#### Abstract

**Background:** Evidence regarding the effectiveness of allergen immunotherapy (AIT) on allergic rhinitis has been provided mostly by randomised controlled trials, with little data from real-life studies.

**Objective:** To compare the reported control of allergic rhinitis symptoms in three groups of users of the MASK-air<sup>®</sup> app: those receiving sublingual AIT (SLIT), those receiving subcutaneous AIT (SCIT), and those receiving no AIT.

**Methods:** We assessed the MASK-air<sup>®</sup> data of European users with self-reported grass pollen allergy, comparing the data reported by patients receiving SLIT, SCIT and no AIT. Outcome variables included the daily impact of allergy symptoms globally and on work (measured by visual analogue scales—VASs), and a combined symptom-medication score (CSMS). We applied Bayesian mixed-effects models, with clustering by patient, country and pollen season.

**Results:** We analysed a total of 42,756 days from 1,093 grass allergy patients, including 18,479 days of users under AIT. Compared to no AIT, SCIT was associated with similar VAS levels and CSMS. Compared to no AIT, SLIT-tablet was associated with lower values of VAS global allergy symptoms (average difference = 7.5 units out of 100; 95% credible interval [95%CrI] = −12.1;−2.8), lower VAS Work (average

difference = 5.0; 95%CrI = -8.5;-1.5), and a lower CSMS (average difference = 3.7; 95%CrI = -9.3;2.2). When compared to SCIT, SLIT-tablet was associated with lower VAS global allergy symptoms (average difference = 10.2; 95%CrI = -17.2;-2.8), lower VAS Work (average difference = 7.8; 95%CrI = -15.1;0.2), and a lower CSMS (average difference = 9.3; 95%CrI = -18.5;0.2).

**Conclusion:** In patients with grass pollen allergy, SLIT-tablet, when compared to no AIT and to SCIT, is associated with lower reported symptom severity. Future longitudinal studies following internationally-harmonised standards for performing and reporting real-world data in AIT are needed to better understand its 'real-world' effectiveness.

#### KEYWORDS

allergic rhinitis, immunotherapy, mobile health, patient-reported outcomes, real-life data analysis

## 1 | INTRODUCTION

Allergen immunotherapy (AIT) is an effective treatment for allergic rhinitis and/or asthma, as demonstrated by large well-designed randomised controlled trials (RCTs).<sup>1-3</sup> Such RCTs have been carried out with large studies on sublingual immunotherapy (SLIT)<sup>1,2</sup> and with smaller ones on subcutaneous immunotherapy (SCIT).<sup>3,4</sup> Based on the available evidence for both application routes,<sup>5</sup> several guidelines with clinical evidence-based recommendations have recently been published by the European Academy of Allergy and Clinical Immunology<sup>6</sup> and Allergic Rhinitis and its Impact on Asthma (ARIA; an expert consortium issuing recommendations based on a GRADE evaluation).<sup>7-10</sup>

While RCTs are requested for market authorisation purposes, following the formal regulation by authorities such as the European Medicines Agency, they narrow the study population based on specific criteria as pre-defined in study protocols.<sup>11</sup> It is unclear as to whether the effects of treatments seen in highly-controlled RCTs are similar to those in less-controlled pragmatic study designs, such as large observational studies (often referred to as 'real-world data' [RWD]).<sup>11</sup>

Results from clinical trials should therefore be complemented with those from RWD, which can be obtained using data from electronic health records or from monitoring tools such as mobile apps. Several retrospective studies in administrative databases have suggested the efficacy of AIT in rhinitis and asthma.<sup>12,13</sup> Evidence from mobile apps is more scarce, but RWD obtained from mobile apps is an increasing and demanding field, not only in the allergy domain, but also in several other chronic diseases, including different conditions such as sleep disturbances,<sup>14</sup> rheumatologic diseases<sup>15</sup> or diabetes.<sup>16</sup> This reflects the high potential of mobile apps for scientific purposes, patient self-management and/or adherence, as well as the encouraging results some apps have displayed in improving adherence and/or clinical trials.<sup>17</sup> A recent proof-of-concept study clearly

