# An efficient certificateless two-party authenticated key agreement protocol 

Debiao He ${ }^{1}$ Sahadeo Padhye ${ }^{2}$, Jianhua Chen ${ }^{1, *}$<br>${ }^{1}$ School of Mathematics and Statistics, Wuhan University, Wuhan, China<br>${ }^{2}$ Motilal Nehru NAtional Institute of Technology, Allahabad, India<br>*Email: chenjianhua.math@gmail.com

#### Abstract

Due to avoiding the key escrow problem in the identity-based cryptosystem, certificateless public key cryptosystem (CLPKC) has received a significant attention. As an important part of the CLPKC, the certificateless authenticated key agreement (CLAKA) protocol also received considerable attention. Most CLAKA protocols are built from bilinear mappings on elliptic curves which need costly operations. To improve the performance, several pairing-free CLAKA protocols have been proposed. In this paper we propose a new pairing-free CLAKA protocol. Compared with the related protocols our protocol has better performance. We also show our protocol is provably secure in a very strong security model, i.e. the extended CanettiKrawczyk (eCK) model.

Key words: Certificateless cryptography; Authenticated key agreement; Provable security; Bilinear pairings; Elliptic curve

Classification Codes: 11T71, 94A60

## 1. Introduction

To realize information security, the public key cryptography has been widely used in networks communications. In the traditional public key cryptography (PKC), there is a need for certificate to assurance to the user about the relationship between a public key and the identity of the holder of the corresponding private key. So there come the problems of certificate management, including revocation, storage, distribution etc. [1]. To solve the above problem, Shamir introduced the concept of identity-based cryptography (ID-PKC) [2]. In ID-PKC setting, a user's public key can be derived from his identity (e.g., his name or email address) and his secret key is generated by the Key Generation Center ( KGC). Then there come the key escrow problem, i.e. the PKG knows all the user’s secret keys. In 2003, Al-Riyami et al. [3] proposed the certificateless public key cryptography (CLPKC) to solve the key escrow problem. Since then the CLPKC received a significant attention.

After Al-Riyami et al.'s work [3], numerous certificateless authenticated key agreement (CLAKA) protocols, using bilinear mappings on elliptic curves, have been proposed, e.g., [4-10]. However, the relative computation cost of a pairing is approximately twenty times higher than that of the scalar multiplication over elliptic curve group [11]. Therefore, CLAKA protocols without bilinear pairings would be more appealing in terms of efficiency. Recently, several CLAKA protocols without pairing have been proposed in [12-15]. Yang et al. [14] pointed out that neither Geng et al.'s protocol [14], nor Hou et al.'s protocol [13] is secure. He et al. [15] also proposed a CLAKA protocol without pairing. However, He et al.'s protocol is vulnerable to the type 1 adversary [16]. Although the latest CLAKA protocol [16] is more efficient than other protocols [12-15], it is provably secure under the mBR model [17], which is a very weak model. Yang et al. have shown that their scheme is provably secure in a very strong model-the extended Canetti-Krawczyk (eCK) model [18]. However, the user in Yang et al.’ protocol needs nine elliptic curve scalar multiplications to finish the key agreement. Moreover, the user has to verify the validity of public keys. This not only increases the burden of the user, but also reverses the thought of CLPKC. In this paper, we will propose a new pairing-free CLAKA protocol, which is provably secure in the eCK model. Besides, our protocol has better performance than the related protocols.

The remainder of this paper is organized as follows. Section 2 describes some preliminaries. In Section 3, we propose our CLAKA protocol. The security analysis of the proposed protocol is presented in Section 4. In Section 5, performance analysis is presented. Finally, in Section 6 we conclude the paper.

## 2. Preliminaries

### 2.2. Notations

In this subsection, we first introduce some notations as follows, which are used in this paper.

- $p, n$ : two large prime numbers;
- $F_{p}$ : a finite field;
- $E / F_{p}$ : an elliptic curve defined on $F_{p}$;
- $G$ : the cyclic additive group composed of the points on $E / F_{p}$;
- $\quad P$ : a generator of $G$;
- $H_{1}(\cdot)$ : a secure one-way hash function, where $H_{1}:\{0,1\}^{*} \times G \rightarrow Z_{n}^{*}$;
- $H_{2}(\cdot)$ : a secure one-way hash function, where $H_{2}:\{0,1\}^{*} \times\{0,1\}^{*} \times G \times G \times G \times G \times G \rightarrow Z_{p}^{*}$;
- $I D_{i}$ : the identity of user $i$;
- $\left(x, P_{\text {pub }}\right)$ : the KGC's private/public key pair, where $P_{p u b}=x P$;
- $\left(x_{i}, P_{i}\right)$ : the user $i$ 's secret value/public key pair, where $P_{i}=x_{i} \cdot P$;
- $\left(r_{i}, R_{i}\right)$ : a random point generated by KGC, where $R_{i}=r_{i} \cdot P$;
- $\left(s_{i}, R_{i}\right)$ : the user $i$ 's partial private key, where $s_{i}=r_{i}+h_{i} x \bmod n$, $h_{i}=H_{1}\left(I D_{i}, R_{i}\right) ;$
- $\left(t_{i}, T_{i}\right)$ : the user $i$ 's ephemeral private/public key pair, where $T_{i}=t_{i} \cdot P$;

