Algebraic Signal Processing Theory Markus Püschel Electrical and Computer Engineering Carnegie Mellon University

Collaborators: José Moura (ECE, CMU) Martin Rötteler (NEC, Princeton) Jelena Kovacevic (BME, CMU)

This work was funded by NSF under awards SYS-9988296 and SYS-310941

Preliminaries

- Algebra (as used in this talk) is the theory of groups, rings, and fields
- The scope of the algebraic theory is linear signal processing (SP)
- In this talk we focus on the discrete case (infinite and finite signals)

Background papers:

Basic theory (main paper): Püschel and Moura, "Algebraic Theory of Signal Processing," submitted

• Fast algorithms:

Püschel and Moura, "Algebraic Theory of Signal Processing: 1-D Cooley-Tukey Type Algorithms," submitted Püschel and Moura (SIAM J. Comp 03) and earlier work (Egner and Püschel)

- New lattice transforms: Püschel and Rötteler (ICASSP '04, DSP '04, ICASSP '05, ICIP '05)
- Sampling: Kovacevic and Püschel (ICASSP '06)

Organization

Overview

The algebraic structure underlying linear signal processing

From shift to signal model: Time and space

From infinite to finite signal models

Fast algorithms

Conclusions

The Basic Idea

 SP is built around the key concepts: signals, filters (convolution), z-transform, spectrum, Fourier transform

	infinite time	finite time	infinite space	finite space	other models	generic case
	z-transform	finite _? z-transform	C-transform	finite C-transform	lattice	Φ
set of signals	Laurent series in z ⁻ⁿ	polynomials in z ⁻ⁿ	series in C _n	polynomials in C _n ?	e-variant /quincunx	\mathcal{M}
set of filters	Laurent series in z ⁻ⁿ	polynomials in z ⁻ⁿ	series in T _n	polynomials in T _n	next neighbor time-variant spatial hexagonal/quincunx and others	${\cal A}$
Fourier transform	DTFT	DFT	DSFT?	DCTs/DSTs	next neighbo spatial hexag and others	${\cal F}$
						dervatio

Algebraic theory: All are instantiations of the same theory

The Basic Idea (cont'd)

Key concept in the algebraic theory:

- Infinite and finite time and infinite and finite space are signal models
- But many others are possible
- Once the signal model is defined, all other concepts follow

Why Algebraic Theory?

Identifies the filtering (convolution), "z-transform," spectrum, etc., that goes with the DCTs/DSTs and other existing transforms

Explains boundary conditions for finite signal models

• E.g., why periodic for DFT and symmetric for the DCTs.

New signal models beyond time

- Space
- Space in higher dimension (nonseparable hexagonal lattice, quincunx lattice)

A comprehensive theory of fast transform algorithms

- Current state: Hundreds of publications, but ...
- Algebraic theory: Concise derivation, classification, reason for existence, many new fast algorithms found for DCTs/DSTs and new lattice transforms

What we are <u>Not</u> Trying to do

Restate existing knowledge in a more complicated way

Do math for the math's sake

Provide a theory that is purely "descriptive," i.e., cannot be applied

The algebraic theory is "operational:"

- Enables the derivation of new signal models
- Enables the derivation of new fast algorithms for existing and new transforms

Organization

Overview

■ The algebraic structure underlying linear signal processing

From shift to signal model: Time and space

From infinite to finite signal models

Fast algorithms

Conclusions

The Algebraic Structure of Signal and Filter Space

Signal space, available operations:

- signal + signal = signal
- $\alpha \cdot \text{signal} = \text{signal}$

Filter space, available operations:

- filter + filter = filter
- $\alpha \bullet \text{filter} = \text{filter}$
- filter filter = filter

Filters operate on signals:

filter • signal = signal

(Algebraic) Signal Model

Signals arise as sequences of numbers $(s_n)_{n \in I} \in \mathbb{C} \times \mathbb{C} \times \cdots = \mathbb{C}^I$

