# A survey and some generalizations of Bessel processes 

ANJA GÖING-JAESCHKE ${ }^{1}$ and MARC YOR ${ }^{2}$<br>${ }^{1}$ Baloise Insurance Group, Aeschengraben 21, CH-4002 Basel, Switzerland.<br>E-mail: anja.goeing-jaeschke@baloise.ch<br>${ }^{2}$ Université Pierre et Marie Curie, Laboratoire de Probabilités, 4 Place Jussieu, F-75252 Paris Cedex 05, France

Bessel processes play an important role in financial mathematics because of their strong relation to financial models such as geometric Brownian motion or Cox-Ingersoll-Ross processes. We are interested in the first time that Bessel processes and, more generally, radial Ornstein-Uhlenbeck processes hit a given barrier. We give explicit expressions of the Laplace transforms of first hitting times by (squared) radial Ornstein-Uhlenbeck processes, that is, Cox-Ingersoll-Ross processes. As a natural extension we study squared Bessel processes and squared Ornstein-Uhlenbeck processes with negative dimensions or negative starting points and derive their properties.

Keywords: first hitting times; Cox-Ingersoll-Ross processes; Bessel processes; radial OrnsteinUhlenbeck processes; Bessel processes with negative dimension

## 1. Introduction

Bessel processes have come to play a distinguished role in financial mathematics for at least two reasons, which have a lot to do with the diffusion models usually considered. One of these models is the Cox-Ingersoll-Ross (CIR) family of diffusions, also known as squareroot diffusions, which solve

$$
\begin{equation*}
\mathrm{d} X_{t}=\left(a+b X_{t}\right) \mathrm{d} t+c \sqrt{\left|X_{t}\right|} \mathrm{d} B_{t} \tag{1}
\end{equation*}
$$

where $X_{0}=x_{0} \geqslant 0, a \geqslant 0, b \in \mathbb{R}, c>0$ and $\left(B_{t}\right)$ is standard Brownian motion. For every given value $x_{0} \geqslant 0$, equation (1) admits a unique solution; this solution is strong, that is, adapted with respect to the natural filtration of $\left(B_{t}\right)$, and takes values in $[0, \infty)$. If $a=0$ and $x_{0}=0$, the solution of (1) is $X_{t} \equiv 0$, and from the comparison theorem for one-dimensional diffusion processes (Revuz and Yor 1999, Chapter IX, Theorem (3.7)) we deduce $X_{t} \geqslant 0$ for $a \geqslant 0, x_{0} \geqslant 0$. Hence, in this case, the absolute value in (1) may be omitted a posteriori. Cox et al. (1985) proposed this family of diffusions for modelling short-term interest rates. In recent financial literature they are often studied from different points of view, or serve as important reference processes; see, for instance, Chen and Scott (1992), Deelstra and Parker (1995), Delbaen (1993), Duffie and Singleton (1995), Frydman (1994) and Leblanc (1996; 1997). They are also used for modelling stochastic volatility; see, for example, Ball (1993),

Genotte and Marsh (1993) and Heston (1993). The other even more fundamental model is geometric Brownian motion,

$$
\begin{equation*}
S_{t}=S_{0} \exp \left(v t+\sigma B_{t}\right) \tag{2}
\end{equation*}
$$

where $v, \sigma \in \mathbb{R}$, used as a standard model for stock prices. In both cases, $X$ and $S$ can be represented in terms of (squares of) Bessel processes. We recall the definition of (squares of) Bessel processes (Revuz and Yor 1999, Chapter XI).

Definition 1. For every $\delta \geqslant 0$ and $x_{0} \geqslant 0$, the unique strong solution to the equation

$$
\begin{equation*}
X_{t}=x_{0}+\delta t+2 \int_{0}^{t} \sqrt{\left|X_{s}\right|} \mathrm{d} B_{s} \tag{3}
\end{equation*}
$$

is called the square of $a \delta$-dimensional Bessel process starting at $x_{0}$ and is denoted by $\mathrm{BESQ}_{x_{0}}^{\delta}$.

Clearly (3) is a particular case of (1), with $a=\delta, b=0, c=2$. We call the number $\delta$ the dimension of $\mathrm{BESQ}^{\delta}$. This terminology arises from the fact that, in the case $\delta \in \mathbb{N}$, a $\mathrm{BESQ}^{\delta}$ process $X_{t}$ can be represented by the square of the Euclidean norm of $\delta$ dimensional Brownian motion $B_{t}: X_{t}=\left|B_{t}\right|^{2}$. The number $v \equiv \delta / 2-1$ is called the index of the process $\mathrm{BESQ}^{\delta}$. For $\delta \geqslant 2, \mathrm{BESQ}^{\delta}$ processes will never reach 0 for $t>0$, and for $0 \leqslant \delta<2$ they reach 0 almost surely.

Definition 2. The square root of $\mathrm{BESQ}_{y^{2}}^{\delta}, \delta \geqslant 0, y \geqslant 0$, is called the Bessel process of dimension $\delta$ starting at $y$ and is denoted by $\mathrm{BES}_{y}^{\delta}$.

For extensive studies on Bessel processes we refer to Revuz and Yor (1999) and Pitman and Yor (1980; 1982a); see also Appendix A.

We now show how a general CIR process (1) may be represented in terms of a BESQ process. The relation

$$
\begin{equation*}
X_{t}=\mathrm{e}^{b t} Y\left(\frac{c^{2}}{4 b}\left(1-\mathrm{e}^{-b t}\right)\right) \tag{4}
\end{equation*}
$$

where $Y$ denotes a squared Bessel process with dimension $\delta=4 a / c^{2}$, clearly establishes a correspondence between the two families of processes. We remark that this relation is used in, for example, Delbaen and Shirakawa (2003), Shirakawa (2003) and Szatzschneider (1997). For geometric Brownian motion (2), the Lamperti relation holds

$$
\begin{equation*}
S_{t}=\rho^{\left(v / \sigma^{2}\right)}\left(\sigma^{2} \int_{0}^{t} S_{s}^{2} \mathrm{~d} s\right), \quad t \geqslant 0 \tag{5}
\end{equation*}
$$

where $\left(\rho^{\left(v / \sigma^{2}\right)}(u), u \geqslant 0\right)$ denotes a Bessel process with index $v / \sigma^{2}$, with $\rho^{\left(v / \sigma^{2}\right)}(0)=S_{0}$; see Lamperti (1972) and Williams (1974). The Lamperti representation (5) has been very useful in connection with, for example, Asian option pricing; see Geman and Yor (1993) and Yor (1992a, Chapter 6). For a multivariate extension of the Lamperti relation we refer to Jacobsen (2001). It may be helpful to indicate that $A_{t}=\sigma^{2} \int_{0}^{t} S_{s}^{2}$ ds admits as its inverse process

$$
u \rightarrow \int_{0}^{u} \frac{\mathrm{~d} h}{\sigma^{2}\left(\rho_{h}^{\left(v / \sigma^{2}\right)}\right)^{2}}
$$

We now make some remarks about the range of the values of the parameters $a, b, c, \sigma$ and $v$ which appear in (1)-(5). The signs of $c$ and $\sigma$ are irrelevant since $B \stackrel{(\mathrm{~d})}{=}-B$. We assume $c, \sigma>0$. In fact, by scaling we may and will restrict ourselves to $c=2$ and $\sigma=1$. For $c=2$, CIR processes defined by (1) coincide with squared radial Ornstein-Uhlenbeck processes which are studied in detail in Section 2 (see (7)), and in the following we will use the two terms interchangeably. The sign of $b$ influences the behaviour of a CIR process $X$, since in the case $a>0$ there exists a unique stationary density of $X$ only if $b<0$; we note that stationary CIR processes also enjoy the ergodic property. In the case $a \geqslant c^{2} / 2=2$, a CIR process starting at $x_{0} \geqslant 0$ stays strictly positive for $t>0$; for $a<2$, a CIR process $X_{t}$ starting at $x_{0} \geqslant 0$ hits 0 with probability $\left.p \in\right] 0$, $1[$ if $b>0$ and almost surely if $b \leqslant 0$. Note that in the case $a>0$ the boundary 0 is instantaneously reflecting, whereas in the case $a=0$, when a CIR process $X_{t}$ hits 0 it is extinct, i.e. it remains at 0 .

Studies of square-root diffusions defined by (1) have hitherto always assumed $a \geqslant 0$ and $x_{0} \geqslant 0$. Under these assumptions, we have seen how to deduce $X_{t} \geqslant 0$ for all $t \geqslant 0$ from the comparison theorem for one-dimensional diffusion processes and the absolute value in the square-root term can be omitted. But it also seems natural to consider $a<0$ or to start the process at $x_{0}<0$. In such cases one should be careful about the formulation of the square-root term; for the rest of this section we consider the case $a<0$ and $x_{0}>0$ with the formulation (1). But see also Section 3 for a more general substitution: we replace $\sigma(x) \equiv c \sqrt{|x|}$ by $\tilde{\sigma}(x) \equiv c \sqrt{\alpha x^{+}+\beta x^{-}}, \alpha, \beta \geqslant 0$. The process $\left(X_{t}\right), t \geqslant 0$, defined by (1) with $a<0, \quad b \in \mathbb{R}, \quad c>0$ and starting at $x_{0}>0$ remains in $\mathbb{R}_{+}$until $T_{0}=$ $\inf \left\{t>0 \mid X_{t}=0\right\}$. Then, since $Y_{t} \equiv-X_{T_{0}+t}$ satisfies

$$
\mathrm{d} Y_{t}=\left(-a-b Y_{t}\right) \mathrm{d} t+c \sqrt{\left|Y_{t}\right|} \mathrm{d} \tilde{B}_{t},
$$

we know that $Y_{t} \geqslant 0$ for all $t \geqslant 0$, thus ( $X_{t}, t \geqslant T_{0}$ ) takes values in $\mathbb{R}_{-}$and $\left(Y_{t}\right)$ is a CIR process (1) with parameters $-a>0,-b \in \mathbb{R}$ and $c>0$.

Consider formula (5) with $v<0$. We know from Dufresne (1990) - see also Pollack and Siegmund (1985) and Yor (1992b), Théorème 1) - that

$$
\int_{0}^{\infty} \exp 2\left(B_{s}+v s\right) \mathrm{d} s \stackrel{(\mathrm{~d})}{=} \frac{1}{2 Z_{(-v)}},
$$

where $Z_{\mu}, \mu>0$, is a gamma variable with index $\mu$, that is,

$$
P\left(Z_{\mu} \in \mathrm{d} t\right)=\frac{t^{\mu-1} \mathrm{e}^{-t}}{\Gamma(\mu)} \mathrm{d} t
$$

Since $S_{t} \rightarrow 0$ as $t \rightarrow \infty$, then $\rho_{u}^{(\nu)} \rightarrow 0$ as $u$ converges to $\int_{0}^{\infty} \exp 2\left(B_{s}+v s\right) \mathrm{d} s$, and $\tilde{T}_{0} \equiv \inf \left\{t \mid \rho_{t}^{(\nu)}=0\right\}=\int_{0}^{\infty} \exp 2\left(B_{s}+v s\right) \mathrm{d} s$. It seems natural to consider $\left(\rho_{\tilde{T}_{0}+u}, u \geqslant 0\right)$. The case $v<-1$ corresponds to a Bessel process $\rho^{(v)}$ with dimension $\delta=2(v+1)<0$. In Section 3 we will derive and discuss properties of negative-dimensional squared Bessel
processes, and also squared radial Ornstein-Uhlenbeck processes with $\delta<0$, with starting points in $\mathbb{R}$.

The above discussion shows how first hitting times of squared radial Ornstein-Uhlenbeck processes (CIR processes) may arise. In Section 2, we present a survey of the explicit computations of the Laplace transform of first hitting times of (squared) radial OrnsteinUhlenbeck processes, by exploiting the relation between radial Ornstein-Uhlenbeck processes and Bessel processes. Note that because of the previous discussion on the sign and behaviour of $X$ in the negative-dimensional case we will have no difficulty in computing the Laplace transforms of first hitting times $T_{y}$ of a negative-dimensional process $X$ starting at $x_{0}$ in all possible cases, say $x_{0}>0>y$.

From a financial point of view we are interested in the quantity

$$
\mathrm{E}_{a}\left[1_{\left(T_{x}<t\right)}\left(R_{t}-k\right)^{+}\right],
$$

with a radial Ornstein-Uhlenbeck process $\left(R_{t}\right)$ starting at $a \geqslant 0$ (see Section 2) and $k \in \mathbb{R}^{+}$. We remark that the quantity $\mathrm{E}\left[1_{\left(T_{r}<t\right)}\left(S_{t}-k\right)^{+}\right]$, expressing values of barrier options with underlying stock price process $\left(S_{t}\right)$ as in (2), is investigated in Chesney et al. (1997) by considering Laplace transforms with respect to time. The Laplace transform of $\mathrm{E}_{a}\left[1_{\left(T_{x}<t\right)}\left(R_{t}-k\right)^{+}\right]$with respect to time is

$$
\begin{aligned}
\int_{0}^{\infty} \mathrm{e}^{-\alpha t} \mathrm{E}_{a}\left[1_{\left(T_{x}<t\right)}\left(R_{t}-k\right)^{+}\right] \mathrm{d} t & =\mathrm{E}_{a}\left[\int_{T_{x}}^{\infty} \mathrm{e}^{-\alpha t}\left(R_{t}-k\right)^{+} \mathrm{d} t\right] \\
& =\mathrm{E}_{a}\left[\mathrm{e}^{-\alpha T_{x}} \int_{0}^{\infty} \mathrm{e}^{-\alpha u}\left(R_{T_{x}+u}-k\right)^{+} \mathrm{d} u\right] .
\end{aligned}
$$

Using the strong Markov property, this equals

$$
\begin{equation*}
\mathrm{E}_{a}\left[\mathrm{e}^{-\alpha T_{x}}\right] \mathrm{E}_{x}\left[\int_{0}^{\infty} \mathrm{e}^{-\alpha u}\left(R_{u}-k\right)^{+} \mathrm{d} u\right], \tag{6}
\end{equation*}
$$

which gives a clear motivation for our computations below of the Laplace transforms of first hitting times of radial Ornstein-Uhlenbeck processes, as well as that of their resolvents, here applied to the function $r \rightarrow(r-k)^{+}$; as for the resolvent, we refer to Remark 6 in Section 2.

To conclude this section, we should mention that we have preferred, in this paper, the use of stochastic arguments, i.e. Itô's formula, Doob's $h$-transform, time reversal, etc. to that of differential equations arguments which nonetheless play an important role throughout.

## 2. First hitting times of radial Ornstein-Uhlenbeck processes

As indicated in the introduction, we are interested in the law of first hitting times of (squared) radial Ornstein-Uhlenbeck processes. For general discussions of first hitting times of diffusions, we refer to Arbib (1965), Breiman (1967), Horowitz (1985), Kent (1978a), Nobile et al. (1985), Novikov (1981; 1983; 1994), Pitman and Yor (1999; 2003), Ricciardi and Sato (1988), Rogers (1981), Salminen (1988), Shepp (1967), Siegert (1951), Truman
and Williams (1990) and Yor (1984). More general discussions of inverse local times and occupation times $\int_{0}^{T} 1_{\left(X_{s} \leqslant y\right)} \mathrm{d} s$, when $X$ is a diffusion and $T$ a particular stopping time, are dealt with in Hawkes and Truman (1991), Truman (1994) and Truman et al. (1995), with particular emphasis on the Ornstein-Uhlenbeck case.