### 2.1. Background of elliptic curve group

Let the symbol $E / F_{p}$ denote an elliptic curve $E$ over a prime finite field $F_{p}$, defined by an equation

$$
\begin{equation*}
y^{2}=x^{3}+a x+b, \quad a, b \in F_{p} \tag{1}
\end{equation*}
$$

and with the discriminant

$$
\begin{equation*}
\Delta=4 a^{3}+27 b^{2} \neq 0 . \tag{2}
\end{equation*}
$$

The points on $E / F_{p}$ together with an extra point $O$ called the point at infinity form a group

$$
\begin{equation*}
G=\left\{(x, y): x, y \in F_{p}, E(x, y)=0\right\} \bigcup\{O\} . \tag{3}
\end{equation*}
$$

$G$ is a cyclic additive group in the point addition " + " defined as follows: Let $P, Q \in G, l$ be the line containing $P$ and $Q$ (tangent line to $E / F_{p}$ if $P=$ $Q$ ), and $R$, the third point of intersection of $l$ with $E / F_{p}$. Let $l^{\prime}$ be the line connecting $R$ and $O$. Then $P$ " + " $Q$ is the point such that $l$ ' intersects $E / F_{p}$ at $R$ and $O$. Scalar multiplication over $E / F_{p}$ can be computed as follows:

$$
\begin{equation*}
t P=P+P+\cdots+P(t \text { times }) \tag{4}
\end{equation*}
$$

Let the order of $G$ be $n$. The following problems are commonly used in the security analysis of many cryptographic protocols.

Computational Diffie-Hellman (CDH) problem: Given a generator $P$ of $G$ and $(a P, b P)$ for unknown $a, b \in_{R} Z_{n}^{*}$, the task of CDH problem is to compute $a b P$.

For convenience, we define the function $c d h$ as $c d h(a P, b P)=a b P$
Decisional Diffie-Hellman (DDH) problem: Given a generator $P$ of $G$ and ( $a P, b P, c P$ ) for unknown $a, b, c \in_{R} Z_{n}^{*}$, the task of DDH problem is to decide whether the equation $a b P=c P$ holds.

Gap Diffie-Hellman (GDH) problem: Given a generator $P$ of $G$, $(a P, b P)$ for unknown $a, b \in_{R} Z_{n}^{*}$ and an oracle $\mathcal{O}_{\text {ddhp }}$, the task of GDH problem is to compute $a b P$, where $\mathcal{O}_{\text {dahp }}$ is a decision oracle that on input $(a P, b P$, $c P$ ), answers 1 if $c d h(a P, b P)=c P$; answers 0 , otherwise.

The GDH assumption states that the probability of any polynomial-time algorithm to solve the GDH problem is negligible.

### 2.2. CLAKA protocol

A CLAKA protocol consists of six polynomial-time algorithms [2, 8]: Setup , Partial-Private-Key-Extract , Set-Secret-Value , Set-Private-Key , Set-Public-Key and Key-Agreement . These algorithms are defined as follows.

Setup: This algorithm takes security parameter $k$ as input and returns the system parameters params and master key.

Partial-Private-Key-Extract: This algorithm takes params, master key, a user's identity $I D_{i}$ as inputs and returns a partial private key.

Set-Secret-Value: This algorithm takes params and a user's identity $I D_{i}$ as inputs, and generates a secret value.

Set-Private-Key: This algorithm takes params, a user's partial private key and his secret value as inputs, and outputs the full private key.

Set - Public - Key: This algorithm takes params and a user's secret value as inputs, and generates a public key for the user.

Key-Agreement : This is a probabilistic polynomial-time interactive algorithm which involves two entities $A$ and $B$, if the protocol does not fail, $A$ and $B$ will obtain a secret session key.

### 2.3. Security model for CLAKA protocols

In CLAKA scheme, there are two types of adversaries with different capabilities [9, 14]. The type 1 adversary $\mathscr{\mathscr { C }} 1$ acts as a dishonest user while the type 2 adversary $\mathscr{Z} 2$ acts as a malicious key generation center (KGC). $\mathscr{\mathscr { t }} 1$ does not know the master key, but $\mathscr{\mathscr { C }} 1$ can replace the public keys of any entity with a value of his choice. $\mathscr{C} 2$ knows the master key, but he cannot replace any user's public key.

Let $\prod_{i, j}^{s}$ represents the $s$ th session which runs at party $i$ with intended partner party $j$. A session $\prod_{i, j}^{s}$ enters an accepted state when it computes a session key $S K_{i, j}^{s}$. Two sessions $\Pi_{i, j}^{s}$ and $\prod_{j, i}^{t}$ are called matching if they have the same session identity.