 To obtain a notion of filtering, Fourier transform, etc., one needs to assign module and algebra

Example: infinite discrete time: $(s_n)_{n \in \mathbb{Z}}$ z-transform: Φ : $(s_n)_{n \in \mathbb{Z}} \mapsto \sum s_n z^{-n} \in \mathcal{M}$ $\mathcal{M} = \{\sum s_n z^{-n}\}, \quad \mathcal{A} = \{\sum h_k z^{-k}\}$ signal model

Signal model (definition): $(\mathcal{A}, \mathcal{M}, \Phi)$

${\cal A}$	algebra of filters
${\mathcal M}$	an $\mathcal A$ -module of signals
Φ	linear mapping $\mathbb{C}^I o \mathcal{M}$

Algebras Occurring in SP: Shift-Invariance

What is the shift?

- A special filter x (= z^{-1}) = an element of \mathcal{A}
- Filters expressible as polynomials/series in x

shift(s) = generator(s) of A

Shift-invariance $x \cdot h = h \cdot x$ for all $h \in \mathcal{A}$

signal model $(\mathcal{A}, \mathcal{M}, \Phi)$ is shift-invariant $\Leftrightarrow \mathcal{A}$ is commutative

Shift-invariant + finite-dimensional (+ one shift only):

 $\mathcal{A} = \mathbb{C}[x]/p(x)$ polynomial algebra

Example: Finite Time Model and DFT

Finite signals: $(s_0, \ldots, s_{n-1}) \quad \dim(\mathcal{M}), \dim(\mathcal{A}) < \infty$

Signal model: $\mathcal{A} = \mathcal{M} = \mathbb{C}[x]/(x^n - 1)$ $h(x) = \sum_{k=0}^{n-1} h_k x^k \in \mathcal{A}, \quad s(x) = \sum_{i=0}^{n-1} s_i x^i \in \mathcal{M}$ $h(x) \cdot s(x) \mod (x^n - 1)$ Filtering = cyclic convolution $\Phi: (s_0, \dots, s_{n-1}) \mapsto s(x) = \sum s_i x^i \in \mathcal{M}$ Finite z-transform

Spectrum and Fourier transform from Chinese remainder theorem $\mathcal{F}: \mathbb{C}[x]/(x^n-1) \rightarrow \mathbb{C}[x]/(x-\omega_n^0) \oplus \ldots \oplus \mathbb{C}[x]/(x-\omega_n^{n-1})$ $s(x) \mapsto (s(\omega_n^0), \ldots, s(\omega_n^{n-1}))$

Summary so far

Signal model $(\mathcal{A}, \mathcal{M}, \Phi)$

Shift-invariance: A is commutative

• in addition finite makes \mathcal{A} a polynomial algebra

Infinite and finite time are special cases of signal models

How to go beyond time?

Answer: Derivation of signal model from shift

shift signal model
$$(\mathcal{A}, \mathcal{M}, \Phi)$$

Organization

Overview

The algebraic structure underlying linear signal processing

From shift to signal model: Time and space

- From infinite to finite signal models
- Fast algorithms

Conclusions

. . .

 t_{n+k}

Chebyshev polynomials

Operation of filters on signals is automatically defined (the linear extension of the shift operation)

Time and Space (cont'd)

Chebyshev polynomials

Time: we are done $\mathcal{M} = \{\sum s_n x^n\}$

ace:

$$\mathcal{A} = \{\sum h_k T_k\}$$

 $\mathcal{M} = \{\sum s_n C_n\}$
but:
 \mathcal{O}

each a linear combination C_{-1} C_0 C_1 C_2 linearly independent of C_n , $n \ge 0$

Signal model only for right-sided sequences:

$$\Phi: (s_n)_{n\geq 0} \mapsto \sum_{n\geq 0} s_n C_n$$
 C-transform

Left Signal Extension

Chebyshev polynomials

Simplest signal extension: monomial $C_{-n} = aC_k$

Monomial if and only if $C \in \{T, U, V, W\}$

Visualization

Infinite discrete time (z-transform)