First we recall the definition of (squared) radial Ornstein-Uhlenbeck processes. We will use different notation than in (1) which is related to the notation in Definition 1. Let ( $W_{t}$ ) be a one-dimensional Brownian motion, $\lambda \in \mathbb{R}, \delta \geqslant 0$ and $z \geqslant 0$. The solution to the equation

$$
\begin{equation*}
Z_{t}=z+\int_{0}^{t}\left(\delta-2 \lambda Z_{s}\right) \mathrm{d} s+2 \int_{0}^{t} \sqrt{\left|Z_{s}\right|} \mathrm{d} W_{s} \tag{7}
\end{equation*}
$$

is unique and strong (Revuz and Yor 1999, Chapter IX, $\S 3$ ); as in the discussion of equation (1), we deduce $Z_{t} \geqslant 0$. This process is called a squared $\delta$-dimensional radial OrnsteinUhlenbeck process with parameter $-\lambda$ and its law on $C\left(\mathbb{R}_{+}, \mathbb{R}\right)$ is denoted by ${ }^{-\lambda} Q_{z}^{\delta}$. It is a Markov process; hence, the square root of this process is also a Markov process and is called a $\delta$-dimensional radial Ornstein-Uhlenbeck process with parameter $-\lambda$. Denote its law on $C\left(\mathbb{R}_{+}, \mathbb{R}\right)$ by ${ }^{-\lambda} P_{x}^{\delta}$ where $x=\sqrt{z}$. The following application of Girsanov's theorem relates ${ }^{-\lambda} P_{x}^{\delta}$ to $P_{x}^{\delta}$, the law of a $\operatorname{BES}^{\delta}(x)$ process, hence obviously ${ }^{-\lambda} Q_{z}^{\delta}$ to $Q_{z}^{\delta}$, the law of a squared $\operatorname{BES}^{\delta}(\sqrt{z})$ process.

Proposition 1. For every $\lambda \in \mathbb{R}$ and $x \geqslant 0$,

$$
\begin{equation*}
\left.{ }^{-\lambda} P_{x}^{\delta}\right|_{\mathcal{F}_{\mathrm{t}}}=\left.\exp \left\{-\frac{\lambda}{2}\left[R_{t}^{2}-x^{2}-\delta t\right]-\frac{\lambda^{2}}{2} \int_{0}^{t} R_{s}^{2} \mathrm{~d} s\right\} \cdot P_{x}^{\delta}\right|_{\mathcal{F}_{t}} . \tag{8}
\end{equation*}
$$

Proof. All that is needed to justify (8) is to verify that the Girsanov local martingale which appears in (8) is in fact a martingale. But this follows from the fact that both diffusions with laws ${ }^{-\lambda} P_{x}^{\delta}$ and $P_{x}^{\delta}$ are non-explosive; see, for example, McKean's (1969, Section 3.7) presentation of Girsanov's theorem in the case of explosion.

Remark 1. More generally, we can replace in (8) the restrictions to the $\sigma$-fields $\mathcal{F}_{t}$ by restrictions to $\mathcal{F}_{T} \cap(T<\infty)$, for any $\left(\mathcal{F}_{\mathfrak{t}}\right)$-stopping time $T$.

Corollary 1. For $\delta \geqslant 2(\delta<2)$, and $x>0,\left(R_{t}, t \geqslant 0\right)$ does not visit 0 almost surely (visits 0 almost surely) under ${ }^{-\lambda} P_{x}^{\delta}$.

Proof. The result for $\lambda=0$ is well known, and it extends to any $\lambda \in \mathbb{R}$ with the help of (8).
The following consequence of Proposition 1 will be helpful later in transferring results valid for ${ }^{-\lambda} P_{x}^{\delta}$, with $\lambda>0$, to ${ }^{\lambda} P_{x}^{\delta}$.

Corollary 2. For every $\lambda \in \mathbb{R}$ and every stopping time $T$ with respect to $\left(\mathcal{F}_{\mathfrak{t}}\right)$, we have the absolute continuity relationship

$$
\begin{equation*}
\left.{ }^{\lambda} P_{x}^{\delta}\right|_{\mathcal{F}_{\mathrm{T}} \cap(T<\infty)}=\left.\exp \left(\lambda\left(R_{T}^{2}-x-\delta T\right)\right) \cdot{ }^{-\lambda} P_{x}^{\delta}\right|_{\mathcal{F}_{T} \cap(T<\infty)} . \tag{9}
\end{equation*}
$$

Because $R_{t}=\sqrt{Z_{t}}$ reaches 0 almost surely for $\delta<2$, we need to take care when using Itô's formula and expressing $\left(R_{t}\right)$ as the solution of some stochastic equation. For $\delta>1$, it is the solution to the equation

$$
\mathrm{d} R_{t}=\left(\frac{\delta-1}{2 R_{t}}-\lambda R_{t}\right) \mathrm{d} t+\mathrm{d} W_{t}, \quad R_{0}=x=\sqrt{z}
$$

For $\delta=1$ we have, with the Itô-Tanaka formula,

$$
\left|R_{t}\right|=|x|-\lambda \int_{0}^{t}\left|R_{s}\right| \mathrm{d} s+\tilde{W}_{t}+L_{t},
$$

where $\left(R_{t}\right)$ is a ${ }^{-\lambda} P_{x}^{1}$ process, $\tilde{W}_{t} \equiv \int_{0}^{t} \operatorname{sgn}\left(R_{s}\right) \mathrm{d} W_{s}$ is standard Brownian motion and $\left(L_{t}\right)$ is the local time of $R$. For $\delta<1$ we obtain, from (48) in Appendix A,

$$
R_{t}=x+\frac{\delta-1}{2} \text { p.v. } \int_{0}^{t} \frac{\mathrm{~d} s}{R_{s}}-\lambda \int_{0}^{t} R_{s} \mathrm{~d} s+\hat{W}_{t},
$$

where $\left(\hat{W}_{t}\right)$ is standard Brownian motion under ${ }^{-\lambda} P^{\delta}$ and p.v. denotes the principal value.
Our aim is to find the law of

$$
\begin{equation*}
T_{x \rightarrow y} \equiv \inf \left\{t \mid R_{t}=y\right\}, \tag{10}
\end{equation*}
$$

the first time a radial Ornstein-Uhlenbeck process $\left(R_{t}\right)$ with parameter $-\lambda$ starting at $x \geqslant 0$ hits the level $y$. We distinguish between the cases $0 \leqslant y<x$ and $0 \leqslant x<y$. For $\delta<2$, we have ${ }^{-\lambda} P_{x}^{\delta}\left(T_{x \rightarrow 0}<\infty\right)>0$, that is, the process $\left(R_{t}\right)$ may reach 0 ; if $\delta<2$ and $\lambda>0$, then ${ }^{-\lambda} P_{x}^{\delta}\left(T_{x \rightarrow 0}<\infty\right)=1$, that is, $\left(R_{t}\right)$ reaches 0 almost surely and hence every $y$ almost surely, $0 \leqslant y<x$. For $\delta \geqslant 2$, we have ${ }^{-\lambda} P_{x}^{\delta}\left(T_{x \rightarrow y}<\infty\right)=1$ almost surely for every $y \geqslant x$.

Call ${ }^{-\lambda} P_{x}^{\delta}$ the law of a $\delta$-dimensional radial Ornstein-Uhlenbeck process with parameter $-\lambda$. The density ${ }^{-\lambda} p_{x}^{\delta}(t)$ of the first time a radial Ornstein-Uhlenbeck process hits 0 is calculated in Elworthy et al. (1999, Corollary 3.10) by using a time-reversal argument from $T_{x \rightarrow 0}$, that is, for $y=0$ the problem is already solved:

$$
\begin{equation*}
{ }^{-\lambda} p_{x}^{\delta}(t)=\frac{x^{2-\delta}}{2^{\nu} \Gamma(v)} \exp \left[\frac{\lambda}{2}\left(\delta t+x^{2}(1-\operatorname{coth}(\lambda t))\right)\right]\left[\frac{\lambda}{\sinh (\lambda t)}\right]^{(4-\delta) / 2}, \tag{11}
\end{equation*}
$$

where $\delta<2, \lambda>0, x>0$ and $v=\frac{4-\delta}{2}-1$.
We have, for $0 \leqslant y \leqslant x$,

$$
T_{x \rightarrow 0} \stackrel{(\text { law })}{=} T_{x \rightarrow y}+T_{y \rightarrow 0},
$$

where $T_{x \rightarrow y}$ and $T_{y \rightarrow 0}$ may be assumed to be independent because of the strong Markov property. Hence, with (11) we obtain for the Laplace transform (LT) of $T_{x \rightarrow y}$,

$$
\begin{equation*}
{ }^{-\lambda} \mathrm{E}_{x}^{\delta}\left[\exp \left(-\mu T_{x \rightarrow y}\right)\right]=\frac{\phi_{x}(\mu)}{\phi_{y}(\mu)}, \tag{12}
\end{equation*}
$$

where, still for $\lambda>0$, we find that

$$
\phi_{x}(\mu)={ }^{-\lambda} \mathrm{E}_{x}^{\delta}\left[\exp \left(-\mu T_{x \rightarrow 0}\right)\right]=\int_{0}^{\infty} \exp (-\mu t)^{-\lambda} p_{x}^{\delta}(t) \mathrm{d} t
$$

Results for the case $\lambda<0$ will be derived from those for $\lambda>0$ with the help of Corollary 2 . Our main results are Theorems 1-4 and Corollaries 3 and 4, where we derive explicit expressions of the LTs of first hitting times by radial Ornstein-Uhlenbeck processes with arbitrary $x, y \geqslant 0$. But let us first concentrate on the case $\lambda=0$, that is, Bessel processes.

### 2.1. First hitting times of Bessel processes

In order to find an expression for the law and/or the LT of certain first hitting times of Bessel processes, it is convenient to consider time-reversed Bessel processes. More generally, for time-reversed diffusion processes, see Appendix B. Let $\left(X_{t}\right)$ be a Bessel process with dimension $\delta<2$ starting at $x>0$. The time-reversed process ( $X_{\left(T_{x \rightarrow 0}\right)-u}, u \leqslant T_{x \rightarrow 0}$ ) enjoys the following relationship with ( $\hat{X}_{u}, u \geqslant 0$ ), a $\hat{\delta}$-dimensional Bessel process starting at 0 , with $\hat{\delta} \equiv 4-\delta$ (see Appendix B):

$$
\left(X_{\left(T_{x \rightarrow 0}\right)-u}, u \leqslant T_{x \rightarrow 0}\right) \stackrel{(\mathrm{law})}{=}\left(\hat{X}_{u}, u \leqslant \hat{L}_{0 \rightarrow x}\right),
$$

where

$$
\hat{L}_{0 \rightarrow x}=\sup \left\{t \mid \hat{X}_{t}=x\right\},
$$

which is finite since $\left\{\hat{X}_{u}, u \geqslant 0\right\}$ is transient (which follows from $\hat{\delta}>2$ ). In particular, as remarked in Getoor and Sharpe (1979) and Sharpe (1980), $\hat{L}_{0 \rightarrow x}$ under $P_{0}^{\delta}$ has the same law as $T_{x \rightarrow 0}$ under $P_{x}^{\delta}$. We know (Getoor 1979; Pitman and Yor 1980) that

$$
\begin{equation*}
\hat{L}_{0 \rightarrow x} \stackrel{\text { (law) }}{=} \frac{x^{2}}{2 Z_{\hat{v}}}, \tag{13}
\end{equation*}
$$

where $Z_{\hat{v}}$ is a gamma variable with parameter $\hat{v} \equiv \hat{\delta} / 2-1$, that is,

$$
\begin{equation*}
P\left(Z_{\hat{v}} \in \mathrm{~d} t\right)=\frac{t^{\hat{\nu}-1} \mathrm{e}^{-t}}{\Gamma(\hat{v})} \mathrm{d} t \tag{14}
\end{equation*}
$$

and hence

$$
\begin{equation*}
P_{x}^{\delta}\left(T_{x \rightarrow 0} \in \mathrm{~d} t\right)=P_{0}^{\hat{\delta}}\left(\hat{L}_{0 \rightarrow x} \in \mathrm{~d} t\right)=\frac{1}{t \Gamma(\hat{v})}\left(\frac{x^{2}}{2 t}\right)^{\hat{v}} \mathrm{e}^{-x^{2} / 2 t} \mathrm{~d} t \tag{15}
\end{equation*}
$$

We note that (11) was obtained in Elworthy et al. (1999) in an analogous way, additionally making use of Girsanov's transformation.

For $y \neq 0, y<x$, the first hitting time $T_{x \rightarrow y}$ is not distributed as $\hat{L}_{y \rightarrow x}$, the last exit time of $x$ by ( $\hat{X}_{u}$ ) starting at $y$. In fact, using the same time-reversal argument as above, we find
that $T_{x \rightarrow y}$ has the same law as $\hat{L}_{y / x}$, where $\hat{L}_{y / x}$ denotes the last exit time of $x$ by $\left(\hat{X}_{\hat{L}_{y}+u}\right)$, with $\left(\hat{X}_{u}\right)$ starting at the point 0 at time 0 . In other words, we have $T_{x \rightarrow y}=\hat{L}_{y / x}$ in law and

$$
\begin{equation*}
\hat{L}_{0 \rightarrow x} \stackrel{(\text { law })}{=} \hat{L}_{0 \rightarrow y}+\hat{L}_{y / x}, \tag{16}
\end{equation*}
$$

where $\hat{L}_{0 \rightarrow y}$ and $\hat{L}_{y / x}$ are independent because of the strong Markov property (or path decomposition) at last exit times (for a survey, see Millar 1977). Figure 1 illustrates the situation.

Figure 1. Simulated path of a $\mathrm{BES}_{x}^{\delta}$ process, $\delta<2$, starting at $x=5$.
Our aim is to find an expression for the LT of $\hat{L}_{y / x}$ :

$$
\mathrm{E}_{0}^{\hat{\delta}}\left[\exp \left(-\frac{1}{2} \alpha^{2} \hat{L}_{y / x}\right)\right]=\frac{\mathrm{E}_{0}^{\hat{\delta}}\left[\exp \left(-\frac{1}{2} \alpha^{2} \hat{L}_{0 \rightarrow x}\right)\right]}{\mathrm{E}_{0}^{\hat{\delta}}\left[\exp \left(-\frac{1}{2} \alpha^{2} \hat{L}_{0 \rightarrow y}\right)\right]} .
$$

With (15), and with the Sommerfeld integral representation of the Macdonald function $K_{\hat{v}}=K_{v}$, also known as the modified Bessel function of the third kind of order $\hat{v}=-v$ (see, for example, Lebedev 1972, p. 119, (5.10.25)),

$$
\begin{equation*}
K_{\nu}(z)=\frac{1}{2}\left(\frac{z}{2}\right)^{v} \int_{0}^{\infty} \mathrm{e}^{-t-z^{2} / 4 t} t^{-\nu-1} \mathrm{~d} t, \tag{17}
\end{equation*}
$$

we obtain the LT of $\hat{L}_{0 \rightarrow y}$ :

$$
\mathrm{E}_{0}^{\hat{\delta}}\left[\exp \left(-\frac{1}{2} \alpha^{2} \hat{L}_{0 \rightarrow y}\right)\right]=\frac{(\alpha y) \hat{\nu} K_{\hat{v}}(\alpha y)}{2^{\hat{v}-1} \Gamma(\hat{v})}
$$

Thus (see also Getoor 1979; Getoor and Sharpe 1979; Kent 1978a, (3.7); and Pitman and Yor 1980), for $y<x, y \neq 0$,

$$
\begin{aligned}
\mathrm{E}_{x}^{\delta}\left[\exp \left(-\frac{1}{2} \alpha^{2} T_{x \rightarrow y}\right)\right] & =\mathrm{E}_{0}^{\hat{\delta}}\left[\exp \left(-\frac{1}{2} \alpha^{2} \hat{L}_{y / x}\right)\right] \\
& =\left(\frac{x}{y}\right)^{\hat{v}} \frac{K_{\hat{v}}(\alpha x)}{K_{\hat{v}}(\alpha y)}=\left(\frac{y}{x}\right)^{v} \frac{K_{v}(\alpha x)}{K_{v}(\alpha y)} .
\end{aligned}
$$

This formula might also have been obtained by looking for a function $\phi$ such that $\phi\left(X_{t}\right) \exp \left(-\frac{1}{2} \alpha^{2} t\right)$ is a local martingale.