Lippold et al. [9] transformed original eCK model [18] from the traditional PKI-based setting to the CLPKC setting. The eCK model in the CLPKC setting is defined by the following game between a challenger $\mathcal{G}$ and an adversary $\mathscr{A} \in\{\mathscr{\mathscr { t }} 1, \mathscr{C} 2\}$. The game runs in two phases. During the first phase, the adversary $\mathscr{\mathscr { t }}$ is allowed to issue the following queries in any order:

Create(i): On receiving such a query, $\mathbb{T}$ generates the public/private key pair for participant $i$ with identity $I D_{i}$.

RevealMasterKey: $\mathbb{G}$ gives the master secret key to $\mathscr{\mathscr { A }}$.
RevealSessionKey $\left(\Pi_{i, j}^{s}\right)$ : If the session has not been accepted, $\mathcal{G}$ returns $\perp$ to $\mathscr{\mathscr { t }}$. Otherwise G reveals the accepted session key to $\mathscr{\mathscr { t }}$.

RevealPartialPrivateKey(i): $\mathcal{G}$ returns participant i’s partial private key to $\mathscr{O}$.

RevealSecretValue(i): Treturns participant i's secret value to $\mathscr{\mathscr { t }}$.
ReplacePublicKey(i,pk): $G$ replaces participant $i$ 's public key with the value chose by $\mathscr{\mathscr { t }}$.

RevealEphemeralKey $\left(\prod_{i, j}^{s}\right)$ : $\tau$ returns participant $i$ ’s ephemeral private key to $\mathscr{A}$.

Send $\left(\prod_{i, j}^{s}, m\right)$ : The adversary sends the message $m$ to the session $\prod_{i, j}^{s}$ and get a response according to the protocol specification.

Once the adversary $\mathscr{\mathscr { t }}$ decides that the first phase is over, it starts the second phase by choosing a fresh session $\prod_{i, j}^{s}$ and issuing a $\operatorname{Test}\left(\prod_{i, j}^{s}\right)$ query, where the fresh session and test query are defined later.

The type 1 adversary $\mathscr{\mathscr { C }} 1$ could get any user's secret value, since he can replace the public key of any entity with a value of his choice. The type 2 adversary $\mathscr{\mathscr { t }} 2$ could get any user's partial private key since he has access to the master key. Then several cases do not exist in Lippold et al.'s model [9]. To get better performance, we define the definition of freshness for CLAKA scheme against two type of adversary as follows.

Definition 1 (Freshness for CLAKA Scheme against Type 1 Adversary). Let instance $\prod_{i, j}^{s}$ be a completed session, which is executed by an honest party $i$ with another honest party $j$. We define $\prod_{i, j}^{s}$ to be fresh if none of the following three conditions hold:

- The adversary $\mathscr{\mathscr { t }} 1$ reveals the session key of $\prod_{i, j}^{s}$ or of its matching session (if the latter exists).
- $\quad j$ is engaged in $\Pi_{j, i}^{t}$ the session matching to $\Pi_{i, j}^{s}$ and $\mathscr{\mathscr { O }} 1$ either reveals both of $i$ 's partial private key and $\Pi_{i, j}^{s}$ 's ephemeral private key or both of $j$ 's partial private key and $\Pi_{j, i}^{t}$ 's ephemeral private key.
- No sessions matching to $\prod_{i, j}^{s}$ exist and $\mathscr{\mathscr { Z }} 1$ either reveals both of $i$ 's partial private key and $\Pi_{i, j}^{s}$ 's ephemeral private key or $j$ 's partial private key.

Definition 2 (Freshness for CLAKA Scheme against Type 2 Adversary). Let instance $\prod_{i, j}^{s}$ be a completed session, which is executed by an honest party $i$ with another honest party $j$. We define $\prod_{i, j}^{s}$ to be fresh if none of the following three conditions hold:

- The adversary $\mathscr{\mathscr { Z }} 2$ reveals the session key of $\Pi_{i, j}^{s}$ or of its matching session (if the latter exists).
- $\quad j$ is engaged in $\Pi_{j, i}^{t}$ the session matching to $\Pi_{i, j}^{s}$ and $\mathscr{\mathscr { t }} 2$ either reveals both of $i$ 's secret value and $\Pi_{i, j}^{s}$ 's ephemeral private key or both of $j$ 's secret value and $\prod_{j, i}^{t}$ 's ephemeral private key.
- No sessions matching to $\Pi_{i, j}^{s}$ exist and $\mathscr{\mathscr { t } 2}$ either reveals both of $i$ 's secret value and $\Pi_{i, j}^{s}$ 's ephemeral private key or $j$ 's partial private key.
$\operatorname{Test}\left(\prod_{i, j}^{s}\right)$ : At some point, $\mathfrak{c t}$ may choose one of the oracles, say $\prod_{i, j}^{s}$, to ask a single Test query. This oracle must be fresh. To answer the query, the oracle flips a fair coin $b \in\{0,1\}$, and returns the session key held by $\prod_{i, j}^{s}$ if $b=0$, or a random sample from the distribution of the session key if $b=1$.