demonstrated that MASK-air<sup>®</sup> (a mobile app with a monitoring questionnaire assessing the impact of allergic symptoms, work and medication use each day<sup>18,19</sup>) is a valuable tool for assessing the impact of AIT.<sup>20</sup> This first analysis revealed that days under AIT are associated with approximately a 25% improved control of allergic rhinitis symptoms. Interestingly, the same magnitude of effect was observed when comparing days without symptomatic treatment versus those under monotherapy and those under co-medication.<sup>20</sup> However, this study did not compare the different application routes of AIT and the treatment schedules, neither did it take into account the different countries or pollen seasons.

Therefore, the aim of the present study was to use MASK-air<sup>®</sup> RWD to compare the reported control of allergic rhinitis symptoms in SCIT, SLIT and no AIT users allergic to grass pollen.

## 2 | METHODS

### 2.1 | Study design

This is a cross-sectional study using MASK-air<sup>®</sup> data. We compared SCIT, SLIT-tablet and no AIT for the severity of reported allergic rhinitis symptoms, their impact on work and a combined symptom-medication score (CSMS). We took into account the differences across users, countries and seasons, by performing analyses in which the observations were clustered by user, country and season.

### 2.2 | Setting

MASK-air<sup>®</sup> was initiated in 2015 and is available in 27 countries ([www.mask-air.com](http://www.mask-air.com)).<sup>21,22</sup> For each AIT-specific item, we included data from all MASK-air<sup>®</sup> European countries with at least 150 days of reporting.

## 2.3 | Participants

We included users aged 16–90 years, who reported allergic rhinitis and allergy to grass pollen.<sup>21</sup> In the app, they reported whether or not they were under AIT (SCIT/SLIT). All analysed data concerned the period 21 May 2015 to 6 December 2020.

## 2.4 | Ethics

MASK-air<sup>®</sup> is CE1 registered and follows the General Data Protection Regulation.<sup>23</sup> An independent review board approval was not required for this specific study as it is an observational study. All data were anonymised prior to the study (including geolocation-related data) using *k*-anonymity, and users agreed to the analysis of their data in the terms of use (translated into all languages and customised according to the legislation of each country, allowing the use of the results for research purposes).

## 2.5 | Data sources and variables

MASK-air<sup>®</sup> comprises a daily monitoring questionnaire which assesses the impact of allergic rhinitis using visual analogue scales (VASs) on a 0–100 scale, which display high intra-rater validity and moderate-high validity, test-retest reliability and responsiveness (Supplementary Table S2).<sup>24</sup> The questionnaire includes a question on how much overall allergic rhinitis symptoms are bothering the user on that day ('VAS Global Allergy Symptoms'), as well as one on how much allergic symptoms are affecting work on that day ('VAS Work'; only presented if the user reports to be working on that day). In addition to the VASs, the MASK-air<sup>®</sup> daily monitoring questionnaire asks users whether they took medication or had been under AIT on that day. In the configuration of their -profile, MASK-air<sup>®</sup> users can provide information on their age, sex, country, allergen sensitisation, allergy symptoms, smoking status, and—if under AIT—type of AIT (SCIT or SLIT, including SLIT-tablet).

When responding to the MASK-air<sup>®</sup> daily monitoring questionnaire, it is not possible to skip any of the questions, and data are saved to the dataset only after the final answer. This precludes any missing data.

## 2.6 | Size of the study

For each specific AIT type, we analysed all of the data available from European countries with at least 150 days of use/observations.

## 2.7 | Biases

There are potential information biases related to the self-reported nature of the data collection. Potential selection bias might be

introduced due to the fact that app users are not representative of all patients with rhinitis.