Likewise, in the case $0<x<y$ we have (see Kent 1978a, (3.8); Pitman and Yor 1980)

$$
\mathrm{E}_{x}^{\delta}\left[\exp \left(-\frac{1}{2} \alpha^{2} T_{x \rightarrow y}\right)\right]=\left(\frac{y}{x}\right)^{v} \frac{I_{v}(\alpha x)}{I_{v}(\alpha y)},
$$

with $I_{v}$ the modified Bessel function of the first kind of order $v$. Since

$$
\begin{equation*}
\lim _{\varepsilon \downarrow 0} \frac{I_{\nu}(\mu \varepsilon)}{\varepsilon^{v}}=\left(\frac{\mu}{2}\right)^{v} \Gamma^{-1}(v+1), \tag{18}
\end{equation*}
$$

we obtain, for $x=0, y>0$,

$$
\mathrm{E}_{0}^{\delta}\left[\exp \left(-\frac{1}{2} \alpha^{2} T_{0 \rightarrow y}\right)\right]=\left(\frac{\alpha}{2}\right)^{v} \Gamma^{-1}(v+1) \frac{y^{v}}{I_{\nu}(\alpha y)} .
$$

We remark that for Brownian motion, that is, in the case $\delta=1$, we have

$$
T_{x \rightarrow 0} \stackrel{(\text { law })}{=} T_{y \rightarrow 0}+\left(\tilde{T}_{(x-y) \rightarrow 0}\right),
$$

where $x>y \geqslant 0$ and ( $\tilde{T}_{(x-y) \rightarrow 0}$ ) denotes an independent copy of $T_{x \rightarrow y}$. We know the density of $T_{x \rightarrow 0}$ for Brownian motion,

$$
\sigma_{x}(t)=\frac{x}{\sqrt{2 \pi t^{3}}} \mathrm{e}^{-x^{2} / 2 t},
$$

that is, we know the density of $T_{(x-y) \rightarrow 0}$ and hence the density of $T_{x \rightarrow y}$. Note that

$$
\mathrm{E}_{x}^{1}\left[\exp \left(-\frac{1}{2} \alpha^{2} T_{x \rightarrow 0}\right)\right]=\int_{0}^{\infty} \mathrm{e}^{-\alpha^{2} t / 2} \sigma_{x}(t) \mathrm{d} t=\mathrm{e}^{-\alpha x} .
$$

### 2.2. First hitting times of radial Ornstein-Uhlenbeck processes

Our aim is to find an explicit expression of the LT (12) of $T_{x \rightarrow y}$ for a radial OrnsteinUhlenbeck process $R$. We pursue an idea for which we are indebted to Breiman (1967) and exploit the relation between CIR and BES processes. Breiman considers an OrnsteinUhlenbeck process $Y(u)=\mathrm{e}^{-u} B\left(\frac{1}{2} \mathrm{e}^{2 u}\right)$ (our $\frac{1}{2}$ corrects a misprint in Breiman) with $B$ standard Brownian motion, $B(1)=0$, and gives the LT of the first hitting time $T_{c}$ for $Y$ from the boundaries $\pm c$ :

$$
\mathrm{E}\left(\mathrm{e}^{-\alpha T_{c}}\right)=\tilde{D}_{\alpha}^{-1}(c),
$$

where

$$
\tilde{D}_{\alpha}(c)=\frac{2^{1-\alpha / 2}}{\Gamma(\alpha / 2)} \int_{0}^{\infty} \mathrm{e}^{-t^{2} / 2} t^{\alpha-1} \cosh (c t) \mathrm{d} t,
$$

see also Borodin and Salminen (2002, II.7.2.0.1, p. 542). First hitting times of OrnsteinUhlenbeck processes are also studied by Ricciardi and Sato (1988) and Horowitz (1985).
A $\delta$-dimensional radial Ornstein-Uhlenbeck process $R_{t}$ with parameter $-\lambda, R_{0}=0$, can be written as

$$
\begin{equation*}
R_{t}=\mathrm{e}^{-\lambda t} X\left(\frac{\mathrm{e}^{2 \lambda t}-1}{2 \lambda}\right), \tag{19}
\end{equation*}
$$

where $X$ is a $\mathrm{BES}^{\delta}$ process, $X_{0}=0$. We are interested in the first time $R_{t}$ hits the level $x>0$, which we denote $T_{x}$. Although some of our next arguments may work for $\lambda<0$, we restrict ourselves for now to the case $\lambda>0$. Later, to deal with the case $\lambda<0$, we shall use Corollary 4. Analogously to Breiman (1967), we assume that $D_{\alpha}$ is a function such that $\left\{D_{\alpha}\left(R_{t}\right) \mathrm{e}^{-\alpha t}, t \geqslant 0\right\}$ is a martingale with respect to the filtration of $X\left(\left(\mathrm{e}^{2 \lambda t}-1\right) / 2 \lambda\right)$. Equivalently, $\left\{D_{\alpha}\left((2 \lambda u+1)^{-1 / 2} X_{u}\right)(2 \lambda u+1)^{-\alpha / 2 \lambda}, u \geqslant 0\right\}$ is a martingale with respect to the filtration of $X_{u}$. This means, via Itô's formula, that $\left\{D_{\alpha}\left(r(2 \lambda u+1)^{-1 / 2}\right)(2 \lambda u+1)^{-\alpha / 2 \lambda}\right.$, $r \geqslant 0, u \geqslant 0\}$ solves

$$
\frac{1}{2} \frac{\mathrm{~d}^{2}}{\mathrm{~d} r^{2}}+\frac{\delta-1}{2 r} \frac{\mathrm{~d}}{\mathrm{~d} r}+\frac{\mathrm{d}}{\mathrm{~d} u}=0,
$$

that is, it is a space-time harmonic function with respect to

$$
\frac{1}{2} \frac{\mathrm{~d}^{2}}{\mathrm{~d} r^{2}}+\frac{\delta-1}{2 r} \frac{\mathrm{~d}}{\mathrm{~d} r}+\frac{\mathrm{d}}{\mathrm{~d} u} .
$$

Further, we assume that $\left(D_{a}(r), r \leqslant \rho\right)$ is bounded for every $\rho$. Then $\left\{D_{\alpha}\left(R_{t}\right) \mathrm{e}^{-\alpha t}, t<T_{x}\right\}$ is bounded. Applying the optional stopping theorem (see, for example, Revuz and Yor 1999, Chapter II, §3), we have

$$
{ }^{-\lambda} \mathrm{E}_{0}^{\delta}\left[D_{\alpha}\left(R_{T_{x}}\right) \mathrm{e}^{-\alpha T_{x}}\right]=D_{\alpha}(0),
$$

thus

$$
{ }^{-\lambda} \mathrm{E}_{0}^{\delta}\left[\mathrm{e}^{-\alpha T_{x}}\right]=\frac{D_{\alpha}(0)}{D_{\alpha}(x)} .
$$

This motivates us to find the function $D_{\alpha}$ explicitly. First, we derive the space-time harmonic functions for Bessel processes.
We know from Widder (1975, Theorem 14.1.1) that the most general $\mathbb{R}^{+}$-valued spacetime harmonic function $h(x, t)$ with $x \in \mathbb{R}^{n}, t \geqslant 0$, with respect to $\frac{1}{2} \Delta_{x}+\mathrm{d} / \mathrm{d} t$ is of the form

$$
\begin{equation*}
h(x, t)=\int_{\mathbb{R}^{n}} \exp \left(\xi \cdot x-\frac{|\xi|^{2} t}{2}\right) m(\mathrm{~d} \xi), \tag{20}
\end{equation*}
$$

where $m$ is a positive measure. We assume $h$ is not identically zero. From (20) we obtain the general positive space-time harmonic function $\left(\tilde{h}(r, t), r, t \in \mathbb{R}_{+}\right)$with respect to

$$
\frac{1}{2} \frac{\mathrm{~d}^{2}}{\mathrm{~d} r^{2}}+\frac{n-1}{2 r} \frac{\mathrm{~d}}{\mathrm{~d} r}+\frac{\mathrm{d}}{\mathrm{~d} t}
$$

via

$$
\begin{equation*}
\tilde{h}(r, t)=\int_{S^{n-1}} h(\theta r, t) \sigma(\mathrm{d} \theta)=\int_{\mathbb{R}^{n}} \int_{S^{n-1}} \exp \left(\xi \cdot \theta r-\frac{|\xi|^{2} t}{2}\right) \sigma(\mathrm{d} \theta) m(\mathrm{~d} \xi) \tag{21}
\end{equation*}
$$

where $\sigma$ is the uniform probability measure on the unit sphere $S^{n-1}$. We have the following integral representation for the Bessel function $I_{v}$

$$
I_{\nu}(|\eta|)=\frac{|\eta / 2|^{v}}{\Gamma(v+1)} \int_{S^{n-1}} \exp (\eta \cdot \theta) \sigma(\mathrm{d} \theta)
$$

$\eta \in \mathbb{R}^{n}, v=n / 2-1$ (see Lebedev 1972, §5.10; Pitman and Yor 1980, (5.c2)); substituting in (21), we have

$$
\tilde{h}(r, t)=\Gamma(v+1) 2^{v} \int_{\mathbb{R}^{n}} I_{v}(|\xi| r) \exp \left(-\frac{|\xi|^{2} t}{2}\right)(|\xi| r)^{-v} m(\mathrm{~d} \xi)
$$

Replacing $|\xi|$ with $u \in \mathbb{R}_{+}$, we obtain a space-time harmonic function $\tilde{h}$ with respect to a Bessel process with index $\nu$ :

$$
\tilde{h}(r, t)=\Gamma(v+1) 2^{v} \int_{0}^{\infty} I_{v}(u r) \mathrm{e}^{-u^{2} t / 2}(u r)^{-v} \tilde{m}(\mathrm{~d} u)
$$

We believe this formula is true for all dimensions, although a simple proof still eludes us. In fact, we only need to find a function $D_{\alpha}$ such that

$$
\begin{aligned}
D_{\alpha}\left(\frac{r}{\sqrt{2 \lambda t+1}}\right)(2 \lambda t+1)^{-\alpha / 2 \lambda} & =\tilde{h}(r, t) \\
& =\Gamma(v+1) 2^{v} \int_{0}^{\infty} I_{v}(u r) \mathrm{e}^{-u^{2} t / 2} r^{-v} f(u) \mathrm{d} u
\end{aligned}
$$

with an $L^{1}$-function $f: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$; then $\left\{D_{\alpha}\left(R_{t}\right) \mathrm{e}^{-\alpha t}, t \leqslant T_{x}\right\}$ is a bounded martingale and the optional stopping theorem applies.

Let us first look for $D_{\alpha}$ such that

$$
D_{\alpha}\left(\frac{r}{\sqrt{2 \lambda t+1}}\right)(2 \lambda t+1)^{-\alpha / 2 \lambda}=\Gamma(v+1)\left(\frac{2}{r}\right)^{v} \int_{0}^{\infty} I_{v}(r u) \mathrm{e}^{-u^{2} t / 2} f(u) \mathrm{d} u
$$

or equivalently,

$$
\begin{align*}
D_{\alpha}(y) & =(2 \lambda t+1)^{\alpha / 2 \lambda-v / 2} \Gamma(v+1)\left(\frac{2}{y}\right)^{v} \int_{0}^{\infty} I_{v}(\sqrt{2 \lambda t+1} y u) \mathrm{e}^{-u^{2} t / 2} f(u) \mathrm{d} u \\
& =(2 \lambda t+1)^{\alpha / 2 \lambda-(v+1) / 2} \Gamma(v+1)\left(\frac{2}{y}\right)^{v} \int_{0}^{\infty} I_{\nu}(\eta y) \mathrm{e}^{-\eta^{2} / 4 \lambda} g\left(\frac{\eta}{\sqrt{2 \lambda t+1}}\right) \mathrm{d} \eta, \tag{22}
\end{align*}
$$

with $g(v)=\mathrm{e}^{-v^{2} / 4 \lambda} f(v)$. The right-hand side of (22) should not depend on $t$, hence we may choose $g(v) \equiv c_{0} v^{\alpha / \lambda-\nu-1}$, with a constant $c_{0}>0$, or

$$
\begin{equation*}
f(v) \equiv c_{0} v^{\alpha / \lambda-v-1} \mathrm{e}^{-v^{2} / 4 \lambda} \tag{23}
\end{equation*}
$$

$\left(\in \mathcal{L}^{1}\right)$. We see that $D_{\alpha}\left(r(2 \lambda t)^{-1 / 2}\right)(2 \lambda t)^{-\alpha / 2 \lambda}=\tilde{h}(r, t)$, and certainly also $\tilde{h}(r, t+c)$ with a constant $c$, is a space-time harmonic function with respect to

$$
\frac{1}{2} \frac{\mathrm{~d}^{2}}{\mathrm{~d} r^{2}}+\frac{\delta-1}{2 r} \frac{\mathrm{~d}}{\mathrm{~d} r}+\frac{\mathrm{d}}{\mathrm{~d} t} .
$$

Thus

$$
D_{\alpha}\left(\frac{r}{\sqrt{2 \lambda t+1}}\right)(2 \lambda t+1)^{-\alpha / 2 \lambda}=\Gamma(v+1)\left(\frac{2}{r}\right)^{v} \int_{0}^{\infty} I_{\nu}(r u) \exp \left(-u^{2}(t+1 / 2 \lambda) / 2\right) f(u) \mathrm{d} u
$$

with $f$ in (23), and we find that

$$
\begin{equation*}
D_{\alpha}(y)=\Gamma(v+1)\left(\frac{2}{y}\right)^{v} \int_{0}^{\infty} I_{\nu}(\eta y) \mathrm{e}^{-\eta^{2} / 4 \lambda} \eta^{\alpha / \lambda-\nu-1} \mathrm{~d} \eta . \tag{24}
\end{equation*}
$$

With (18) we see that

$$
D_{\alpha}(0)=\int_{0}^{\infty} \mathrm{e}^{-\eta^{2} / 4 \lambda} \eta^{\alpha / \lambda-1} \mathrm{~d} \eta=2^{\alpha / \lambda-1} \lambda^{\alpha / 2 \lambda} \Gamma\left(\frac{\alpha}{2 \lambda}\right) .
$$

Recalling the definition of the confluent hypergeometric function $\phi$,

$$
\phi(a, b ; z)=\sum_{j=0}^{\infty} \frac{(a)_{j}}{(b)_{j}} \frac{z^{j}}{j!},
$$

where $b \neq 0,-1,-2, \ldots$ and

$$
(r)_{0}=1, \quad(r)_{j}=\frac{\Gamma(r+j)}{\Gamma(r)}=r(r+1) \ldots(r+j-1)
$$

$j=1,2, \ldots$ (see Lebedev 1972, (9.9.1)), and of Whittaker's functions

$$
M_{k, \mu}(z)=z^{\mu+1 / 2} \mathrm{e}^{-z / 2} \phi\left(\mu-k+\frac{1}{2}, 2 \mu+1 ; z\right),
$$

(see Lebedev 1972, (9.13.16)), we finally obtain, together with Bateman Manuscript Project (1954, 4.16.(20)), the following theorem.