At the end of the game, $\mathscr{\mathscr { t }}$ must output a guess bit $b^{\prime}$. $\mathscr{t}$ wins if and only if $b^{\prime}=b . \mathscr{\mathscr { t }}$ 's advantage to win the above game, denoted by $A d v_{\mathscr{\mathscr { t }}}(k)$, is defined as: $A d v_{\tilde{z} t}(k)=\left|\operatorname{Pr}\left[b^{\prime}=b\right]-\frac{1}{2}\right|$, where $k$ is a security parameter.

Definition 3. A CLAKA scheme is said to be secure if:
(1) In the presence of a benign adversary on $\prod_{i, j}^{s}$ and $\prod_{j, i}^{t}$, both oracles always agree on the same session key, and this key is distributed uniformly at random.
(2) For any adversary $\mathscr{\mathscr { t }} \in\left\{\mathscr{C}_{\mathscr{A}} 1, \mathscr{\mathscr { C }} 2\right\}, \quad \operatorname{Adv} v_{\mathscr{\mathscr { t }}}(k)$ is negligible.

## 3. Our protocol

In this section, we will propose a new CLAKA protocol based on previous works [9, 14, 16]. Our protocol consists of six polynomial-time algorithms. They are described as follows.

Setup: This algorithm takes a security parameter $k$ as an input, returns system parameters and a master key. Given $k$, KGC does the following steps.

1) KGC chooses a $k$-bit prime $p$ and determines the tuple $\left\{F_{p}, E / F_{p}, G, P\right\}$ as defined in Section 2.1.
2) KGC chooses the master private key $x \in Z_{n}^{*}$ and computes the master public key $P_{\text {pub }}=x P$.
3) KGC chooses two cryptographic secure hash functions $H_{1}:\{0,1\}^{*} \times G \rightarrow Z_{n}^{*}$ and $H_{2}:\{0,1\}^{*} \times\{0,1\}^{*} \times G \times G \times G \times G \times G \times G \rightarrow Z_{n}^{*}$.
4) KGC publishes params $=\left\{F_{p}, E / F_{p}, G, P, P_{\text {pub }}, H_{1}, H_{2}\right\}$ as system parameters and keeps the master key $x$ secretly.

Partial-Private-Key-Extract: This algorithm takes master key, a user's identifier, system parameters as inputs, and returns the user's ID-based private key. KGC works as follows.

1) KGC chooses a random number $r_{i} \in Z_{n}^{*}$, computes $R_{i}=r_{i} \cdot P$ and $h_{i}=H_{1}\left(I D_{i}, R_{i}\right)$.
2) KGC computes $s_{i}=r_{i}+h_{i} x \bmod n$ and issues $\left(s_{i}, R_{i}\right)$ to the users through secret channel.

Set-Secret-Value : The user picks randomly $x_{i} \in Z_{n}^{*}$, computes $P_{i}=x_{i} \cdot P$ and sets $x_{i}$ as his secret value.

Set-Private-Key: The user with identity $I D_{i}$ takes the pair $s k_{i}=\left(x_{i}, s_{i}\right)$ as its private key.

Set-Public-Key: The user with identity $I D_{i}$ takes $p k_{i}=\left(P_{i}\right)$ as its public key.

Key-Agreement: Assume that an entity $A$ with identity $I D_{A}$ has private key $s k_{A}=\left(x_{A}, s_{A}\right)$ and public key $p k_{A}=\left(P_{A}\right)$ and an entity $B$ with identity $I D_{B}$ has private key $s k_{B}=\left(x_{B}, s_{B}\right)$ and public key $p k_{B}=\left(P_{B}\right)$ want to establish a session key, they can do, as shown in Fig.1, as follows.

1) $A$ chooses a random number $t_{A} \in Z_{n}^{*}$ and computes $T_{A}=t_{A} \cdot P$, then $A$ sends $M_{1}=\left\{I D_{A}, R_{A}, T_{A}\right\}$ to $B$.
2) After receiving $M_{1}, B$ chooses a random number $t_{B} \in Z_{n}^{*}$ and computes $T_{B}=t_{B} \cdot P$, then $B$ sends $M_{2}=\left\{I D_{B}, R_{B}, T_{B}\right\}$ to $A$.