Infinite discrete space (C-transform, C=T,U,V,W)

left boundary

From shift to signal model: Time and space

From infinite to finite signal models

Fast algorithms

Conclusions

Derivation: Finite Time Model

no module

Solution: Right boundary condition

$$egin{aligned} &x^n = a_{n-1}x^{n-1} + \cdots + a_0x^0\ &\Rightarrow &p(x) = x^n - a_{n-1}x^{n-1} - \cdots - a_0x^0 = 0\ &&\mathcal{M} = \mathcal{A} = \mathbb{C}[x]/p(x) \end{aligned}$$

Monomial signal extension: $p(x) = x^n - a, \quad a \neq 0$ (a = 1: finite z-transform)

periodic

Derivation: <u>Finite</u> Space Model

not closed under shiftno module

Monomial signal extension: For each $C \in \{T, U, V, W\}$ four cases

$$C_n = C_{n-2}$$

 $C_n = 0$
 $C_n = C_{n-1}$
 $C_n = -C_{n-1}$

■ 16 finite space models ⇔ 16 DCTs/DSTs as Fourier transforms

16 Finite Space Models

Example: Signal model for DCT, type 2:

$$\begin{aligned} \mathcal{A} &= \mathbb{C}[x]/2(x-1)U_{n-1} = \{\sum_{k=0}^{n-1} h_k T_k\} \\ \mathcal{M} &= \mathbb{C}[x]/2(x-1)U_{n-1} = \{\sum_{i=0}^{n-1} s_i V_i\} \end{aligned} \quad \Phi: \ (s_i)_{0 \le i < n} \mapsto \sum_{i=0}^{n-1} s_i V_i \end{aligned}$$

1D Trigonometric Transforms

 Signal models for all existing (and some newly introduced) trigonometric transforms (~30)

 Explains all existing trigonometric transforms

 Gives for each transform associated "z-transform" filters, etc.

source: "Algebraic Theory of Signal Processing," submitted 23

More Exotic 1-D Model

Generic next neighbor shift

Space variant but shift invariant

- Same procedure yields infinite and finite models
- Connects to orthogonal polynomials

Applications?

Top-Down: 1-D Time (Directed) Models

$$h\star s=\int s(au)h(t- au)d au$$

$$h \star s = \int s(\tau) \frac{1}{2} (h(t+\tau) + h(t-\tau)) d\tau$$

DCT, type III

II. THE ODD-FACTOR ALGORITHM The length-N IDCT of input sequence X(k) is defined by

$$x(n) = \sum_{k=0}^{N-1} X(k) \cos \frac{\pi (2n+1)k}{2N} \qquad 0 \le n \le N-1 \quad (1)$$

where sequence length N is an arbitrarily composite integer expressed by

$$N = 2^{m} \times q = 2^{m} \times \prod_{i=1}^{\infty} (2i+1)^{r_{i}}$$
(2)

Algorithm derivation

mutually prime). The IDCT can be decomposed into

$$\begin{aligned} x \left(qn + \frac{q-1}{2}\right) \\ &= \sum_{k=0}^{N-1} X(k) \cos \frac{\pi (2n+1)k}{2(N/q)} \\ &= \sum_{k=0}^{N-1} X(k) \cos \frac{\pi [q(2n+1) - (q-1-2m)]k}{2N} \\ &= \sum_{k=0}^{N-1} X(k) \cdot \cos \frac{\pi [q(2n+1) + (q-1-2m)]k}{2N} \end{aligned}$$
(4)

where for (3)–(5), n = 0 to N/q - 1 and m = 0 to (q - 3)/2. Equation (3) can be rewritten into