Theorem 1. The $L T$ of the first time $T_{x}=\inf \left\{t \mid R_{t}=x\right\}$ a $\delta$-dimensional radial OrnsteinUhlenbeck process $R_{t}$ started at 0 with parameter $-\lambda$ hits the level $x$ is

$$
\begin{aligned}
{ }^{-\lambda} \mathrm{E}_{0}^{\delta}\left(\mathrm{e}^{-\alpha T_{x}}\right) & =\frac{2^{\alpha / \lambda-v-1} x^{\nu} \Gamma(\alpha / 2 \lambda) \lambda^{\alpha / 2 \lambda}}{\Gamma(v+1) \int_{0}^{\infty} I_{\nu}(\eta x) \mathrm{e}^{-\eta^{2} / 4 \lambda} \eta^{\alpha / \lambda-\nu-1} \mathrm{~d} \eta} \\
& =\frac{(\sqrt{\lambda} x)^{\nu+1} \mathrm{e}^{-\lambda x^{2} / 2}}{M_{(-\alpha / \lambda+\nu+1) / 2, v / 2}\left(\lambda x^{2}\right)} \\
& =\frac{1}{\phi\left(\alpha / 2 \lambda, v+1 ; \lambda x^{2}\right)} .
\end{aligned}
$$

For $0<y<x$, we have

$$
T_{0 \rightarrow x}=T_{0 \rightarrow y}+T_{y \rightarrow x},
$$

where $T_{0 \rightarrow y}$ and $T_{y \rightarrow x}$ are independent because of the strong Markov property. We deduce the following corollary:

Corollary 3. The LT of the first time $T_{x}=\inf \left\{t \mid R_{t}=x\right\}$ a $\delta$-dimensional radial OrnsteinUhlenbeck process $R_{t}$ starting at $y, 0<y<x$, with parameter $-\lambda$ hits the level $x$ is

$$
\begin{aligned}
{ }^{-\lambda} \mathrm{E}_{y}^{\delta}\left(\mathrm{e}^{-\alpha T_{x}}\right) & =\left(\frac{x}{y}\right)^{v+1} \exp \left(\lambda\left(y^{2}-x^{2}\right) / 2\right) \frac{M_{(-\alpha / \lambda+v+1) / 2, v / 2}\left(\lambda y^{2}\right)}{M_{(-\alpha / \lambda+v+1) / 2, v / 2}\left(\lambda x^{2}\right)} \\
& =\frac{\phi\left(\alpha / 2 \lambda, v+1 ; \lambda y^{2}\right)}{\phi\left(\alpha / 2 \lambda, v+1 ; \lambda x^{2}\right)} .
\end{aligned}
$$

We obtain the LT of $T_{x}$ in the case $0<x<y$ analogously. Note that here we need to use the modified Bessel functions of the third kind $K_{v}$ instead of the modified Bessel functions of the first kind $I_{v}$ such that the required uniform integrability assumption is satisfied. With the confluent hypergeometric function of the second kind $\psi$,

$$
\psi(a, b ; z)=\frac{\Gamma(1-b)}{\Gamma(1+a-b)} \phi(a, b ; z)+\frac{\Gamma(b-1)}{\Gamma(a)} z^{1-b} \phi(1+a-b, 2-b ; z),
$$

(see Lebedev 1972, (9.10.3)), and with Whittaker's functions

$$
W_{k, \mu}(z)=z^{\mu+\frac{1}{2}} \mathrm{e}^{-z / 2} \psi\left(\mu-k+\frac{1}{2} ; 2 \mu+1 ; z\right),
$$

(see Lebedev 1972, (9.13.16)), we obtain, with the Bateman Manuscript Project (1954, 4.16.(37)), the following theorem

Theorem 2. The LT of the first time $T_{x}=\inf \left\{t \mid R_{t}=x\right\}$ a $\delta$-dimensional radial OrnsteinUhlenbeck process $R_{t}$ starting at $y, 0<x<y$, with parameter $-\lambda$ hits the level $x$ is

$$
\begin{aligned}
{ }^{-\lambda} \mathrm{E}_{y}^{\delta}\left(\mathrm{e}^{-\alpha T_{x}}\right) & =\left(\frac{x}{y}\right)^{v} \frac{\int_{0}^{\infty} K_{v}(\eta y) \mathrm{e}^{-\eta^{2} / 4 \lambda} \eta^{\alpha / \lambda-v-1} \mathrm{~d} \eta}{\int_{0}^{\infty} K_{v}(\eta x) \mathrm{e}^{-\eta^{2} / 4 \lambda} \eta^{\alpha / \lambda-v-1} \mathrm{~d} \eta} \\
& =\left(\frac{x}{y}\right)^{v+1} \mathrm{e}^{\lambda\left(y^{2}-x^{2}\right) / 2} \frac{W_{(-\alpha / \lambda+v+1) / 2, v / 2}\left(\lambda y^{2}\right)}{W_{(-\alpha / \lambda+v+1) / 2, v / 2}\left(\lambda x^{2}\right)} \\
& =\frac{\psi\left(\alpha / 2 \lambda, v+1 ; \lambda y^{2}\right)}{\psi\left(\alpha / 2 \lambda, v+1 ; \lambda x^{2}\right)}
\end{aligned}
$$

With

$$
K_{v}(x) \sim \frac{\Gamma(-v)}{2^{v+1}} x^{v}
$$

for $x \rightarrow 0$ and $v<0$, we immediately obtain the following corollary.
Corollary 4. The LT of the first time $T_{0}=\inf \left\{t \mid R_{t}=0\right\}$ that a $\delta$-dimensional radial Ornstein-Uhlenbeck process $R_{t}$, starting at $y$ with $\delta<2$ with parameter $-\lambda$, hits 0 is

$$
\begin{aligned}
{ }^{-\lambda} \mathrm{E}_{y}^{\delta}\left(\mathrm{e}^{-\alpha T_{0}}\right) & =\frac{2^{v-\alpha / \lambda+2} y^{-v} \lambda^{-\alpha / 2 \lambda}}{\Gamma(\alpha / 2 \lambda) \Gamma(-v)} \int_{0}^{\infty} K_{v}(\eta y) \mathrm{e}^{-\eta^{2} / 4 \lambda} \eta^{\alpha / \lambda-v-1} \mathrm{~d} \eta \\
& =4(\sqrt{\lambda} y)^{-v-1} \mathrm{e}^{\lambda y^{2} / 2} \frac{\Gamma(\alpha / 2 \lambda-v)}{\Gamma(-v)} W_{(-\alpha / \lambda+v+1) / 2, v / 2}\left(\lambda y^{2}\right) \\
& =4 \frac{\Gamma(\alpha / 2 \lambda-v)}{\Gamma(-v)} \psi\left(\frac{\alpha}{2 \lambda}, v+1 ; \lambda y^{2}\right)
\end{aligned}
$$

For $\delta \geqslant 2$ we have $T_{0}=\infty$ almost surely, that is, ${ }^{-\lambda} \mathrm{E}_{y}^{\delta}\left(\mathrm{e}^{-\alpha T_{0}}\right)=0$.
Remark 2. In the case treated in Corollary 4 we know the density of $T_{0}$ by (11). We note that, for $\delta=1$, it is also claimed in Leblanc and Scaillet (1998) and Leblanc et al. (2000) that the closed formula (11) also extends simply to the distribution of $T_{x}$ (for $x \neq 0$ ) under ${ }^{-\lambda} P_{y}^{1}$. We explain elsewhere (Göing-Jaeschke and Yor 2003) that this is incorrect, as was also remarked by David Mumford and (independently) Larbi Alili, and we give an expression of the density in terms of $\mathrm{BES}^{(3)}$ bridges. However, we have not obtained an explicit form for this density.

Remark 3. The LTs of first hitting times of squared $\delta$-dimensional Bessel or radial OrnsteinUhlenbeck processes are obtained immediately. Moreover, from the investigation of the behaviour of squared Bessel or radial Ornstein-Uhlenbeck processes with negative dimensions or negative starting points (see Sections 1 and 3), we have no difficulty in extending the results above to, for example, the case $x>0>y$.

Remark 4. In disguised versions the formulae above also appear in Pitman and Yor (1980, Chapter 12) and Eisenbaum (1990).

We now show how to deduce the laws of first hitting times in the case $\lambda<0$ for our previous formulae.

Theorem $3(\lambda<\mathbf{0})$. Let $\mu=-\lambda>0$. The $L T$ of the first time $T_{x}=\inf \left\{t \mid R_{t}=x\right\}$ a $\delta$ dimensional radial Ornstein-Uhlenbeck process $R_{t}$ starting at 0 with parameter $\mu$ hits the level $x$ is

$$
{ }^{\mu} \mathrm{E}_{0}^{\delta}\left(\mathrm{e}^{-\alpha T_{x}}\right)=\frac{\mathrm{e}^{\mu x^{2}}}{\phi\left((\alpha+\delta \mu) / 2 \mu, \delta / 2 ; \mu x^{2}\right)} .
$$

Theorem $4(\lambda<\mathbf{0})$. Let $\mu=-\lambda>0$. The LT of the first time $T_{x}=\inf \left\{t \mid R_{t}=x\right\}$ a $\delta$ dimensional radial Ornstein-Uhlenbeck process $R_{t}$ starting at $y, 0<x<y$, with parameter $\mu$ hits the level $x$ is

$$
{ }^{\mu} \mathrm{E}_{y}^{\delta}\left(\mathrm{e}^{-\alpha T_{x}}\right)=\mathrm{e}^{\mu\left(x^{2}-y^{2}\right)} \frac{\psi\left((\alpha+\delta \mu) / 2 \mu, \delta / 2 ; \mu y^{2}\right)}{\psi\left((\alpha+\delta \mu) / 2 \mu, \delta / 2 ; \mu x^{2}\right)} .
$$

The $\lambda<0$ versions of Corollaries 3 and 4 are left to the reader.
Proof of Theorems 3 and 4. From Corollary 2 we know that for any $f: \mathbb{R}_{+} \times \mathbb{R}_{+} \rightarrow \mathbb{R}$, $f\left(R_{t}, t\right)$ is a ${ }^{-\lambda} P_{x}^{\delta}$-martingale if and only if $f\left(R_{t}, t\right) \exp \left(-\lambda\left(R_{t}^{2}-\delta t\right)\right)$ is a ${ }^{-\mu} P_{x}^{\delta}$-martingale. In other words, a function ${ }^{-\lambda} H: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$is such that

$$
\begin{equation*}
{ }^{-\lambda} H(r) \mathrm{e}^{-\alpha t} \text { is space-time harmonic with respect to the }\left(-^{-\lambda} P_{x}^{\delta}\right)_{x \geqslant 0} \text { family, } \tag{25}
\end{equation*}
$$

if and only if ${ }^{-\lambda} H(r) \mathrm{e}^{\mu r^{2}} \mathrm{e}^{-(\alpha+\delta \mu) t}$ is space-time harmonic with respect to the $\left({ }^{-\mu} P_{x}^{\delta}\right)_{x \geqslant 0}$ family. Consequently, if $F_{\beta}(r) \mathrm{e}^{-\beta t}$ is space-time harmonic with respect to $\left({ }^{-\mu} P_{x}^{\delta}\right)_{x \geqslant 0}$, then

$$
{ }^{-\lambda} H_{\alpha}(r)=F_{(\alpha+\delta \mu) / 2 \mu}(r) \mathrm{e}^{-\mu r^{2}}
$$

satisfies (25). Now, Theorems 3 and 4 follow from Theorems 1 and 2 applied with the parameter $\mu(=-\lambda)>0$.

Remark 5. We mention another approach to obtain results concerning first hitting times of radial Ornstein-Uhlenbeck processes. Consider a $\delta$-dimensional radial Ornstein-Uhlenbeck process $\left(R_{t}\right)$, starting at $x>0, \delta<2$. We are interested in $T_{y}=\inf \left\{t \mid R_{t}=y\right\}, x>y \geqslant 0$. By analogy with the case of BES processes in Section 2.1 we consider the process $\left(R_{t}\right)$ timereversed, starting at $T_{0}=\inf \left\{t \mid R_{t}=0\right\}$; see Appendix B. Denote the time-reversed process by ( $\hat{R}_{t}$ ). With the same notation as in (16), we are interested in $\hat{L}_{x \rightarrow y}$, i.e., in the process ( $\hat{R}_{t}$ ) after $\hat{L}_{0 \rightarrow y}$. By using the technique of enlargement of filtration, we can write ( $\hat{R}_{t}$ ) after $\hat{L}_{0 \rightarrow y}$ as a diffusion. For a treatment see, for example, Jeulin (1980) and Yor (1997, §12). Heuristically speaking, we enlarge the original filtration progressively, so that the last exit time $\hat{L}_{0 \rightarrow y}$ becomes a stopping time. Applying Yor (1997, Theorem 12.4), we obtain:

Proposition 2. For the diffusion process $\tilde{R}_{u} \equiv \hat{R}_{\left(\hat{L}_{0 \rightarrow y}+u\right)}$ we have

$$
\begin{equation*}
\tilde{R}_{u}=y+\int_{0}^{u} b\left(\tilde{R}_{v}\right) \mathrm{d} v-\int_{0}^{u} \frac{s^{\prime}\left(\tilde{R}_{v}\right)}{s(y)-s\left(\tilde{R}_{v}\right)} 1_{\left(\tilde{R}_{v}>y\right)} \mathrm{d} v+\tilde{W}_{u} \tag{26}
\end{equation*}
$$

where $u \geqslant 0, b$ is the drift and $s$ is the scale function of the transient diffusion $\hat{R}$.
As an illustration, consider the process $\hat{R}$ to be a transient BES process $\hat{X}$, that is, a BES process with index $v>0$, starting at 0 . Its scale function may be chosen as $s(x)=-x^{-2 v}$, and we obtain from (26),

$$
\begin{equation*}
\tilde{X}_{u} \equiv \hat{X}_{\left(\hat{L}_{0 \rightarrow y}+u\right)}=y+\int_{0}^{u} \frac{1}{\tilde{X}_{v}} \frac{(v+1 / 2) \tilde{X}_{v}^{2 v}+(v-1 / 2) y^{2 v}}{\tilde{X}_{v}^{2 v}-y^{2 v}} \mathrm{~d} v+\tilde{W}_{u} \tag{27}
\end{equation*}
$$

For a $\operatorname{BES}^{3}(0)$ process $\hat{X}$, (27) reduces to

$$
\tilde{X}_{u} \equiv \hat{X}_{\left(\hat{L}_{0 \rightarrow y}+u\right)}=y+\int_{0}^{u} \frac{\mathrm{~d} v}{\tilde{X}_{v}-y}+\tilde{W}_{u}
$$

Hence, for a $\operatorname{BES}^{3}(0)$ process $X$, we have

$$
\left(X_{L_{y}+u}-y, u \geqslant 0\right) \stackrel{(\text { law })}{=}\left(X_{u}, u \geqslant 0\right)
$$

In general, the transition density $\tilde{p}$ of the diffusion $\tilde{R}$ in (26) is unknown. Note that if it were known, we would obtain the density of the last hitting time of $x$ by the process $\tilde{R}$ immediately from the formula

$$
P_{y}\left(\tilde{L}_{x} \in d t\right)=-\frac{1}{2 s(x)} \tilde{p}_{t}(y, x) \mathrm{d} t
$$

(see Borodin and Salminen 2002, IV.44, p. 75; Revuz and Yor 1999, Chapter 7, (4.16)), where $\tilde{R}_{0}=y$ and $s$ is the scale function of $\tilde{R}$ with $\lim _{a \downarrow 0} s(a)=-\infty$ and $s(\infty)=0$.