## 2.8 | Data analysis

Categorical variables were described using absolute and relative frequencies, while continuous variables were described using medians and interquartile ranges. In MASK-air<sup>®</sup>, each reporting day corresponds to an observation. We compared the days of patients under SCIT, SLIT-tablet and no AIT. The days of these different groups of patients were compared using VAS Global Allergy Symptoms, VAS Work, and a CSMS<sup>37</sup> (mixed hypothesis- and data-driven score calculated by multiplying VAS Global Allergy Symptoms by a medication factor; Supplementary Table S1).

To perform such comparisons, we applied three hierarchical models (also called 'multilevel models' or 'mixed-effects models')—one for each score. For each model, the type of grass AIT was a fixed effect, while random effects included identification of the user (nested within the respective country) and indication as to whether the observation occurred within or outside the grass pollen season (we used Bedard's method to assess the grass pollen season<sup>25</sup>). In other words, we modelled the association between VAS and AIT type, taking into account the clustering of observations by users, by countries and by seasons (i.e., we adjusted our comparisons according to the clustering of multiple users' observations, of the user's country, and of whether the observation occurred within or outside the pollen season). Additional hierarchical models were built, which also adjusted for the patients' sex, age and comorbidities (asthma and conjunctivitis). Sensitivity analyses were performed with results stratified (i) by days during or outside the pollen season, and (ii) by countries with a higher number of observations under SCIT than under SLIT-tablet versus countries with a higher number of observations under SLIT-tablet than under SCIT.

Hierarchical models were applied using Bayesian methods. We opted for Bayesian approaches as they yield probability distributions of the parameters of interest (posterior probabilities) based on prior probability distributions and on the observed data.<sup>26</sup> That is, in this study, for each comparison, we obtained the posterior probability distribution for the average difference of VAS, retrieving the mean value and the respective 95% credible interval (CrI; range of values within which, with 95% probability, the true VAS difference lies. In Bayesian statistics, uncertainty is expressed through CrI and not through classical confidence intervals or *p*-values). This is a methodological advantage as it informs us of the probability of each AIT type being associated with a lower VAS or CSMS, besides allowing for the obtention of a probability distribution that can be graphically plotted. Uninformative prior distributions of  $\text{dnorm}[0,0.0001]$  and  $\text{dunif}[0,100]$  were respectively used for the regression coefficients and for the precision parameters.

All statistical analyses were performed using the software R (version 4.0.0.) with the *rjags* package. For each analysis, we ran 70,000 iterations with a burn-in of 30,000 sample iterations.

### 3 | RESULTS

#### 3.1 | Characteristics of the patients

We analysed 42,756 days from 1,093 grass allergy patients in 10 countries (Austria, France, Germany, Greece, Italy, Lithuania, Poland, Portugal, Spain and Switzerland). Of those 42,756 days, 18,479 (43.2%) were from users under AIT, including 12,675 days under SCIT (68.6% of AIT days) and 5,804 under SLIT-tablet (31.4% of AIT days). SLIT-drop was not analysed due to the low number of observations. The demographic and clinical characteristics of the patients are given in Table 1. The mean number of days reported per user is 38 for both no AIT and SCIT, and 47 for SLIT-tablet.

#### 3.2 | Major results

Overall, patients receiving AIT had a lower median VAS Global allergy symptoms than patients under no AIT (6 vs. 10, Table 2A), a

lower median VAS Work (2 vs. 7, Table 2C), and a lower median CSMS (8 vs. 11, Table 2C).

By comparison with no AIT, SCIT was associated with similar VAS Global allergy symptom levels (average difference = 0.2 units out of 100, 95%CrI = -3.2;2.8), VAS Work levels (0.6, -2.2;3.4), and CSMS values (0.8, -2.9;4.4). Overall, the probability of SCIT being better than no AIT was 55% for VAS Global allergy symptoms, 34% for VAS Work, and 33% for CSMS (Table 3; Figure 1).