Then both $A$ and $B$ can compute the shared secrets as follows:
A computes

$$
\begin{align*}
& K_{A B}^{1}=\left(t_{A}+s_{A}\right)\left(T_{B}+R_{B}+H_{1}\left(I D_{B}, R_{B}\right) P_{p u b}\right)  \tag{5}\\
& K_{A B}^{2}=\left(t_{A}+x_{A}\right)\left(T_{B}+P_{B}\right) \tag{6}
\end{align*}
$$

and

$$
\begin{equation*}
K_{A B}^{3}=t_{A} \cdot T_{B} \tag{7}
\end{equation*}
$$

$B$ computes

$$
\begin{align*}
& K_{B A}^{1}=\left(t_{B}+s_{B}\right)\left(T_{A}+R_{A}+H_{1}\left(I D_{A}, R_{A}\right) P_{p u b}\right)  \tag{8}\\
& K_{B A}^{2}=\left(t_{B}+x_{B}\right)\left(T_{A}+P_{A}\right) \tag{9}
\end{align*}
$$

and

$$
\begin{equation*}
K_{B A}^{3}=t_{B} \cdot T_{A} \tag{10}
\end{equation*}
$$

Thus the agreed session key for $A$ and $B$ can be computed as:

$$
\begin{align*}
& s k=H_{2}\left(I D_{A}\left\|I D_{B}\right\| T_{A}\left\|T_{B}\right\| K_{A B}^{1}\left\|K_{A B}^{2}\right\| K_{A B}^{3}\right) \\
& =H_{2}\left(I D_{A}\left\|I D_{B}\right\| T_{A}\left\|T_{B}\right\| K_{B A}^{1}\left\|K_{B A}^{2}\right\| K_{B A}^{3}\right) \tag{11}
\end{align*}
$$

Generate a random number $t_{A} ; \quad M_{1}=\left\{I D_{A}, R_{A}, T_{A}\right\} \quad$ Generate a random number $t_{B}$;
$T_{A}=t_{A} \cdot P ; \quad \xrightarrow{M} M_{B}=\left\{I D_{A}, R_{A}, T_{A}\right\} \longrightarrow t_{B} \cdot P$,

Fig. 1. Key agreement of our protocol
Since $T_{A}=t_{A} \cdot P, P_{A}=x_{A} \cdot P, s_{A} P=R_{A}+H_{1}\left(I D_{A}, R_{A}\right) P_{p u b}, T_{B}=t_{B} \cdot P$, $P_{B}=x_{B} \cdot P$ and $s_{B} P=R_{B}+H_{1}\left(I D_{B}, R_{B}\right) P_{p u b}$, then we have

$$
\begin{align*}
& K_{A B}^{1}=\left(t_{A}+s_{A}\right)\left(T_{B}+R_{B}+H_{1}\left(I D_{B}, R_{B}\right) P_{p u b}\right) \\
& =\left(t_{A}+s_{A}\right)\left(t_{B}+s_{B}\right) P=\left(t_{B}+s_{B}\right)\left(t_{A}+s_{A}\right) P  \tag{12}\\
& =\left(t_{B}+s_{B}\right)\left(T_{A}+R_{A}+H_{1}\left(I D_{A}, R_{A}\right) P_{p u b}\right)=K_{B A}^{1} \\
& K_{A B}^{2}=\left(t_{A}+x_{A}\right)\left(T_{B}+P_{B}\right) \\
& =\left(t_{A}+x_{A}\right)\left(t_{B}+x_{B}\right) P=\left(t_{B}+x_{B}\right)\left(t_{A}+x_{A}\right) P  \tag{13}\\
& =\left(t_{B}+x_{B}\right)\left(T_{A}+P_{A}\right)=K_{B A}^{2}
\end{align*}
$$

and

$$
\begin{equation*}
K_{A B}^{3}=t_{A} t_{B} P=t_{B} t_{A} P=K_{B A}^{3} \tag{14}
\end{equation*}
$$

Thus, the correctness of the protocol is proved.

## 4. Security Analysis

In this section, we will show our scheme is provably secure in eCK model. We treat $H_{1}$ and $H_{2}$ as two random oracles [19]. For the security, the following lemmas and theorems are provided.

Lemma 1. If two oracles are matching, both of them will be accepted and will get the same session key which is distributed uniformly at random in the session key sample space.

Proof. From the correction analysis of our protocol in Section 3, we know if two oracles are matching, then both of them are accepted and have the same session key. The session keys are distributed uniformly since $t_{A}$ and $t_{B}$ are selected uniformly during the execution.

Lemma 2. Assuming that the GDH problem is intractable, the advantage of a type 1 adversary against our protocol is negligible.

Proof. Suppose that there is a type 1 adversary $\mathscr{\mathscr { t }} 1$ who can win the game defined in subsection 2.3 with a non-negligible advantage $A d v_{\mathscr{\mathscr { f } 1} 1}(k)$ in polynomial-time $t$. Then, we will show how to use the ability of $\mathscr{\mathscr { A }} 1$ to construct an algorithm $\tau$ to solve the GDH problem.