Remark 6. As indicated at the end of Section 1, we are interested in the resolvent of radial Ornstein-Uhlenbeck processes. We obtain for the resolvent (see (6)) with $f(r) \equiv(r-k)^{+}$,

$$
\mathrm{E}_{x}\left[\int_{0}^{\infty} \mathrm{e}^{-\alpha t} f\left(R_{t}\right) \mathrm{d} t\right]=\int_{0}^{\infty} f(r) \int_{0}^{\infty} \mathrm{e}^{-\alpha t} p_{t}(x, r) \mathrm{d} t \mathrm{~d} r
$$

with $p_{t}$ the transition density of $R_{t}$, leaving us with the computation of $\int_{0}^{\infty} \mathrm{e}^{-\alpha t} p_{t}(x, y) \mathrm{d} t$. First, we consider $\mathrm{BES}_{x}^{\delta}$ processes and obtain, with Section A.2,

$$
\int_{0}^{\infty} \mathrm{e}^{-\alpha t} \frac{1}{t} y\left(\frac{y}{x}\right)^{v} \exp \left(-\frac{x^{2}+y^{2}}{2 t}\right) I_{v}\left(\frac{x y}{t}\right) \mathrm{d} t=2\left(\frac{y}{x}\right)^{v} y I_{v}\left(z_{1}\right) K_{v}\left(z_{2}\right)
$$

where

$$
z_{1}=\sqrt{2 \alpha} \min (x, y) \text { and } z_{2}=\sqrt{2 \alpha} \max (x, y)
$$

see Oberhettinger and Badii (1973, (I.1.15.55)). For a treatment of the resolvent for Bessel processes we refer to Itô and McKean (1996), and also to De Schepper et al. (1992) and Alili and Gruet (1997). Using relation (19) we obtain, for a $\delta$-dimensional radial OrnsteinUhlenbeck process with parameter $-\lambda$,

$$
\begin{aligned}
& \int_{0}^{\infty} \mathrm{e}^{-\alpha t} 2 y \lambda \frac{\mathrm{e}^{2 \lambda t}}{\mathrm{e}^{2 \lambda t}-1}\left(\frac{\mathrm{e}^{\lambda t} y}{x}\right)^{v} \exp \left(-\lambda \frac{x^{2}+\mathrm{e}^{2 \lambda t} y^{2}}{\mathrm{e}^{2 \lambda t}-1}\right) I_{\nu}\left(\frac{2 \lambda x y \mathrm{e}^{\lambda t}}{\mathrm{e}^{2 \lambda t}-1}\right) \mathrm{d} t \\
& \quad=y\left(\frac{y}{x}\right)^{v} \int_{0}^{\infty} \frac{(u+1)^{(v-\alpha / \lambda) / 2}}{u} \exp \left(-\lambda \frac{x^{2}+(u+1) y^{2}}{u}\right) I_{v}\left(\frac{2 \lambda x y \sqrt{u+1}}{u}\right) \mathrm{d} u .
\end{aligned}
$$

## 3. BESQ processes with negative dimensions and extensions

Bessel processes with non-negative dimension $\delta \geqslant 0$ and starting point $x \geqslant 0$ have been well studied; see, for example, Revuz and Yor (1999, Chapter XI). As already pointed out in Section 1, it seems to be quite natural also to consider Bessel processes with negative dimensions or negative starting points. Therefore, we are motivated to extend the definition of $\mathrm{BESQ}_{x}^{\delta}$ processes and to introduce the class of $\mathrm{BESQ}_{x}^{\delta}$ processes with arbitrary $\delta, x \in \mathbb{R}$.

Definition 3. The solution to the stochastic differential equation

$$
\begin{equation*}
\mathrm{d} X_{t}=\delta \mathrm{d} t+2 \sqrt{\left|X_{t}\right|} \mathrm{d} W_{t}, \quad X_{0}=x, \tag{28}
\end{equation*}
$$

where $\left\{W_{t}\right\}$ is a one-dimensional Brownian motion, $\delta \in \mathbb{R}$ and $x \in \mathbb{R}$, is called the square of a $\delta$-dimensional Bessel process, starting at $x$, and is denoted by $\mathrm{BESQ}_{x}^{\delta}$.

Moreover, we generalize the definition of a CIR process, that is, a squared $\delta$-dimensional radial Ornstein-Uhlenbeck process with parameter $-\lambda$ in (7), by allowing the starting point and $\delta$ to be in $\mathbb{R}$.

Definition 4. The solution to the stochastic differential equation

$$
\begin{equation*}
\mathrm{d} X_{t}=\left(\delta+2 \lambda X_{t}\right) \mathrm{d} t+2 \sqrt{\left|X_{t}\right|} \mathrm{d} W_{t}, \quad X_{0}=x, \tag{29}
\end{equation*}
$$

where $\delta, \lambda, x \in \mathbb{R}$ and $\left\{W_{t}\right\}$ is a one-dimensional Brownian motion, is called a squared $\delta$ dimensional radial Ornstein-Uhlenbeck process with parameter $\lambda$.

First, we will derive and discuss properties of $\mathrm{BESQ}_{x}^{\delta}$ processes (28) with $\delta, x \in \mathbb{R}$, and as an extension we study CIR processes (29) in Section 3.1.

As mentioned in the introduction, equation (28) is not the only possible way of defining $\mathrm{BESQ}^{\delta}$ processes with $\delta \in \mathbb{R}$. We will discuss this point after investigating the behaviour of $\mathrm{BESQ}^{\delta}$ processes with $\delta \in \mathbb{R}$ defined by (28). Equation (28) has a unique strong solution (Revuz and Yor 1999, Chapter IX, §3). Denote its law by $Q_{x}^{\delta}$. First, we wish to investigate the behaviour of a $\mathrm{BESQ}_{x}^{\delta}$ process, starting at $x>0$ with dimension $\delta \leqslant 0$. In the case $\delta=0$ the process reaches 0 in finite time and stays there. As for the case $\delta<0$, we deduce
from the comparison theorem that 0 is also reached in finite time. Let us consider the behaviour of a $\mathrm{BESQ}_{x}^{\delta}$ process $\left\{X_{t}\right\}$ with $\delta<0$ and $x>0$ after it has reached 0 ; we find

$$
\begin{equation*}
\tilde{X}_{u} \equiv X_{T_{0}+u}=\delta u+2 \int_{T_{0}}^{T_{0}+u} \sqrt{\left|X_{s}\right|} \mathrm{d} W_{s}, \quad u \geqslant 0 \tag{30}
\end{equation*}
$$

where $T_{0}=\inf \left\{t \mid X_{t}=0\right\}$ denotes the first time the process $\left\{X_{t}\right\}$ hits 0 . With the notation $\gamma \equiv-\delta$ we obtain, from (30),

$$
-\tilde{X}_{u}=\gamma u+2 \int_{0}^{u} \sqrt{\left|\tilde{X}_{s}\right|} \mathrm{d} \tilde{W}_{s}, \quad u \geqslant 0
$$

where $\tilde{W}_{s} \equiv-\left(W_{s+T_{0}}-W_{T_{0}}\right)$, that is, after the $\mathrm{BESQ}_{x}^{-\gamma}$ process $\left\{X_{t}\right\}$ hits 0 , it behaves as a $-\mathrm{BESQ}_{0}^{\gamma}$ process. Simulated paths of a $\mathrm{BES}_{x}^{-\gamma}$ process with $\gamma \geqslant 2$ and $\gamma<2$ are shown in Figures 2 and 3 , respectively.

Figure 2. Simulated path of a $\mathrm{BES}^{-\gamma}$ process with $\gamma \geqslant 2, x_{0}=5$.
From the above discussion we deduce that a $\mathrm{BESQ}_{x}^{\delta}$ process with $\delta<0$ and $x \leqslant 0$ behaves as $\left[-\mathrm{BESQ}_{-x}^{-\delta}\right]$; in particular, it never becomes positive. For a $\mathrm{BESQ}_{x}^{\delta}$ process with dimension $\delta \geqslant 0$ and starting point $x \leqslant 0$, we obtain with the same argument that it behaves as a $-\mathrm{BESQ}_{-x}^{-\delta}$ process; this means that, until it hits 0 for the first time, it behaves as a $-\mathrm{BESQ}_{-x}^{-\delta}$ process, and thereafter it behaves as a $\mathrm{BESQ}_{0}^{\delta}$ process.

Let us now pursue another way of extending Definition 1 to $\mathrm{BESQ}^{\delta}$ processes with $\delta \in \mathbb{R}$. Instead of a $\mathrm{BESQ}^{\delta}$ process in (28) with diffusion coefficient $\sigma(x)=2 \sqrt{|x|}$, we consider the process

$$
X_{t}=x_{0}-\delta t+2 \int_{0}^{t} \sqrt{\alpha X_{s}^{+}+\beta X_{s}^{-}} \mathrm{d} B_{s}
$$

where $\alpha, \beta \geqslant 0, x^{+}=\max (x, 0), x^{-}=\max (-x, 0)$ and, as before, $x_{0}>0, \delta>0$. For $t \leqslant T_{0}$, we have

Figure 3. Simulated path of a $\operatorname{BES}^{-\gamma}$ process with $\gamma<2, x_{0}=5$.

$$
\begin{equation*}
X_{t}=x_{0}-\delta t+2 \int_{0}^{t} \sqrt{\alpha X_{s}} \mathrm{~d} B_{s} \tag{31}
\end{equation*}
$$

After $T_{0}$ the process evolves as

$$
X_{T_{0}+t}=-\delta t+2 \int_{T_{0}}^{T_{0}+t} \sqrt{\alpha X_{s}^{+}+\beta X_{s}^{-}} \mathrm{d} B_{s}
$$

and with $Y_{t} \equiv-X_{T_{0}+t}$ we have

$$
Y_{t}=\delta t+2 \int_{0}^{t} \sqrt{\alpha Y_{s}^{-}+\beta Y_{s}^{+}} \mathrm{d} \tilde{B}_{s}
$$

This admits only one solution, which is the positive process

$$
\begin{equation*}
Y_{t}=\delta t+2 \int_{0}^{t} \sqrt{\beta Y_{s}} \mathrm{~d} \tilde{B}_{s} \tag{32}
\end{equation*}
$$

Note that the parameter $\beta$ in (32), as well as the parameter $\alpha$ in (31), can be thought of as coming from a time transformation of a $\mathrm{BESQ}^{\gamma}$ process $Z$

$$
Z_{t}=\gamma t+2 \int_{0}^{t} \sqrt{Z_{s}} \mathrm{~d} B_{s}
$$

since

$$
Z_{c^{2} t}=\gamma c^{2} t+2 \int_{0}^{t} \sqrt{c^{2} Z_{c^{2} s}} \mathrm{~d} \bar{B}_{s}
$$

Having made this observation let us now continue to investigate properties of processes defined by (28). An important and well-known property of squared Bessel processes with non-negative dimensions is their additivity property (see Section A.4). The additivity
property ceases to hold for $\mathrm{BESQ}^{\delta}$ processes with $\delta \in \mathbb{\sim} \mathbb{R}$ arbitrary. Consider the $\mathrm{BESQ}_{x}^{\beta}$ process $Z^{\beta}$ and the $\operatorname{BESQ}_{y}^{\tilde{\beta}}$ process $Z^{\tilde{\beta}}$, where $\beta>0, \tilde{\beta} \equiv-\gamma<0$ with $\beta \geqslant \gamma, x \geqslant 0$ and $y \leqslant 0$. Assuming that the additivity property holds would yield

$$
Z^{\beta}+Z^{\tilde{\beta}} \stackrel{\text { (law) }}{=} Z^{\beta}-Z^{\gamma} \stackrel{(\text { law })}{=} Z^{\beta-\gamma} \geqslant 0
$$

since $\beta \geqslant \gamma$, which cannot be true because of the independence of $Z^{\beta}$ and $Z^{\gamma}$. Our aim is to find the semigroup of a $\mathrm{BESQ}_{x}^{-\gamma}$ process $\left\{X_{t}\right\}$ with $\gamma \geqslant 0, x \geqslant 0$. Our result is the following:

Proposition 3. The semigroup of a $\mathrm{BESQ}_{x}^{-\gamma}$ process, $\gamma>0, x \geqslant 0$, is given by

$$
Q_{x}^{-\gamma}\left(X_{t} \in \mathrm{~d} y\right)=q_{t}^{-\gamma}(x, y) \mathrm{d} y
$$

with

$$
q_{t}^{-\gamma}(x, y)=q_{t}^{4+\gamma}(y, x) 1_{(y>0)}+\int_{0}^{t}(\gamma+2) q_{s}^{4+\gamma}(0, x) q_{t-s}^{\gamma}(0,-y) 1_{(y<0)} \mathrm{d} s
$$

Proof. We decompose the process $\left(X_{t}\right)$ before and after $T_{0}$, the time it first hits 0 ; we obtain

$$
\mathrm{E}_{x}^{-\gamma}\left[f\left(X_{t}\right)\right]=A+B
$$

where

$$
\begin{aligned}
A & =\mathrm{E}_{x}^{-\gamma}\left[f\left(X_{t}\right) 1_{\left(t<T_{0}\right)}\right], \\
B & =\mathrm{E}_{x}^{-\gamma}\left[f\left(X_{t}\right) 1_{\left(T_{0}<t\right)}\right]=\mathrm{E}_{x}^{-\gamma}\left[f\left(X_{T_{0}+\left(t-T_{0}\right)}\right) 1_{\left(T_{0}<t\right)}\right] \\
& =\int_{0}^{t} Q_{x}^{-\gamma}\left(T_{0} \in \mathrm{~d} s\right) \int_{-\infty}^{0} f(y) q_{t-s}^{\gamma}(0,-y) \mathrm{d} y,
\end{aligned}
$$

since $\left(-X_{\left(T_{0}+u\right)}, u \geqslant 0\right)$ is distributed as a $\mathrm{BESQ}_{0}^{\gamma}$ process.
We now compute $A$ with either of the following arguments:
(i) We use the absolute continuity relationship:

$$
\left.Q_{x}^{-\gamma}\right|_{\mathcal{F}_{t} \cap\left(t<T_{0}\right)}=\left.\left(\frac{X_{t}}{x}\right)^{-v} \cdot Q_{x}^{4+\gamma}\right|_{\mathcal{F}_{t}}
$$

where $4+\gamma=2(1+v)$, and we note, from formula (49), that

$$
\left(\frac{y}{x}\right)^{-v} q_{t}^{4+\gamma}(x, y)=q_{t}^{4+\gamma}(y, x)
$$

Thus, we obtain

$$
\begin{equation*}
A=\int_{0}^{\infty} f(y) q_{t}^{4+\gamma}(y, x) \mathrm{d} y \tag{33}
\end{equation*}
$$

(ii) The following time-reversal argument will confirm formula (33). First, we note

$$
\begin{align*}
\mathrm{E}_{x}^{-\gamma}\left[f\left(X_{t}\right) 1_{\left(t<T_{0}\right)}\right] & =\mathrm{E}_{0}^{4+\gamma}\left[f\left(X_{L_{x}-t}\right) 1_{\left(t<L_{x}\right)}\right] \\
& =\int_{t}^{\infty} q_{x}(s) \mathrm{E}_{0}^{4+\gamma}\left[f\left(X_{s-t}\right) \mid X_{s}=x\right] \mathrm{d} s \tag{34}
\end{align*}
$$

where $q_{x}(s) \mathrm{d} s \equiv Q_{0}^{4+\gamma}\left(L_{x} \in \mathrm{~d} s\right)$. Then standard Markovian computations show that

$$
\begin{equation*}
\mathrm{E}_{0}^{4+\gamma}\left[f\left(X_{s-t}\right) \mid X_{s}=x\right]=\int f(y) \frac{q_{s-t}^{4+\gamma}(0, y) q_{t}^{4+\gamma}(y, x)}{q_{s}^{4+\gamma}(0, x)} \mathrm{d} y \tag{35}
\end{equation*}
$$

Moreover, we find, by comparison of (15) and (50), say, that

$$
\begin{equation*}
q_{x}(s)=(2+\gamma) q_{s}^{4+\gamma}(0, x) \tag{36}
\end{equation*}
$$

Putting together (34), (35) and (36), we obtain

$$
\mathrm{E}_{x}^{-\gamma}\left[f\left(X_{t}\right) 1_{\left(t<T_{0}\right)}\right]=\int_{t}^{\infty}(2+\gamma) \int f(y) q_{s-t}^{4+\gamma}(0, y) q_{t}^{4+\gamma}(y, x) \mathrm{d} y \mathrm{~d} s
$$

Using Fubini's theorem, integrating in ( $\mathrm{d} s$ ), and using (36) with $y$ instead of $x$, we finally obtain (33).