By comparison with no AIT, SLIT-tablet was associated with lower VAS Global allergy symptoms (-7.5, -12.1;-2.8), lower VAS Work (-5.0, -8.5;-1.5), and a lower CSMS (-3.7, -9.3;2.2). The probability of SLIT-tablet being better than no AIT was 99% for both VAS Global allergy symptoms and VAS Work, and 89% for the CSMS.

By comparison with SCIT, SLIT-tablet was also associated with lower VAS Global allergy symptoms (-10.2, -17.2;-2.8), lower VAS Work (-7.8, -15.1;0.2), and a lower CSMS (-9.3, -18.5;0.2). We observed a probability higher than 95% of SLIT-tablet being associated with lower VASs and CSMS when compared to SCIT.

TABLE 3 Results of the comparisons between different grass immunotherapy (allergen immunotherapy [AIT]) types

	Difference in VAS global allergy symptoms	Difference in VAS work	Difference in CSMS
<b>A. Hierarchical models adjusting for the season, country and patient</b>			
SCIT versus no AIT—Mean (CrI) [probability of SCIT being better than no AIT]	-0.2 (-3.2;2.8) [55%]	0.6 (-2.2;3.4) [34%]	0.8 (-2.9;4.4) [33%]
SLIT-tablet versus no AIT—Mean (CrI) [probability of SLIT-tablet being better than no AIT]	-7.5 (-12.1;-2.8) [99%]	-5.0 (-8.5;-1.5) [99%]	-3.7 (-9.3;2.2) [89%]
SLIT-tablet versus SCIT—Mean (CrI) [probability of SLIT-tablet being better than SCIT]	-10.2 (-17.5;-2.8) [99%]	-7.8 (-15.1;0.2) [97%]	-9.3 (-18.5;0.2) [97%]
<b>B. Hierarchical models adjusting for the season, country, patient and his/her characteristics (sex, age and comorbidities)</b>			
SCIT versus no AIT—Mean (CrI) [probability of SCIT being better than no AIT]	0.2 (-2.7;3.6) [47%]	1.1 (-1.6;3.8) [20%]	1.3 (-2.5;4.9) [25%]
SLIT-tablet versus no AIT—Mean (CrI) [probability of SLIT-tablet being better than no AIT]	-7.9 (-12.6;-3.5) [99%]	-4.8 (-8.4;1.1) [99%]	-2.1 (-8.0;3.5) [75%]
SLIT-tablet versus SCIT—Mean (CrI) [probability of SLIT-tablet being better than SCIT]	-9.3 (-15.8;-2.3) [99%]	-8.0 (-16.3;-0.2) [97%]	-8.9 (-17.7;-1.2) [99%]

Abbreviations: CSMS, combined symptom-medication score; SCIT, subcutaneous immunotherapy; SLIT-tablet, sublingual AIT exclusively by tablets; VAS global allergy symptoms, visual analogue scale assessing the overall impact of allergic rhinitis symptoms on the user on that day; VAS Work, visual analogue scale assessing the work impact of allergic rhinitis symptoms on the user on that day.

Similar results were observed in multivariable models adjusting for patients' sex, age and allergic comorbidities (Table 3). Tables 4 and 5 display the results for sensitivity analyses, with results stratified by country group and pollen season. Similar results were observed in separate analyses for countries where more observations were registered for SCIT when compared to those where more observations were registered for SLIT-tablet. On the other hand, we observed larger differences for AIT versus no AIT when comparing days outside pollen seasons to those during pollen seasons.

## 4 | DISCUSSION

There is a clear unmet need for the further development and evaluation of validated tools to investigate the clinical efficacy of AIT under a real-life scenario complementary to RCTs.<sup>27,28</sup> This study

complements a recent proof-of-concept study.<sup>20</sup> It is unique and demonstrates that, in grass pollen allergy patients, SLIT-tablet is associated with lower VAS Global allergy symptoms, lower VAS Work and lower CSMS when compared to SCIT or no AIT. Subcutaneous allergen immunotherapy and no AIT showed similar levels for all three outcomes.