Let $n_{0}$ be the maximum number of sessions that any one party may have. Assume that the adversary $\mathscr{\mathscr { t }} 1$ activates at most $n_{1}$ distinctive honest parties. Assume that the adversary $\mathscr{\mathscr { C }} 1$ activates at most $n_{2}$ distinctive hash queries. Assume also that $A d v_{\mathfrak{z} t 1}(k)$ is non-negligible. Before the game starts, $\mathcal{G}$ tries to guess the test session and the strategy that the adversary $\mathscr{C} 1$ will adopt. 飞 randomly selects two indexes $I, J \in\left\{1, \cdots, n_{1}\right\}: I \neq J$, which represent the $I$ th and the $J$ th distinct honest party that the adversary initially chooses. Also, $\mathcal{G}$ chooses $S \in\left\{1, \cdots, n_{0}\right\}$ and determines the Test session $\Pi_{I, J}^{S}$, which is correct with probability larger than $\frac{1}{n_{0} n_{1}^{2}}$. Let $\Pi_{J, I}^{T}$ be the matching session of $\Pi_{I, J}^{S}$. Since $H_{1}$ and $H_{2}$ are modeled as random oracles, after the adversary issues the test query, it has only three possible ways to distinguish the tested session key from a random string:

CASE 1: Forging attack: Assume that $\prod_{I, J}^{S}$ is the test session. At some point in its run, the adversary $\mathscr{\mathscr { C }} 1$ queries $H_{2}$ on the value $\left(I D_{I}, I D_{J}, T_{I}, T_{J}, K_{I J}^{1}, K_{I J}^{2}, K_{I J}^{3}\right)$ in the test session owned by $I$ communicating with $J$. Clearly, in this case $\mathscr{\mathscr { t }} 1$ computes the values $K_{I I}^{1}$, $K_{I J}^{2}$ and $K_{I J}^{3}$ itself.

CASE 2: Guessing attack: $\mathscr{\mathscr { t }} 1$ correctly guesses the session key.
CASE 3: Key-replication attack: The adversary $\mathscr{\mathscr { H }} 1$ forces a nonmatching session to have the same session key with the test session. In this case,
the adversary $\mathscr{\mathscr { t }} 1$ can simply learn the session key by querying the nonmatching session.

Since $\mathrm{H}_{2}$ is a random oracle, the probability of guessing the output of $\mathrm{H}_{2}$ is $O\left(1 / 2^{k}\right)$, which is negligible. The input to the key derivation function $\mathrm{H}_{2}$ includes all information that can uniquely identify the matching sessions. Since two non-matching sessions can not have the same identities and the same ephemeral public keys and $\mathrm{H}_{2}$ is modeled as a random oracle, the success probability of Key-replication attack is also negligible. Thus Guessing attack and Key-replication attack can be ruled out, and the rest of the proof is mainly devoted to the analysis of Forging attack. As the attack that the adversary $\mathscr{\mathscr { t }} 1$ mounts is Forging attack, $\mathscr{t} 1$ can not get an advantage in winning the game against the protocol unless it queries the $\mathrm{H}_{2}$ oracle on the session key.

The rest of this section is mainly devoted to the analysis of the Forging attack. To relate the advantage of the adversary $\mathscr{\mathscr { H }} 1$ against our protocol to the GDH assumption, we use a classical reduction approach. In the following, a challenger $\mathbb{G}$ is interested to use the adversary $\mathscr{\mathscr { C }} 1$ to turn $\mathscr{\mathscr { C }} 1$ 's advantage in distinguishing the tested session key from a random string into an advantage in solving the GDH problem. The following two sub-cases should be considered.

CASE 1.1: No honest party owns a matching session to the Test session.
CASE 1.2: The Test session has a matching session owned by another honest party.

## > The analysis of CASE 1.1:

Since $\mathscr{\mathscr { C }} 1$ is strong type 1 adversary, then he can get any users' secret key $x_{i}$ value through ReplacePublicKey query. According to Definition 1, $\mathcal{G}$ has the following two choices for $\mathscr{\mathscr { Z }} 1$ 's strategy:

CASE 1.1.1: At some point, the partial private key of party $I$ has been revealed by the adversary $\mathscr{\mathscr { C }} 1$. According to Definition 1, $\mathscr{\mathscr { C }} 1$ is not permitted to reveal the ephemeral private key of the Test session.

CASE 1.1.2: The partial private key of party $I$ has never been revealed by the adversary $\mathscr{\mathscr { t }} 1$. According to Definition 1, $\mathscr{\mathscr { C }} 1$ may reveal the ephemeral private key of the Test session.