The computation of $B$ is done with the formula $Q_{x}^{-\gamma}\left(T_{0} \in \mathrm{~d} s\right)=q_{x}(s) \mathrm{d} s$, followed by the use of formula (36), and the proof is complete.

In order to make the semigroup formula $q_{t}^{-\gamma}(x, y)$ more explicit, we need to compute

$$
\int_{0}^{t} q_{s}^{4+\gamma}(0, x) q_{t-s}^{\gamma}(0, \bar{y}) \mathrm{d} s
$$

where $\bar{y}=-y$, for $y<0$. Elementary computations yield

$$
\begin{equation*}
q_{t}^{(-\gamma)}(x, y)=k(x, y, \gamma, t) \mathrm{e}^{-\alpha-\beta} \int_{0}^{\infty} \frac{(w+1)^{2 m}}{w^{m}} \exp \left(-\beta w-\frac{\alpha}{w}\right) \mathrm{d} w \tag{37}
\end{equation*}
$$

with

$$
k(x, y, \gamma, t) \equiv \Gamma^{-2}\left(\frac{\gamma}{2}\right) \frac{2^{-\gamma}}{\gamma} x^{\gamma / 2+1}|y|^{\gamma / 2-1} t^{-\gamma-1}
$$

and

$$
m \equiv \frac{\gamma}{2}, \quad \alpha \equiv \frac{|y|}{2 t}, \quad \beta \equiv \frac{x}{2 t}
$$

We expand formula (37) for $\gamma \in \mathbb{N}$ as follows:

$$
\begin{aligned}
q_{t}^{(-\gamma)}(x, y) & =k(x, y, \gamma, t) \mathrm{e}^{-\alpha-\beta} \sum_{k=0}^{2 m}\binom{2 m}{k} \int_{0}^{\infty} w^{m-k} \exp \left(-\beta w-\frac{\alpha}{w}\right) \mathrm{d} w \\
& =k(x, y, \gamma, t) \mathrm{e}^{-\alpha-\beta} 2 \sum_{k=0}^{2 m}\binom{2 m}{k}\left(\frac{\beta}{\alpha}\right)^{(k-m-1) / 2} K_{k-m-1}(2 \sqrt{\alpha \beta}),
\end{aligned}
$$

where $K_{v}(z)$ denotes the Macdonald function with index $v$ (see (17)), taken from Lebedev (1972, (5.10.25)).
As a test of our above description of the law $Q_{x}^{-\gamma}$ of a $\mathrm{BESQ}_{x}^{-\gamma}$ process $\left(Z_{t}\right)_{t \geqslant 0}$ with $\gamma, x>0$, we now present some computations involving linear functionals of this process; see also Revuz and Yor (1999, Chapter XI, Exercise (1.34)), and, for an improvement of this exercise, Föllmer et al. (1999). Since $\left(-Z_{T_{0}+t}, t \geqslant 0\right)$ is a $\mathrm{BESQ}_{0}^{\gamma}$ process, independent of the past of $\left(Z_{t}\right)$ up to $T_{0}$, we have

$$
\begin{aligned}
Q_{x}^{-\gamma}\left[\exp \left(-\int_{0}^{\infty} Z_{u} f(u) \mathrm{d} u\right)\right]= & \int_{0}^{\infty} Q_{x}^{-\gamma}\left[\exp \left(-\int_{0}^{t} Z_{u} f(u) \mathrm{d} u\right) \mid T_{0}=t\right] \\
& \times Q_{0}^{\gamma}\left[\exp \left(\int_{0}^{\infty} X_{v} f(t+v) \mathrm{d} u\right)\right] Q_{x}^{-\gamma}\left[T_{0} \in \mathrm{~d} t\right]
\end{aligned}
$$

with a $\mathrm{BESQ}_{0}^{\gamma}$ process $\left(X_{v}\right)_{v \geqslant 0}$ and a positive Borel function $f$. In the following, negativedimensional BESQ processes are denoted by $\left(Z_{t}\right)$ and positive-dimensional ones by $\left(X_{t}\right)$. We obtain

$$
Q_{x}^{-\gamma}\left[\exp \left(-\int_{0}^{t} Z_{u} f(u) \mathrm{d} u\right) \mid T_{0}=t\right]=Q_{0}^{4+\gamma}\left[\exp \left(-\int_{0}^{t} X_{u} f(t-u) \mathrm{d} u\right) \mid L_{x}=t\right],
$$

and, with the equalities

$$
\begin{aligned}
Q_{0}^{4+\gamma}\left[\exp \left(-\int_{0}^{t} X_{u} f(t-u) \mathrm{d} u\right) \mid L_{x}=t\right] & =Q_{0}^{4+\gamma}\left[\exp \left(-\int_{0}^{t} X_{u} f(t-u) \mathrm{d} u\right) \mid X_{t}=x\right] \\
& =Q_{x}^{4+\gamma}\left[\exp \left(-\int_{0}^{t} X_{t-u} f(t-u) \mathrm{d} u\right) \mid X_{t}=0\right] \\
& =Q_{x}^{4+\gamma}\left[\exp \left(-\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right) \mid X_{t}=0\right],
\end{aligned}
$$

we finally have

$$
\begin{align*}
Q_{x}^{-\gamma}\left[\exp \left(-\int_{0}^{\infty} Z_{u} f(u) \mathrm{d} u\right)\right]= & \int_{0}^{\infty} Q_{x}^{4+\gamma}\left[\exp \left(-\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right) \mid X_{t}=0\right] \\
& \times Q_{0}^{\gamma}\left[\exp \left(\int_{0}^{\infty} X_{v} f(t+v) \mathrm{d} v\right)\right] q_{x}(t) \mathrm{d} t \tag{38}
\end{align*}
$$

Our aim is to determine

$$
Q_{x}^{4+\gamma}\left[\exp \left(-\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right) \mid X_{t}=0\right]
$$

and

$$
Q_{0}^{y}\left[\exp \left(\int_{0}^{\infty} X_{v} f(t+v) \mathrm{d} v\right)\right]
$$

more explicitly. Using the well-known fact that, for a function $h: \mathbb{R}^{+} \rightarrow \mathbb{R}$ in $L^{1}$ with $h(x) \leqslant c$ for all $x \in \mathbb{R}^{+}$and continuous in a neighbourhood of 0 ,

$$
\lim _{\lambda \rightarrow \infty} \int_{0}^{\infty} \lambda \mathrm{e}^{-\lambda y} h(y) \mathrm{d} y=h(0)
$$

we deduce that the ratio

$$
\begin{equation*}
\frac{Q_{x}^{\delta}\left(\exp \left(-\lambda X_{t}-\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right)\right)}{Q_{x}^{\delta}\left(\exp \left(-\lambda X_{t}\right)\right)}=\frac{\int_{0}^{\infty} \mathrm{e}^{-\lambda y} q_{t}^{\delta}(x, y) Q_{x}^{\delta}\left(\exp \left(-\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right) \mid X_{t}=y\right) \mathrm{d} y}{\int_{0}^{\infty} \mathrm{e}^{-\lambda y} q_{t}^{\delta}(x, y) \mathrm{d} y} \tag{39}
\end{equation*}
$$

as $\lambda$ tends to infinity, converges to

$$
Q_{x}^{\delta}\left(\exp \left(-\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right) \mid X_{t}=0\right)
$$

Let us consider the numerator and denominator of ratio (39) separately. From Pitman and Yor (1982b, formula (1.h)), and Revuz and Yor (1999, Chapter XI, Theorem (1.7)) we have:

Lemma 1. Consider a positive function $f: \mathbb{R}^{+} \rightarrow \mathbb{R}^{+}$with $\int_{0}^{n} f(s) \mathrm{d} s<\infty$ for all $n$. Then $Q_{x}^{\delta}\left[\exp \left(-\int_{0}^{t} X_{u} f(u) \mathrm{d} u-\frac{\lambda}{2} X_{t}\right)\right]$

$$
\begin{equation*}
=\left(\psi_{f}^{\prime}(t)+\lambda \psi_{f}(t)\right)^{-\delta / 2} \exp \left(\frac{x}{2}\left[\phi_{f}^{\prime}(0)-\frac{\left(\phi_{f}^{\prime}+\lambda \phi_{f}\right)(t)}{\left(\psi_{f}^{\prime}+\lambda \psi_{f}\right)(t)}\right]\right) \tag{40}
\end{equation*}
$$

where $\phi_{f}$ is the unique solution of the Sturm-Liouville equation

$$
\frac{1}{2} \phi_{f}^{\prime \prime}(s)=f(s) \phi_{f}(s)
$$

with $s \in(0, \infty), \quad \phi_{f}(0)=1$, which is positive and non-increasing, $\phi_{f}^{\prime}(0)$ is the right derivative in 0 , and

$$
\psi_{f}(t) \equiv \phi_{f}(t) \int_{0}^{t} \frac{\mathrm{~d} s}{\phi_{f}^{2}(s)}
$$

Furthermore,

$$
\begin{equation*}
Q_{x}^{\delta}\left(\exp \left(-\int_{0}^{\infty} X_{u} f(u) \mathrm{d} u\right)\right)=\phi_{f}(\infty)^{\delta / 2} \exp \left(\frac{x}{2} \phi_{f}^{\prime}(0)\right) \tag{41}
\end{equation*}
$$

where $\phi_{f}(\infty) \in[0,1]$ is the limit at infinity of $\phi_{f}(s)$.
From the formula following Corollary (XI.1.3) in Revuz and Yor (1999) we know that

$$
Q_{x}^{\delta}\left(\exp \left(-\frac{\lambda}{2} X_{t}\right)\right)=(1+\lambda t)^{-\delta / 2} \exp \left(\frac{-\lambda x / 2}{1+\lambda t}\right)
$$

and, together with (40), we obtain

$$
\begin{equation*}
Q_{x}^{\delta}\left(\exp \left(-\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right) \mid X_{t}=0\right)=\left(\frac{t}{\psi_{f}(t)}\right)^{\delta / 2} \exp \left(\frac{x}{2}\left(\phi_{f}^{\prime}(0)-\frac{\phi_{f}(t)}{\psi_{f}(t)}+\frac{1}{t}\right)\right) \tag{42}
\end{equation*}
$$

We now determine $Q_{x}^{\delta}\left(\exp \left( \pm \int_{0}^{\infty} X_{s} f(t+s) \mathrm{d} s\right)\right)$ more explicitly. Note that the function

$$
\phi_{t}(s) \equiv \frac{\phi_{f}(t+s)}{\phi_{f}(t)}
$$

solves

$$
\frac{1}{2} \phi_{t}^{\prime \prime}(s)=f(t+s) \phi_{t}(s)
$$

and that formula (41) leads to

$$
\begin{aligned}
Q_{x}^{\delta}\left(\exp \left(-\int_{0}^{\infty} X_{s} f(t+s) \mathrm{d} s\right)\right) & =\phi_{t}(\infty)^{\delta / 2} \exp \left(\frac{x}{2} \phi_{t}^{\prime}(0)\right) \\
& =\left(\frac{\phi_{f}(\infty)}{\phi_{f}(t)}\right)^{\delta / 2} \exp \left(\frac{x}{2} \frac{\phi_{f}^{\prime}(t)}{\phi_{f}(t)}\right)
\end{aligned}
$$

Lemma 2. For a positive decreasing function $f: \mathbb{R}^{+} \rightarrow \mathbb{R}^{+}$, such that

$$
\begin{equation*}
Q_{x}^{\delta}\left(\exp \left(\int_{0}^{\infty} X_{s} f(s) \mathrm{d} s\right)\right)<\infty \tag{43}
\end{equation*}
$$

there exists a function $\tilde{\phi}$ which is the unique solution on $(0, \infty)$ of

$$
\frac{1}{2} \tilde{\phi}^{\prime \prime}(s)=-f(s) \tilde{\phi}(s)
$$

with $\tilde{\phi}(0)=1$ such that

$$
Q_{x}^{\delta}\left(\exp \left(\int_{0}^{\infty} X_{u} f(t+u) \mathrm{d} u\right)\right)=\left(\frac{\tilde{\phi}(\infty)}{\tilde{\phi}(t)}\right)^{\delta / 2} \exp \left(\frac{x}{2} \frac{\tilde{\phi}^{\prime}(t)}{\tilde{\phi}(t)}\right)
$$

Proof. Concerning verifications of condition (43), we refer to McGill (1981). We wish to determine functions $\alpha(t)$ and $\beta(t)$ with

$$
\begin{equation*}
Q_{x}^{\delta}\left(\exp \left(\int_{0}^{\infty} X_{u} f(t+u) \mathrm{d} u\right)\right)=(\beta(t))^{\delta / 2} \exp (x \alpha(t)) \tag{44}
\end{equation*}
$$

Using the Markov property, we have

$$
Q_{x}^{\delta}\left(\exp \left(\int_{0}^{\infty} X_{u} f(u) \mathrm{d} u\right) \mid \mathcal{F}_{t}\right)=\exp \left(\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right) Q_{X_{t}}^{\delta}\left(\exp \left(\int_{0}^{\infty} X_{u} f(t+u) \mathrm{d} u\right)\right)
$$

Denote

$$
h(x, t ; \omega) \equiv(\beta(t))^{\delta / 2} \exp (x \alpha(t)) \exp \left(\int_{0}^{t} X_{u} f(u) \mathrm{d} u\right)
$$

Since $Q_{x}^{\delta}\left(\exp \int_{0}^{\infty} X_{u} f(u) \mathrm{d} u \mid \mathcal{F}_{t}\right)$ is a martingale, we see using Itô's formula that the functions $\alpha$ and $\beta$ have to fulfil the following condition in terms of $h$ :

$$
\frac{\partial}{\partial t} h(x, t)+2 x \frac{\partial^{2}}{\partial x^{2}} h(x, t)+\delta \frac{\partial}{\partial x} h(x, t)=0
$$

This implies

$$
\alpha^{\prime}(t)+f(t)+2 \alpha^{2}(t)=0, \quad \alpha(t)+\frac{\beta^{\prime}(t)}{2 \beta(t)}=0
$$

Hence,

$$
\alpha(t)=-\frac{\beta^{\prime}(t)}{2 \beta(t)}, \quad f(t)=\frac{\beta^{\prime \prime}(t)}{2 \beta(t)}-\left(\frac{\beta^{\prime}(t)}{\beta(t)}\right)^{2}
$$

Consider the function $\tilde{\phi}: \mathbb{R}^{+} \rightarrow \mathbb{R}^{+}$, with

$$
\tilde{\phi}(s) \equiv \frac{\beta(0)}{\beta(s)}
$$

Then $\tilde{\phi}$ is the unique solution on $(0, \infty)$ of

$$
\frac{1}{2} \tilde{\phi}^{\prime \prime}(t)=-f(t) \tilde{\phi}(t)
$$

with $\tilde{\phi}(0)=1$. We obtain

$$
\alpha(t)=\frac{\tilde{\phi}^{\prime}(t)}{2 \tilde{\phi}(t)}
$$

From (44) we deduce by dominated convergence that $\lim _{t \rightarrow \infty} \beta(t)=1$, and hence $\tilde{\phi}(\infty) \equiv \lim _{t \rightarrow \infty} \tilde{\phi}(t)=\beta(0)$.