$$\begin{aligned} x \bigg(qn + \frac{q-1}{2}\bigg) \\ &= \sum_{k=1}^{N/q-1} \left\{ \sum_{i=1}^{(q-1)/2} X\bigg(\frac{2iN}{q} + k\bigg) \\ &\cdot \cos \frac{\pi (2n+1)(2iN/q+k)}{2(N/q)} \\ &+ \sum_{k=1}^{(q-1)/2} X\bigg(\frac{2iN}{q} - k\bigg) \\ &\cdot \cos \frac{\pi (2n+1)(2iN/q-k)}{2(N/q)} \right\} \end{aligned}$$

$$+\sum_{k=1}^{N/q-1} X(k) \cos \frac{\pi (2n+1)k}{2(N/q)} \\ +\sum_{i=0}^{(q-1)/2} X\left(\frac{2iN}{q}\right) \cos \frac{\pi (2n+1)(2iN/q)}{2(N/q)} \\ =\sum_{k=1}^{N/q-1} \left\{ X(k) + \sum_{i=1}^{(q-1)/2} (-1)^i \left[X\left(\frac{2iN}{q} + k\right) + X\left(\frac{2iN}{q} - k\right) \right] \right\} \cos \frac{\pi (2n+1)k}{2(N/q)} \\ + \left\{ \sum_{i=0}^{(q-1)/2} (-1)^k X\left(\frac{2iN}{q}\right) \right\} \\ =\sum_{i=0}^{N/q-1} U(k) \cos \frac{\pi (2n+1)k}{2(N/q)}.$$
(6)

It is noted that input x[(2i+1)N/q] is excluded from (6). By defining $S_i(k) = X(2iN/q+k) + X(2iN/q-k)$ and $T_i(k) = X(2iN/q+k) - X(2iN/q-k)$, where $i = 1, \cdots, (q-1)/2$, we have

$$(k) = \begin{cases} X(k) + \sum_{i=1}^{(q-1)/2} (-1)^i S_i(k) & k = 1, \cdots, N/q - 1\\ \sum_{i=0}^{(q-1)/2} (-1)^i X\left(\frac{2iN}{q}\right) & k = 0. \end{cases}$$
(7)

Therefore, (6) can be computed by a length-N/q IDCT. By combining (4) and (5), we form two new sequences defined by

U

$$F(n,m) = \frac{x(qn+m) + x(qn+q-m-1)}{2}$$
$$= \sum_{k=0}^{N-1} X(k) \cos \frac{\pi(q-1-2m)k}{2N}$$
$$\cdot \cos \frac{\pi(2n+1)k}{2(N/q)}$$
$$G(n,m) = \frac{x(qn+m) - x(qn+q-m-1)}{2}$$
$$= \sum_{k=0}^{N-1} X(k) \sin \frac{\pi(q-1-2m)k}{2N}$$
$$\cdot \sin \frac{\pi(2n+1)k}{2(N/q)}.$$

(8)

(9)

If we define
$$\alpha=\pi(q-1-2m)$$
 for simplicity, (8) can be furthed ecomposed into

$$\begin{split} F(n,m) &= \sum_{k=1}^{N/q-1} \left\{ \sum_{i=1}^{(q-1)/2} X\left(\frac{2iN}{q} + k\right) \right. \\ &\left. \cdot \cos\frac{\alpha(2iN/q + k)}{2N} \cos\frac{\pi(2n+1)(2iN/q + k)}{2(N/q)} \right. \\ &\left. + \sum_{i=1}^{(q-1)/2} X\left(\frac{2iN}{q} - k\right) \right. \\ &\left. \cdot \cos\frac{\alpha(2iN/q - k)}{2N} \cos\frac{\pi(2n+1)(2iN/q - k)}{2(N/q)} \right. \\ &\left. + \sum_{i=1}^{N/q-1} X(k) \cos\frac{\alpha k}{2N} \cos\frac{\pi(2n+1)k}{2(N/q)} \right] \end{split}$$