CASE 1.1.1:

Let $A d v_{\widetilde{G}}^{G D H}(k)$ be the advantage that the challenger $\mathcal{T}$ gets in solving the GDH problem given the security parameter $k$. Given a GDH problem instance $\left(U=u P, V=v P, \mathcal{O}_{\text {dahp }}\right)$ and $\tau$ 's task is to compute $c d h(U, V)=u v P$, where $\mathcal{O}_{\text {ddhp }}$ is a decision oracle that on input ( $a P, b P, c P$ ), answers 1 if $c d h(a P, b P)=c P$; answers 0 , otherwise. $G$ first chooses $P_{0} \in G$ at random, sets $P_{0}$ as the system public key $P_{p u b}$, selects the system parameter params $=\left\{F_{p}, E / F_{p}, G, P, P_{p u b}, H_{1}, H_{2}\right\}$, and sends params to $\mathscr{\mathscr { A }} 1$. Then, $\mathcal{G}$ simulates the game outlined in Section 2.3 as follows.

Create(i): $\mathcal{T}$ maintains an initially empty list $L_{C}$ consisting of tuples of the form $\left(I D_{i}, s_{i}, R_{i}, x_{i}, P_{i}\right)$. If $i=J, \tau$ chooses two random numbers $h_{i}, x_{i} \in Z_{n}^{*}$, computes $R_{i}=U-h_{i} P_{0}, P_{i}=x_{i} P$, sets $H_{1}\left(I D_{i}, R_{i}\right) \leftarrow h_{i}$ and stores ( $I D_{i}, \perp, R_{i}, x_{i}, P_{i}$ ) and ( $I D_{i}, R_{i}, h_{i}$ ) in $L_{C}$ and $L_{H_{1}}$ separately. Otherwise, $\mathcal{G}$ chooses three random numbers $s_{i}, h_{i}, x_{i} \in Z_{n}^{*}$, computes $R_{i}=s_{i} P-h_{i} P_{p u b}, P_{i}=x_{i} P$, sets $H_{1}\left(I D_{i}, R_{i}\right) \leftarrow h_{i}$ and stores $\left(I D_{i}, s_{i}, R_{i}, x_{i}, P_{i}\right)$ and $\left(I D_{i}, R_{i}, h_{i}\right)$ in $L_{C}$ and $L_{H_{1}}$ separately.
$H_{1}\left(I D_{i}, R_{i}\right): \tau$ maintains an initially empty list $L_{H_{1}}$ which contains tuples of the form $\left(I D_{i}, R_{i}, h_{i}\right)$. If ( $I D_{i}, R_{i}$ ) is on the list $L_{H_{1}}$, Є returns $h_{i}$. Otherwise, $\tau$ chooses a random number $h_{i}$, stores $\left(I D_{i}, R_{i}, h_{i}\right)$ in $L_{H_{1}}$ and returns $h_{i}$.
$H_{2}\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right): \tau$ maintains an initially empty list $L_{H_{2}}$ with entries of the form ( $\left.I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right)$. If the tuple is in the list $L_{H_{2}}, \mathcal{G}$ responds with $s k$. Otherwise, $\mathcal{G}$ responds to these queries in the following way:

- If $I D_{i}=I D_{J}$,
- $\mathcal{G}$ looks the list $L_{S}$ for entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, *\right)$. If $\tau$ finds the entry, he computes $\bar{Z}_{1}=Z_{1}-t_{i}\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right)\right)-s_{j}\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right)\right)$.
- Then $\mathbb{G}$ checks whether $Z_{1}$ is correct by checking whether the oracle $\mathcal{O}_{\text {dahp }}$ outputs 1 when the tuple $\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right) P_{\text {pub }}, T_{j}, \bar{Z}_{1}\right)$ is
inputted. $\mathcal{G}$ also checks whether $Z_{2}$ and $Z_{3}$ are equal by checking if the equations $Z_{2}=\left(t_{i}+x_{i}\right)\left(T_{j}+P_{j}\right)$ and $Z_{3}=t_{i} T_{j}$ hold separately. If $Z_{1}, Z_{2}$ and $Z_{3}$ are correct, $\tau$ stores the tuple $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right)$ into $L_{H_{2}}$, where the value $s k$ comes from $L_{s}$. Otherwise, $\mathcal{G}$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk ) into $L_{H_{2}}$.
- Otherwise,
- $\mathcal{G}$ looks up the list $L_{S}$ for entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, *\right)$. If $\mathcal{G}$ finds the entry, he stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk) into $L_{H_{2}}$, where the value $s k$ comes from $L_{S}$.
- Otherwise, $G$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right)$ into $L_{H_{2}}$.
RevealPartialPrivateKey(i): $\mathcal{G}$ answers $\mathscr{Z} 1$ 's queries as follows.
- If $I D_{i}=I D_{J}$ then $\tau$ stops the simulation.
- Otherwise, $\mathcal{G}$ looks up the list $L_{E}$ and returns the corresponding partial private key $s_{i}$ to the adversary $\mathscr{\mathscr { C }} 1$.

RevealSecretValue(i): $\mathcal{G}$ looks up the table $L_{C}$ for entry ( $\left.I D_{i},{ }^{*},{ }^{*}, *, *\right)$. If
$\tau$ finds the entry, he returns $x_{i}$. Otherwise, $\mathcal{G}$ carries out the query Create(i) and returns the corresponding $x_{i}$.