Altogether we obtain, for (38) with (42) and Lemma 2:

## Theorem 5.

$$
\begin{aligned}
Q_{x}^{-\gamma}\left(\exp \left(-\int_{0}^{\infty} Z_{u} f(u) \mathrm{d} u\right)\right)= & \frac{1}{\Gamma(\gamma / 2+1)}\left(\frac{x}{2}\right)^{\gamma / 2+1} \\
& \times \int_{0}^{\infty}\left(\frac{1}{\psi_{f}(t)}\right)^{\gamma / 2+2}\left(\frac{\tilde{\phi}(\infty)}{\tilde{\phi}(t)}\right)^{\gamma / 2} \exp \left(\frac{x}{2}\left(\phi_{f}^{\prime}(0)-\frac{\phi_{f}(t)}{\psi_{f}(t)}\right)\right) \mathrm{d} t
\end{aligned}
$$

with $\phi_{f}$ and $\psi_{f}$ from Lemma 1, and $\tilde{\phi}$ from Lemma 2.
Example. Consider

$$
f(u) \equiv \frac{\lambda^{2}}{2} 1_{[0, a]}(u), \quad a, \lambda>0
$$

We know (Pitman and Yor 1982a, p. 432, (2.m)) that

$$
Q_{x}^{4+\gamma}\left(\left.\exp \left(-\frac{\lambda^{2}}{2} \int_{0}^{t} X_{u} \mathrm{~d} u\right) \right\rvert\, X_{t}=0\right)=\left(\frac{\lambda t}{\sinh (\lambda t)}\right)^{(4+\gamma) / 2} \exp \left(-\frac{x}{2 t}(\lambda t \operatorname{coth}(\lambda t)-1)\right)
$$

and hence we have

$$
\begin{aligned}
Q_{x}^{-\gamma}\left(\exp \left(-\frac{\lambda^{2}}{2} \int_{0}^{a} Z_{t} \mathrm{~d} t\right)\right)= & \int_{0}^{a}\left(\frac{\lambda t}{\sinh (\lambda t)}\right)^{(4+\gamma) / 2} \exp \left(-\frac{x}{2 t}(\lambda t \operatorname{coth}(\lambda t)-1)\right) \\
& \times Q_{0}^{\gamma}\left(\exp \left(\frac{\lambda^{2}}{2} \int_{0}^{a-t} X_{v} \mathrm{~d} v\right)\right) q_{x}(t) \mathrm{d} t \\
& +\int_{a}^{\infty} Q_{x}^{4+\gamma}\left(\left.\exp \left(-\frac{\lambda^{2}}{2} \int_{0}^{a} X_{u} \mathrm{~d} u\right) \right\rvert\, X_{t}=0\right) q_{x}(t) \mathrm{d} t
\end{aligned}
$$

We investigate more deeply

$$
Q_{\substack{(t)}}^{4+\gamma}\left(\exp \left(-\frac{\lambda^{2}}{2} \int_{0}^{a} X_{u} \mathrm{~d} u\right)\right) \equiv Q_{x}^{4+\gamma}\left(\left.\exp \left(-\frac{\lambda^{2}}{2} \int_{0}^{a} X_{u} \mathrm{~d} u\right) \right\rvert\, X_{t}=0\right)
$$

where a continuous process with law $Q_{\substack{x \rightarrow 0}}^{4+y}$ is called the squared Bessel bridge from $x$ to 0 over $[0, t]$; see, for example, Revuz and Yor (1999, Chapter XI, §3). For $\mathcal{A} \in \mathcal{F}_{\mathrm{a}}$ we have

$$
\begin{aligned}
Q_{x \rightarrow 0}^{4+\gamma}(\mathcal{A}) & =\lim _{y \downarrow 0} \frac{\mathrm{E}_{x}^{4+\gamma}\left(1_{\mathcal{A}} 1_{[0, y]}\left(X_{t}\right)\right)}{Q_{x}^{4+\gamma}\left(X_{t} \in[0, y]\right)} \\
& =\lim _{y \downarrow 0} \frac{\mathrm{E}_{x}^{4+\gamma}\left(1_{\mathcal{A}} \mathrm{E}_{x}^{4+\gamma}\left(1_{[0, y]}\left(X_{t}\right) \mid \mathcal{F}_{a}\right)\right)}{Q_{x}^{4+\gamma}\left(X_{t} \in[0, y]\right)} \\
& =\lim _{y \downarrow 0} \mathrm{E}_{x}^{4+\gamma}\left(1_{\mathcal{A}} \frac{Q_{X_{a}}^{4+\gamma}\left(X_{t-a} \in[0, y]\right)}{Q_{x}^{4+\gamma}\left(X_{t} \in[0, y]\right)}\right)
\end{aligned}
$$

and

$$
\lim _{y \downarrow 0} \frac{Q_{X_{a}}^{4+\gamma}\left(X_{t-a} \in[0, y]\right)}{Q_{x}^{4+\gamma}\left(X_{t} \in[0, y]\right)}=\frac{q_{t-a}^{4+\gamma}\left(X_{a}, 0\right)}{q_{t}^{4+\gamma}(x, 0)} \equiv \psi\left(a, X_{a}\right),
$$

where $q_{t}^{\delta}(x, y)$ is the transition density of $\mathrm{BESQ}^{\delta}, \delta>0$. From Yor (1995) (proof of the theorem in 0.5 ) we obtain

$$
\lim _{y\rfloor 0} \frac{q_{t-a}^{4+\gamma}\left(X_{a}, y\right)}{q_{t}^{4+\gamma}(x, y)}=\left(\frac{t}{t-a}\right)^{(4+\gamma) / 2} \exp \left(-\frac{X_{a}}{2(t-a)}\right) \exp \left(\frac{x}{2 t}\right)
$$

Formula (2.k) in Pitman and Yor (1982a) gives us

$$
\begin{aligned}
& Q_{x}^{4+\gamma}\left(\exp \left(-\frac{X_{a}}{2(t-a)}-\frac{\lambda^{2}}{2} \int_{0}^{a} X_{u} \mathrm{~d} u\right)\right) \\
& \quad=\left(\cosh (\lambda a)+\frac{1}{\lambda(t-a)} \sinh (\lambda a)\right)^{-(4+\gamma) / 2} \exp \left(-\frac{\lambda x}{2} \cdot \frac{1+\operatorname{coth}(\lambda a) /(\lambda(t-a))}{\operatorname{coth}(\lambda a)+1 /(\lambda(t-a))}\right)
\end{aligned}
$$

Hence, we have

$$
\begin{aligned}
Q_{\substack{(t)}}^{4+\gamma}\left(\exp \left(-\frac{\lambda^{2}}{2} \int_{0}^{a} X_{u} \mathrm{~d} u\right)\right)= & \left(\left(\frac{t-a}{t}\right) \cosh (\lambda a)+\frac{1}{\lambda t} \sinh (\lambda a)\right)^{-(4+\gamma) / 2} \\
& \times \exp \left(\frac{x}{2 t}-\frac{\lambda x}{2} \frac{1+\operatorname{coth}(\lambda a) /(\lambda(t-a))}{\operatorname{coth}(\lambda a)+1 /(\lambda(t-a))}\right)
\end{aligned}
$$

If, in addition, $\lambda(a-t)<\pi / 2$, we obtain

$$
Q_{0}^{\gamma}\left(\exp \left(\frac{\lambda^{2}}{2} \int_{0}^{a-t} X_{v} \mathrm{~d} v\right)\right)=\cos (\lambda(a-t))^{-\gamma / 2}
$$

and finally,

$$
\begin{aligned}
Q_{x}^{-\gamma}(\exp ( & \left.\left.-\frac{\lambda^{2}}{2} \int_{0}^{a} Z_{t} \mathrm{~d} t\right)\right) \\
= & \frac{1}{\Gamma(\gamma / 2+1)}\left(\frac{x}{2}\right)^{\gamma / 2+1}\left[\lambda^{\gamma / 2+2} \int_{0}^{a} \exp \left(-\frac{x}{2} \lambda \operatorname{coth}(\lambda t)\right) \frac{\cos (\lambda(a-t))^{-\gamma / 2}}{\sinh (\lambda t)^{\gamma / 2+2}} \mathrm{~d} t\right. \\
& \left.+\int_{0}^{\infty}\left[\cosh (\lambda a) u+\frac{1}{\lambda} \sinh (\lambda a)\right]^{-\gamma / 2-2} \exp \left(-\frac{\lambda x}{2} \frac{\lambda u+\operatorname{coth}(\lambda a)}{\lambda \operatorname{coth}(\lambda a) u+1}\right) \mathrm{d} u\right]
\end{aligned}
$$

### 3.1. Extension to squared radial Ornstein-Uhlenbeck processes

As an extension to $\mathrm{BESQ}_{x}^{\delta}$ processes in (28) with $\delta, x \in \mathbb{R}$, we now investigate squared $\delta$ dimensional radial Ornstein-Uhlenbeck processes (CIR processes), defined by (29) with $\delta, x \in \mathbb{R}$. We consider the case $\delta<0$ and $x>0$; for $\lambda=0$, this corresponds to a $\mathrm{BESQ}_{x}^{\delta}$ process with negative dimension $\delta$. We call ${ }^{\lambda} Q_{x}^{\delta}$ the law on $C\left(\mathbb{R}_{+}, \mathbb{R}\right)$ and, as before, we write $Q_{x}^{\delta} \equiv{ }^{0} Q_{x}^{\delta}$. Via Girsanov transformation we obtain the relationship

$$
\begin{equation*}
\left.{ }^{\lambda} Q_{x}^{\delta}\right|_{\mathcal{F}_{t}}=\left.\exp \left(\lambda \int_{0}^{t} \sqrt{\left|X_{s}\right|} \operatorname{sgn}\left(X_{s}\right) \mathrm{d} W_{s}-\frac{\lambda^{2}}{2} \int_{0}^{t}\left|X_{s}\right| \mathrm{d} s\right) Q_{x}^{\delta}\right|_{\mathcal{F}_{t}} \tag{45}
\end{equation*}
$$

Note that because no explosion occurs on either side of this formula, the density is a true martingale. We may also write the stochastic integral $\int_{0}^{t} \operatorname{sgn}\left(X_{s}\right) \sqrt{\left|X_{s}\right|} \mathrm{d} W_{s}$ in a simpler form, since we have from Itô's formula

$$
\left|X_{t}\right|=|x|+\int_{0}^{t} \operatorname{sgn}\left(X_{s}\right)\left(\delta \mathrm{d} s+2 \sqrt{\left|X_{s}\right|} \mathrm{d} W_{s}\right)+L_{t}^{0}(X)
$$

where $L_{t}^{0}(X)$ is the semimartingale local time of $X$ in 0 . For $L_{t}^{0}(X)$ we obtain, from Revuz and Yor (1999, Chapter VI, Corollary (1.9)),

$$
\begin{aligned}
L_{t}^{0}(X) & =\lim _{\varepsilon \downarrow 0} \frac{1}{\varepsilon} \int_{0}^{t} 1_{[0, \varepsilon]}\left(X_{s}\right) \mathrm{d}\langle X, X\rangle_{s}=\lim _{\varepsilon \downarrow 0} \frac{4}{\varepsilon} \int_{0}^{t}\left|X_{S}\right| 1_{[0, \varepsilon]}\left(X_{s}\right) \mathrm{d} s \\
& \leqslant \lim _{\varepsilon \downarrow 0}\left(4 \int_{0}^{t} 1_{[0, \varepsilon]}\left(X_{s}\right) \mathrm{d} s\right)=0
\end{aligned}
$$

Hence, we have

$$
\int_{0}^{t} \operatorname{sgn}\left(X_{s}\right) \sqrt{\left|X_{s}\right|} \mathrm{d} W_{s}=\frac{1}{2}\left(\left|X_{t}\right|-|x|-\delta \int_{0}^{t} \operatorname{sgn}\left(X_{s}\right) \mathrm{d} s\right)
$$

Thus, (45) takes the form given in the following lemma.

## Lemma 3.

$$
\left.\left.{ }^{\lambda} Q_{x}^{\delta}\right|_{\mathcal{F}_{t}} \equiv \exp \left(\frac{\lambda}{2}\left(\left|X_{t}\right|-|x|-\delta \int_{0}^{t} \operatorname{sgn}\left(X_{s}\right) \mathrm{d} s\right)-\frac{\lambda^{2}}{2} \int_{0}^{t}\left|X_{s}\right| \mathrm{d} s\right) Q_{x}^{\delta}\right|_{\mathcal{F}_{t}}
$$

Applying Lemma 3, we obtain the conditional expectation formula

$$
\begin{align*}
{ }^{\lambda} q_{t}^{\delta}(x, y)= & q_{t}^{\delta}(x, y) \exp \left(\frac{\lambda}{2}(|y|-|x|)\right) \\
& \times Q_{x}^{\delta}\left(\left.\exp \left(-\frac{\delta \lambda}{2} \int_{0}^{t} \operatorname{sgn}\left(X_{s}\right) \mathrm{d} s-\frac{\lambda^{2}}{2} \int_{0}^{t}\left|X_{s}\right| \mathrm{d} s\right) \right\rvert\, X_{t}=y\right) \tag{46}
\end{align*}
$$

where $q_{t}^{\delta}$ denotes the semigroup density in $y$ of a $\mathrm{BESQ}^{\delta}$ process, $\delta<0$, given by (37).
Using the time-space transformation from a $\mathrm{BESQ}^{\delta}$ process $\left(X_{t}^{\delta}\right)$ to a squared radial Ornstein-Uhlenbeck process $\left({ }^{\lambda} X_{t}^{\delta}\right)$,

$$
{ }^{\lambda} X_{t}^{\delta}=\mathrm{e}^{2 \lambda t} X_{\left(1-\mathrm{e}^{-2 \lambda t}\right) / 2 \lambda}^{\delta}
$$

we also have, together with the relationship (46),

$$
{ }^{\lambda} q_{t}^{\delta}(x, y)=\mathrm{e}^{-2 \lambda t} q_{\left(1-\mathrm{e}^{-2 \lambda t}\right) / 2 \lambda}^{\delta}\left(x, \mathrm{e}^{-2 \lambda t} y\right)
$$

from which ${ }^{\lambda} q_{t}^{\delta}(x, y)$ is obtained since $q_{t}^{\delta}(x, y)$ is known; see (37). Hence, we obtain from (46) the following theorem.

Theorem 6. We have

$$
\begin{aligned}
& Q_{x}^{\delta}\left(\left.\exp \left(-\frac{\delta \lambda}{2} \int_{0}^{t} \operatorname{sgn}\left(X_{s}\right) \mathrm{d} s-\frac{\lambda^{2}}{2} \int_{0}^{t}\left|X_{s}\right| \mathrm{d} s\right) \right\rvert\, X_{t}=y\right) \\
&=q_{\left(1-\mathrm{e}^{-2 \lambda t}\right) / 2 \lambda}^{\delta}\left(x, \mathrm{e}^{-2 \lambda t} y\right) \exp \left(-2 \lambda t-\frac{\lambda}{2}(|y|-|x|)\right) / q_{t}^{\delta}(x, y),
\end{aligned}
$$

with $q_{t}^{\delta}(x, y)$ given by (37).