### 4.1 | Strengths and limitations

This study has important strengths. Real-world data from a large set of users from 10 different European countries have been assessed in this analysis. In addition, observations were clustered by users, country and season, thus taking into account certain potential individual confounders. Finally, MASK-air<sup>®</sup> VAS Global allergy symptoms and VAS Work have revealed high intra-rater

**FIGURE 1** Probability distributions of the comparisons between grass subcutaneous immunotherapy (SCIT) versus no allergen immunotherapy (AIT), and grass sublingual immunotherapy (SLIT) by tablet versus no AIT

validity and moderate-high validity, test-retest reliability and responsiveness.<sup>24</sup>

This study also has some further limitations. First, there is the possibility of misclassification, given that the identification of patients with grass allergy and under each AIT type was based on information provided by the patients themselves and not on standardised diagnostics and physician evaluation as recommended in guidelines.<sup>29,30</sup> Such misclassification may lead to an underreporting of both grass allergy and AIT use. To partly account for this, as well as for a longer-lasting effect of AIT, we included all days of the patients reporting to be under AIT, irrespective of the specific days on which AIT was actually used.

Second, selection biases are known to exist in mHealth. MASK-air<sup>®</sup> users are not representative of the general population of allergic rhinitis patients with grass allergy, with an overrepresentation of users suffering from more severe disease and/or receiving more specialised treatment (which would explain why VAS values tend to be higher on the first day of reporting than on subsequent days).<sup>21,22</sup> In addition, it is possible to hypothesise that days with patients feeling worse tend to be more frequently reported than those with patients experiencing no or mild symptoms, although this probably occurs in a non-differential way, irrespective of the AIT type under which the patients may be. However, a differential reporting bias may result from the fact that SLIT-tablet is taken every day, self-administered by the patient, in contrast to SCIT, which is given every 4–6 weeks. On the other hand, as the MASK-air<sup>®</sup> app is to be filled in every day, with each question concerning that specific day, recall bias may not have a substantial impact on our results.

Third, we did not follow a product-specific approach for each AIT application route (as recommended in current international guidelines on AIT<sup>29,30</sup>), but analysed differences between routes of administration in a generic way. Moreover, we did not report on SLIT-drops because there was only one country with more than 150 reported days of SLIT-drops and SLIT-tablet use (France), and only

one country with more than 150 reported days of both SLIT-drops and SCIT (Lithuania). In this country, the mean number of recorded days per user was substantially higher than that observed in other countries.

Fourth, we used, as previously, a cross-sectional design.<sup>20–22</sup> When we launched MASK-air<sup>®</sup>, it was expected that patients would use the app regularly and that it would be possible to perform a longitudinal analysis. However, patients use the app for short periods of time (in this study, a mean number of 39 days were reported per user) and intermittently. Analyses for intermittent use (consecutive and non-consecutive data) have been performed.<sup>21</sup> This cross-sectional approach has been shown to be effective in raising new hypotheses, subsequently confirmed by epidemiologic studies.<sup>31–33</sup> However, the cross-sectional approach of this study precludes the establishment of a causal relationship between AIT use and reported symptoms, as well as the assessment of AIT adherence and therapy duration. Measurement of the latter variables would be particularly relevant given (i) the possible differences in the time needed for SLIT and SCIT to become effective, and (ii) the fact that SCIT may ensue more physician-patient interaction (as, contrary to SLIT, it cannot be self-administered by the patient at home). If patients tend to report symptoms more often when feeling worse or after establishing care with an allergist, this could imply a bias in the estimation of SLIT and SCIT efficacy (particularly in the first months after AIT initiation). Solutions in addressing these methodological biases of real-world evidence in AIT need to be elaborated in the future.

