In cases (a), (c), (d), (e) of Theorem 1a: a_l is an arbitrary integer satisfying $0 \leq a_l \leq \min\{v_l(q - 1), [h_l/2]\}$.

Proof. (a) In case (b) of Theorem 1a we get $\pi \in \mathbf{Z}$ and $h = (\pi - 1)^2$. Furthermore, $\pi - 1$ is divisible by m in $\text{End}(E)$ if and only if $\pi - 1$ is divisible by m in \mathbf{Z} . Hence Lemma 1 shows that $a_l = \min\{v_l(\pi - 1), [h_l/2]\} = h_l/2$.

(b) Let $\{1, \eta\}$ be an integral basis of O_K . Then $\pi = a + b\eta$ with $a, b \in \mathbf{Z}$ and $b \neq 0$. This yields $\pi - 1 = a - 1 + b\eta$ with

$$\min\{v_l(a - 1), v_l(b)\} = \min\{v_l(q - 1), [h_l/2]\}$$

by Lemma 2. For each $l \neq p$ let a_l be arbitrary with

$$0 \leq a_l \leq \min\{v_l(q - 1), [h_l/2]\}.$$

Consider the order R in O_K whose conductor is equal to $\prod_{l \neq p} l^{v_l(b) - a_l}$. There is an elliptic curve E over k with $R = \text{End}(E)$ by Theorem 1b. The exact l -power that divides $\pi - 1$ in R is equal to l^{a_l} for each $l \neq p$. Hence Lemma 1 shows that $E(k)$ is equal to $\mathbf{Z}/p^{h_p}\mathbf{Z} \times \prod_{l \neq p} (\mathbf{Z}/l^{a_l}\mathbf{Z} \times \mathbf{Z}/l^{h_l - a_l}\mathbf{Z})$.