$$+\sum_{i=0}^{(q-1)/2} X\left(\frac{2iN}{q}\right) \cos\frac{i\alpha}{q} \\ \cdot \cos\frac{\pi(2n+1)(2iN/q)}{2(N/q)} \\ =\sum_{k=1}^{N/q-1} \sum_{i=1}^{(q-1)/2} (-1)^i \left\{S_i(k) \cos\frac{\pi\alpha_i}{q} \cos\frac{\alpha k}{2N} - T_i(k) \sin\frac{\alpha i}{q} \sin\frac{\alpha k}{2N}\right\} \cos\frac{\pi(2n+1)k}{2(N/q)} \\ +\sum_{k=1}^{N/q-1} X(k) \cos\frac{\alpha k}{2N} \cos\frac{\pi(2n+1)k}{2(N/q)} \\ +\sum_{i=0}^{(q-1)/2} (-1)^i X\left(\frac{2iN}{q}\right) \cos\frac{\alpha i}{q} \\ =\sum_{k=0}^{N/q-1} V(k,m) \cos\frac{\pi(2n+1)k}{2(N/q)}$$
(1)

sequence length that is a power of odd integers. Therefore, the odd-factor algorithm is general and particularly suited to sequence length containing any possible combination of odd factors. Fig. 1 shows an example for N = 27. In principle, the proposed odd-factor algorithm is the reverse process of the FDCT algorithm presented in [12].

For a composite sequence length containing both odd and even factors, the radix-2 and the odd-factor algorithms can be jointly used. In principle, the decomposition process can be carried out in many ways. However, a lower count of operations is obtained if the decomposition process starts with the ascending order of the factors of N. To minimize the required number of arithmetic operations, we generally prefer a computational complexity whose growth rate with the sequence length is as small as possible. In [12], it was proved that the growth rate of the computational complexity is proportional to the values of the odd factors. From Fig. 2, which shows the computational complexity in terms of the number of arithmetic operations per transform point, it can be observed that the growth rate of the computational complexity with the sequence lengths for $N = 5^m$ is larger than that for $N = 3^m$, and the smallest growth rate is achieved for $N = 2^m$. This observation indicates that the smallest

Fast Algorithms: Cooley-Tukey FFT

Signal model: Finite z-transform $\mathcal{A} = \mathcal{M} = \mathbb{C}[x]/(x^n - 1)$

$$\Phi: \; (s_0,\ldots,s_{n-1})\mapsto s(x)=\sum s_i x^i\in \mathcal{M}$$

Fourier transform

$$\mathrm{DFT}_n: \ \mathbb{C}[x]/(x^n-1) \ o \ \mathbb{C}[x]/(x-\omega_n^0)\oplus\ldots\oplus\mathbb{C}[x]/(x-\omega_n^{n-1})$$

$y = \mathrm{DFT}_n \cdot s$ $\mathrm{DFT}_n = [\omega_n^{k\ell}]_{0 \leq k, \ell \leq n}$ $y_k = \sum_{\ell=0}^{n-1} \omega_n^{k\ell} s_\ell$

Cooley-Tukey FFT

 $y_{n_2 j_1 + j_2} = \sum_{k_1 = 0}^{n_1 - 1} \left(\omega_n^{j_2 k_1} \right) \left(\sum_{k_2 = 0}^{n_2 - 1} x_{n_1 k_2 + k_1} \omega_{n_2}^{j_2 k_2} \right) \omega_{n_1}^{j_1 k_1} \qquad \text{DFT}_n = L_{n_2}^n (I_{n_1} \otimes \text{DFT}_{n_2}) T_{n_1}^n (\text{DFT}_{n_1} \otimes I_{n_2})$

Cooley-Tukey FFT Type Algorithms

Example:

 $x^n - 1 = (x^m)^k - 1$ yields Cooley-Tukey FFT DFT $_n = L^n_m (I_k \otimes \mathrm{DFT}_m) T^n_m (\mathrm{DFT}_k \otimes I_m)$