## 4.2 | Findings

While symptom levels are low, suggesting that AIT patients are not severe, a previous study has found median VAS levels of around 50/100 on the first day of reporting (when considering the pollen

**TABLE 4** Results of sensitivity analyses for the comparisons between different grass immunotherapy (allergen immunotherapy [AIT]) types obtained with hierarchical models adjusting for the season, country and patient

Abbreviations: CSMS, combined symptom-medication score; SCIT, subcutaneous immunotherapy; SLIT-tablet, sublingual AIT exclusively by tablets; VAS global allergy symptoms, visual analogue scale assessing the overall impact of allergic rhinitis symptoms on the user on that day; VAS work, visual analogue scale assessing the work impact of allergic rhinitis symptoms on the user on that day.

season).<sup>21</sup> The low VAS levels reported in most observations may at least partly reflect the efficacy of medications. Moreover, we reported days under allergen exposure and days without. A new study has been scheduled to include pollen counts rather than simply accounting for the pollen season.

Taking into account the selection of patients and the nature of observational mHealth studies, this study suggests that grass pollen allergic patients under SLIT-tablet report less severe symptoms than those under no AIT. Several hypotheses can be postulated to explain this finding, including (i) real differences in the efficacy or effectiveness of AIT, (ii) differences in the mode of administration for each AIT type (with SLIT-tablet, contrary to SCIT, being administered at home and on a daily basis), (iii) differences in the time needed for the

various types of AIT to achieve effectiveness, (iv) differences on the baseline symptoms of patients, and (v) the greater diversity of SCIT products compared to SLIT formulations (which may also explain the heterogeneity observed in the meta-analyses of SCIT trials).<sup>34,35</sup> Therefore, conclusions cannot be made on the efficacy or effectiveness of AIT, as several limitations exist (as outlined above). For instance, users under AIT tend to be more closely followed by their physicians and demonstrate a higher adherence to physicians' recommendations (the so-called 'Hawthorne effect' as one component of unspecific treatment effects in AIT<sup>34</sup>). This study prompts the need for future observational prospective studies, combining patients' and physicians' inputs and adjusting for the most relevant confounders.

**TABLE 5** Results of sensitivity analyses for the comparisons between different grass immunotherapy (allergen immunotherapy [AIT]) types obtained with hierarchical models adjusting for the season, country, patient and his/her characteristics (sex, age and comorbidities)

	Difference in VAS global allergy symptoms	Difference in VAS work	Difference in CSMS

Abbreviations: CSMS, combined symptom-medication score; SCIT, subcutaneous immunotherapy; SLIT-tablet, sublingual AIT exclusively by tablets; VAS global allergy symptoms, visual analogue scale assessing the overall impact of allergic rhinitis symptoms on the user on that day; VAS work, visual analogue scale assessing the work impact of allergic rhinitis symptoms on the user on that day.

The effect of AIT on work was previously suggested by two studies using the MASK-air<sup>®</sup> approach.<sup>19,36</sup> In this study, we have confirmed that SLIT-tablet can be associated with improved VAS Work. Once further longitudinal studies have been conducted, this will open the door to ascribing a monetary value to this form of treatment and to performing subsequent economic evaluation studies.

We have used a recently validated CSMS.<sup>37</sup> Differences between SLIT-tablet, SCIT or no AIT were smaller when estimated in relation to the CSMS than in relation to VAS Global allergy symptoms or VAS Work. It is possible that patients under SLIT-tablet have a reduced treatment use which might explain the difference.

### 4.3 | Generalisability

The study was carried out in nine European countries and can be extended to the whole of Europe. However, it does not necessarily apply to countries where AIT is used with different allergen extracts and regimens.

## 5 | CONCLUSION

When compared to no AIT and to SCIT, SLIT was found to be associated with a better allergic rhinitis symptom control, impact on work and CSMS in patients with grass pollen allergy. By contrast, no such

differences were observed when comparing SCIT to no AIT. Following these results, future longitudinal studies are needed (taking potentially relevant confounders into account and following internationally harmonised standards for performing and reporting real-world data in AIT) to assess the effectiveness in improving allergic rhinitis control.