## Appendix A. Some properties of Bessel processes

## A.1. Explicit expressions

In addition to Definitions 1 and 2, we give explicit expressions for Bessel processes. For $\delta>1$, a $\mathrm{BES}_{x_{0}}^{\delta}$ process $X_{t}$ satisfies $\mathrm{E}\left[\int_{0}^{t}\left(\mathrm{~d} s / X_{s}\right)\right]<\infty$ and is the solution to the equation

$$
\begin{equation*}
X_{t}=x_{0}+\frac{\delta-1}{2} \int_{0}^{t} \frac{\mathrm{~d} s}{X_{s}}+W_{t} \tag{47}
\end{equation*}
$$

For $\delta \leqslant 1$, the situation is less simple. For $\delta=1$, the role of (47) is played by

$$
X_{t}=\left|W_{t}\right|=\tilde{W}_{t}+L_{t}
$$

where $\tilde{W}_{t} \equiv \int_{0}^{t} \operatorname{sgn}\left(W_{s}\right) \mathrm{d} W_{s}$ is standard Brownian motion, and $L_{t}$ is the local time of Brownian motion. For a treatment of local times see, for example, Revuz and Yor (1999, Chapter VI). For $\delta<1$, we have

$$
\begin{equation*}
X_{t}=x_{0}+\frac{\delta-1}{2} \text { p.v. } \int_{0}^{t} \frac{\mathrm{~d} s}{X_{s}}+W_{t} \tag{48}
\end{equation*}
$$

where the principal value is defined as

$$
\text { p.v. } \int_{0}^{t} \frac{\mathrm{~d} s}{X_{s}} \equiv \int_{0}^{\infty} x^{\delta-2}\left(L_{t}^{x}-L_{t}^{0}\right) \mathrm{d} x
$$

and the family of local times $\left(L_{t}^{x}, x \geqslant 0\right)$ is defined as

$$
\int_{0}^{t} \varphi\left(X_{s}\right) \mathrm{d} s=\int_{0}^{\infty} \varphi(x) L_{t}^{x} x^{\delta-1} \mathrm{~d} x
$$

for all Borel functions $\varphi: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$; see Bertoin (1990). The decomposition (48) was obtained using the fact that a power of a Bessel process is another Bessel process time changed:

$$
q X_{v}^{1 / q}(t)=X_{v q}\left(\int_{0}^{t} \frac{\mathrm{~d} s}{X_{v}^{2 / p}(s)}\right)
$$

where $1 / p+1 / q=1, \quad v>-1 / q$; see, for example, Revuz and Yor (1999, Chapter XI, Proposition (1.11)).

## A.2. Transition densities

(Squared) Bessel processes are Markov processes, and their transition densities are known explicitly. For $\delta>0$, the transition density for $\mathrm{BESQ}^{\delta}$ is equal to

$$
\begin{equation*}
q_{t}^{\delta}(x, y)=\frac{1}{2 t}\left(\frac{y}{x}\right)^{v / 2} \exp \left\{-\frac{x+y}{2 t}\right\} I_{v}\left(\frac{\sqrt{x y}}{t}\right) \tag{49}
\end{equation*}
$$

where $t>0, x>0, v \equiv \delta / 2-1$ and $I_{v}$ is the modified Bessel function of the first kind of index $v$. For $x=0$, we have

$$
\begin{equation*}
q_{t}^{\delta}(0, y)=(2 t)^{-\delta / 2} \Gamma(\delta / 2)^{-1} y^{\delta / 2-1} \exp \left\{-\frac{y}{2 t}\right\} \tag{50}
\end{equation*}
$$

For the case $\delta=0$, the semigroup of $\mathrm{BESQ}^{0}$ is equal to

$$
\begin{equation*}
Q_{t}^{0}(x, \cdot)=\exp \left\{-\frac{x}{2 t}\right\} \varepsilon_{0}+\tilde{Q}_{t}(x, \cdot) \tag{51}
\end{equation*}
$$

where $\varepsilon_{0}$ is the Dirac measure in 0 and $\tilde{Q}_{t}(x, \cdot)$ has the density

$$
q_{t}^{0}(x, y)=\frac{1}{2 t}\left(\frac{y}{x}\right)^{-1 / 2} \exp \left\{-\frac{x+y}{2 t}\right\} I_{1}\left(\frac{\sqrt{x y}}{t}\right)
$$

The transition density for $\mathrm{BES}^{\delta}$ is obtained from (49), (50) or (51) and is equal to

$$
p_{t}^{\delta}(x, y)=\frac{1}{t}\left(\frac{y}{x}\right)^{v} y \exp \left\{-\frac{x^{2}+y^{2}}{2 t}\right\} I_{v}\left(\frac{x y}{t}\right)
$$

with $t>0, x>0$, and

$$
p_{t}^{\delta}(0, y)=2^{-v} t^{-(v+1)} \Gamma(v+1)^{-1} y^{2 v+1} \exp \left\{-\frac{y^{2}}{2 t}\right\}
$$

for $\delta>0$, and the semigroup for $\mathrm{BES}^{0}$ is equal to

$$
P_{t}^{0}(x, \cdot)=\exp \left\{-\frac{x^{2}}{2 t}\right\} \varepsilon_{0}+\tilde{P}_{t}(x, \cdot)
$$

where $\varepsilon_{0}$ is the Dirac measure in 0 and $\tilde{P}_{t}(x, \cdot)$ has the density

$$
p_{t}^{0}(x, y)=\frac{x}{t} \exp \left\{-\frac{x^{2}+y^{2}}{2 t}\right\} I_{1}\left(\frac{x y}{t}\right)
$$

## A.3. Scaling property

$\mathrm{BES}^{\delta}$ processes have the Brownian scaling property, that is, if $X$ is a $\mathrm{BES}_{x}^{\delta}$, then the process $c^{-1} X_{c^{2} t}$ is a $\mathrm{BES}_{x / c}^{\delta}$ for any $c>0$. $\mathrm{BESQ}^{\delta}$ processes have the following scaling property: if $X$ is a $\mathrm{BESQ}_{x}^{\delta}$, then the process $c^{-1} X_{c t}$ is a $\mathrm{BES}_{x / c}^{\delta}$.

## A.4. Additivity property of squared Bessel processes

An important and well-known property of $\mathrm{BESQ}^{\delta}$ processes with $\delta \geqslant 0$ is the following additivity property.

Theorem 7 (Shiga and Watanabe 1973). For every $\delta, \delta^{\prime} \geqslant 0$ and $x, x^{\prime} \geqslant 0$,

$$
Q_{x}^{\delta} * Q_{x^{\prime}}^{\delta^{\prime}}=Q_{x+x^{\prime}}^{\delta+\delta^{\prime}}
$$

where $Q_{x}^{\delta} * Q_{x^{\prime}}^{\delta^{\prime}}$ denotes the convolution of $Q_{x}^{\delta}$ and $Q_{x^{\prime}}^{\delta^{\prime}}$.
For a proof, see Shiga and Watanabe (1973) or Revuz and Yor (1999, Chapter XI, Theorem (1.2)).

## Appendix B. Time reversal

Consider a transient diffusion $X$, living on $\mathbb{R}_{+}$, with $X_{0}=x_{0} \geqslant 0$. Denote its last exit time of $a \geqslant 0$ by $L_{a}=\sup \left\{u \mid X_{u}=a\right\}$, where $\sup \varnothing=0$. For $a$ fixed, $L_{a}$ is finite almost surely, and for $x_{0}<a, L_{a}>0$ almost surely. We consider the time-reversed process $\tilde{X}$, where

$$
\tilde{X}_{t}(\omega) \equiv \begin{cases}X_{L_{a}(\omega)-t}(\omega), & \text { if } 0<t<L_{a}(\omega)  \tag{52}\\ \partial & \text { if } L_{a}(\omega) \leqslant t \text { or } L_{a}(\omega)=\infty\end{cases}
$$

where $\partial$ denotes the 'cemetery', and $\tilde{X}_{0}(\omega)=X_{L_{a}(\omega)}(\omega)$, if $0<L_{a}(\omega)<\infty$, else $\tilde{X}_{0}(\omega)=\partial$. As a consequence, we have the equality

$$
\begin{equation*}
\left\{X_{u}, u \leqslant L_{a}\right\}=\left\{\tilde{X}_{T_{0}-u}, u \leqslant T_{0}\right\} \tag{53}
\end{equation*}
$$

where we assume $X$ starting at 0 and $T_{0} \equiv \inf \left\{u \mid \tilde{X}_{u}=0\right\}$.
We remark that a diffusion may be reversed at cooptional times, a more general class than last exit times; see Nagasawa (1964; 1993) or Revuz and Yor (1999, Chapter VII, §4). However, for our purposes here it is reasonable to restrict ourselves to last exit times. In the following, we state a general time-reversal result (see Nagasawa 1964; 1993; Sharpe 1980; Getoor and Sharpe 1979; Revuz and Yor 1999). Denote the semigroup of $X$ by $\left(P_{t}\right)$, the potential kernel of $X$ by $U$, and let $\tilde{\mathcal{F}}_{t}=\sigma\left(\tilde{X}_{s}, s \leqslant t\right)$ be the natural filtration of $\tilde{X}$.

Theorem 8. We assume that there is a probability measure $\mu$ such that the potential $v=\mu U$ is a Radon measure. Further, we assume that there is a second semigroup on $\mathbb{R}^{+}$, denoted by $\left(\hat{P}_{t}\right)$, such that $\hat{P}_{t} f$ is right-continuous in $t$ for every continuous function $f$ with compact support on $\mathbb{R}^{+}$and such that the resolvents $\left(U_{p}\right)$ and $\left(\hat{U}_{p}\right)$ are in duality with respect to $v$, that is,

$$
\begin{equation*}
\int U_{p} f \cdot g \mathrm{~d} v=\int f \cdot \hat{U}_{p} g \mathrm{~d} v \tag{54}
\end{equation*}
$$

for every $p>0$ and all positive Borel functions $f$ and $g$. Equality (54) can also be written as

$$
\left\langle U_{p} f, g\right\rangle_{v}=\left\langle f, \hat{U}_{p} g\right\rangle_{v}
$$

Then under $P_{\mu}$, the process $\tilde{X}$ is a Markov process with respect to $\left(\tilde{\mathcal{F}}_{t}\right)$ with transition semigroup $\left(\hat{P}_{t}\right)$ and we have the duality

$$
\left\langle P_{\phi} f, g\right\rangle_{v}=\left\langle f, \hat{P}_{\phi} g\right\rangle_{v}
$$

for any positive Borel function $\phi$ on $\mathbb{R}^{+}$where $P_{\phi} f(x)=\int_{0}^{\infty} \phi(t) P_{t} f(x) \mathrm{d} t$.
We will obtain explicit formulae for time-reversed diffusions via Doob's $h$-transform.

## B.1. Doob's $\boldsymbol{h}$ transform

Consider a one-dimensional diffusion $X$, with sample space $\left(I^{\partial, \infty}, \mathcal{F}_{\infty}^{0}\right)$, where $I \subseteq[-\infty, \infty]$ and $I^{\partial, \infty}:=\{\omega:[0, \infty) \mapsto I \cup\{\partial\}\}, \mathcal{F}_{\infty}^{0}:=\sigma\{\omega(t) \mid t \geqslant 0\}$.

Definition 5. A non-negative measurable function $h: I \mapsto \mathbb{R} \cup\{\infty\}$ is called $\alpha$-excessive for $X, \alpha \geqslant 0$, if
(i) $\mathrm{e}^{-\alpha t} \mathrm{E}_{x}\left(h\left(X_{t}\right)\right) \leqslant h(x)$, for all $x \in I, t \geqslant 0$,
(ii) $\mathrm{e}^{-\alpha t} \mathrm{E}_{x}\left(h\left(X_{t}\right)\right) \rightarrow h(x)$, for all $x \in I$ as $t \downarrow 0$.

A 0-excessive function is simply called excessive.
Let $h$ be an $\alpha$-excessive function for a diffusion $X$. The lifetime of a path $\omega \in I^{\partial, \infty}$ is defined by $\zeta(\omega):=\inf \left\{t \mid \omega_{t}=\partial\right\}$. We construct a new probability measure $P^{h}$ by

$$
\begin{equation*}
\left.P_{x}^{h}\right|_{\mathcal{F}_{t}}=\left.\mathrm{e}^{-\alpha t} \frac{h(\omega(t))}{h(x)} P_{x}\right|_{\mathcal{F}_{t}} \tag{55}
\end{equation*}
$$

for $t<\xi$ and $x \in I$. The process under the new measure $P^{h}$ is a regular diffusion and is called Doob's $h$-transform of $X$. As for Doob's $h$-transform, we refer to Doob (1984) and Dellacherie et al. (1992); in presenting Doob's $h$-transform we have followed Borodin and Salminen (2002).

As an application let us consider a transient diffusion $X$ under probability measure $P$ with scale function $s$. Doob's $h$-transform of $X$ with the excessive function $h \equiv s$, that is, the process under the new measure $P^{h}$, is a process which reaches 0 almost surely. We have

$$
\begin{equation*}
\left.P_{x}\right|_{\mathcal{F}_{t}}=\left.\frac{(1 / s)\left(X_{t \wedge T_{0}}\right)}{(1 / s)(x)} P_{x}^{h}\right|_{\mathcal{F}_{t}} \tag{56}
\end{equation*}
$$

Note that we obtain

$$
\left.\left.\frac{s\left(X_{t}\right)}{s(x)} P_{x}\right|_{\mathcal{F}_{t}} \equiv 1_{\left(t<T_{0}\right)} P_{x}^{h}\right|_{\mathcal{F}_{t}}
$$

and hence,

$$
\begin{equation*}
Q_{t}^{h} f(x) \equiv \frac{1}{s(x)} \mathrm{E}_{x}\left[(f s)\left(X_{t}\right)\right] \equiv \frac{1}{s(x)} P_{t}(f s)(x) \tag{57}
\end{equation*}
$$

is the semigroup of the process under $P^{h}$ killed when it reaches 0 . In other words, we have the following time-reversal result: Doob's $h$-transform of the transient process under $P$ with $h=s$ is the process under $P^{h}$ killed at $T_{0}$; this is the process $\tilde{X}$ in our former notation.

From formula (56) we can obtain explicit formulae of the diffusion processes via Girsanov's theorem. Assume that a process $\left(X_{t}\right)$ under $P_{x}$ has the form

$$
X_{t}=x+\int_{0}^{t} \beta\left(X_{u}\right) \mathrm{d} u+\int_{0}^{t} \alpha\left(X_{u}\right) \mathrm{d} B_{u}
$$

then via Girsanov's theorem we obtain, using (56), that the process under $P_{x}^{h}$ has the form

$$
\begin{equation*}
X_{t}=x+\int_{0}^{t}\left(\beta+\left(\alpha \frac{s^{\prime}}{s}\right)\right)\left(X_{u}\right) \mathrm{d} u+\int_{0}^{t} \alpha\left(X_{u}\right) \mathrm{d} \hat{B}_{u}, \quad t \leqslant T_{0} \tag{58}
\end{equation*}
$$

## Acknowledgements

The first named author gratefully acknowledges support from RiskLab, Switzerland. We would like to thank an anonymous referee whose suggestions were decisive to treat the case $\lambda<0$ in Section 2.