## ACKNOWLEDGEMENT

MASK-air has been supported by Charité Universitätsmedizin Berlin, EU Grants (EU Structural and Development Funds, POLLAR: EIT Health POLLAR, EIT Health Twinning) and educational grants from Mylan-Viatriis, ALK, GSK, Novartis and Uriach.

Open access funding enabled and organized by Projekt DEAL.

RL reports grants and personal fees from GSK, AZ, Chiesi, Novartis, personal fees from Sanofi. MM reports personal fees from Menarini, personal fees from Astra Zeneca, personal fees from GSK, personal fees from Mylan, personal fees from Sanofi, personal fees from Pfizer, personal fees from Chiesi, RM reports personal fees from ALK, allergopharma, Allergy Therapeutics, Friulchem, Hexal, Servier, Klosterfrau, Bayer, FAES, GSK, MSD, Johnson&Johnson, Meda, Stada, UCB, Nuvo, Menarini, Mundipharma, Pohl-Boskamp, grants from ASIT biotech, Leti, Optima, BitopAG, Hulka, Ursapharm, Immunotek, grants and personal fees from Bencard, Stallergenes, grants, personal fees and non-financial support from Lofarma, non-financial support from Roxall, Atmos, Bionorica, Otonomy, Ferrero, personal fees and non-financial support from Novartis. JM reports personal fees and other from SANOFI-GENZYME & REGENERON, NOVARTIS, ALLAKOS, grants and personal fees from MYLAN Pharma, URIACH Group, personal fees from Mitsubishi-Tanabe, Menarini, UCB, AstraZeneca, GSK, MSD. NGP reports personal fees from Novartis, Nutricia, HAL, MENARINI/FAES FARMA, SANOFI, MYLAN/MEDA, BIOMAY, AstraZeneca, GSK, MSD, ASIT BIOTECH, Boehringer Ingelheim, grants from Gerolymatos International SA, Capricare. OP reports grants and personal fees from ALK-Abelló, Allergopharma, g Stallergenes Greer, HAL Allergy Holding

B.V./HAL Allergie GmbH, Bencard Allergie GmbH/Allergy Therapeutics, Lofarma, grants and personal fees from ASIT Biotech Tools S.A., Laboratorios LETI/LETI Pharma, Anergis S.A., GlaxoSmithKline, personal fees from Astellas Pharma Global, personal fees from EUFOREA, ROXALL Medizin, Novartis, Sanofi-Aventis and Sanofi-Genzyme, Med Update Europe GmbH, streamedup! GmbH, Mobile Chamber Experts (a GA2LEN Partner), Indoor Biotechnologies, MEDA Pharma/MYLAN, John Wiley and Sons, AS, Paul-Martini-Stiftung (PMS), Ingress-Health HWM, Regeneron Pharmaceuticals Inc., grants from Pohl-Boskamp, Immunotek S.L., Biomay, Circassia. JS reports grants and personal fees from SANOFI, personal fees from GSK, NOVARTIS, ASTRA ZENECA, MUNDIPHARMA, FAES FARMA. AMTB reports grants and personal fees from Novartis, Mundipharma, Teva Pharma, GSK (GlaxoSmithKline), AstraZeneca, grants from Leti, personal fees from BIAL. Dr. Tsiligianni reports personal fees from Honoraria for educational activities, speaking engagements, advisory boards from Boehringer Ingelheim, Astra Zeneca, GSK, Novartis, MSD and grants from GSK Hellas Astra Zeneca, and Elpen. DW reports personal fees from ALK.

## AUTHOR CONTRIBUTIONS

BSP participated in methodology, formal analysis and writing - original draft. OP participated in conceptualisation, formal analysis, supervision and writing - original draft. LFA participated in methodology and writing - review & editing. JAF participated in conceptualisation, formal analysis, supervision and writing - review & editing. JB participated in conceptualisation, formal analysis, supervision and writing - original draft. All remaining authors participated in data collection and writing - review & editing.