ReplacePublicKey(i,pk): Upon receiving the query, $\mathcal{G}$ looks up the table $L_{C}$ for entry $\left(I D_{i},{ }^{*}, *,{ }^{*}, *\right)$. If $\tau$ finds the entry, he replaces $x_{i}$ and $P_{i}$ with $x_{i}^{\prime}$ and $P_{i}^{\prime}$ separately, where $p k=\left(P_{i}^{\prime}\right)$ and $P_{i}^{\prime}=x_{i}^{\prime} P$. Otherwise, $\mathcal{G}$ carries out Create(i) and replaces $x_{i}$ and $P_{i}$ with $x_{i}^{\prime}$ and $P_{i}^{\prime}$ separately.

RevealEphemeralKey $\left(\Pi_{i, j}^{s}\right): \tau$ answers $\mathscr{\mathscr { L }} 1$ 's queries as follows.

- If $\prod_{i, j}^{s}=\prod_{I, J}^{s}$, then $\tau$ stops the simulation.
- Otherwise, 飞 returns the stored ephemeral private key to $\mathscr{\mathscr { Z }} 1$.

RevealMasterKey: $\mathcal{G}$ stops the simulation.
RevealSessionKey $\left(\Pi_{i, j}^{s}\right): \tau$ answers $\check{\mathscr{t}} 1$ 's queries as follows.

- If $\Pi_{i, j}^{s}=\Pi_{I, J}^{S}$ or $\Pi_{i, j}^{s}=\Pi_{J, I}^{T}$, then $\mathcal{G}$ stops the simulation.
- Otherwise, if $G$ returns the session key sk to $\mathscr{\mathscr { C }} 1$.
$\operatorname{Send}\left(\prod_{i, j}^{t}, m\right): \mathcal{G}$ maintains an initially empty list $L_{S}$ with entries of the form ( $I D_{i}, I D_{j}, T_{i}, T_{j}, s k$ ) and answers $\mathscr{\mathscr { t }} 1$ 's queries as follows.
- If $\prod_{i, j}^{t}=\prod_{I, J}^{S}$, then $G$ returns $T_{i}=V$ to $\mathscr{C} 1$.
- Otherwise, if $I D_{i}=I D_{J}$, he generates a random $t_{i} \in Z_{n}$, computes $\bar{Z}_{1}=Z_{1}-t_{i}\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right)\right)-s_{j}\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right)\right)$. Then $\tau$ checks whether $Z_{1}$ is correct by checking whether the oracle $\mathcal{O}_{\text {ddhp }}$ outputs 1 when the tuple $\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right) P_{p u b}, T_{j}, \bar{Z}_{2}\right)$ is inputted. $\mathcal{G}$ also checks whether $Z_{2}$ and $Z_{3}$ are equal by checking whether the equations $Z_{2}=\left(t_{i}+x_{i}\right)\left(T_{j}+P_{j}\right)$ and $Z_{3}=t_{i} T_{j}$ hold separately. If $Z_{1}, Z_{2}$ and $Z_{3}$ are correct, $\tau$ stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, s k$ ) into $L_{s}$, where the value $s k$ comes from $L_{H_{2}}$. Otherwise, $\tau$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}$, sk ) into $L_{s}$.
- Otherwise, $\mathcal{G}$ replies according to the specification of the protocol.
$\operatorname{Test}\left(\prod_{i, j}^{t}\right): \mathbb{T}$ answers $\mathscr{\mathscr { C }} 1$ 's queries as follows.
- If $\prod_{i, j}^{s} \neq \prod_{I, J}^{S}$, then $\tau$ stops the simulation.
- Otherwise, $\tau$ generates a random number $\xi \in\{0,1\}^{k}$ and returns it to $\mathscr{A} 1$.

As the adversary $\mathscr{\mathscr { C }} 1$ mounts the forging attack, if $\mathscr{\mathscr { L }} 1$ succeeds, it must have queried oracle $H_{2}$ on the form $Z_{1}=\left(t_{I}+s_{I}\right)\left(T_{J}+R_{J}+H_{1}\left(I D_{J}, R_{J}\right) P_{p u b}\right)=\left(t_{I}+s_{I}\right)\left(T_{J}+U\right)$ $Z_{2}=\left(t_{I}+x_{I}\right)\left(T_{J}+P_{J}\right)$ and $Z_{3}=t_{I} T_{J}$, where $T_{I}=V$ is the outgoing message of Test session by the simulator and $T_{J}$ is the incoming message from the adversary $\mathscr{\mathscr { t }} 1$. To solve $c d h(U, V)$, for all entries in $L_{H_{2}}$, $\tau$ randomly chooses one entry with the probability $\frac{1}{n_{2}}$ and computes

$$
\begin{align*}
& \bar{Z}_{1}=Z_{1}-t_{J}\left(T_{I}+R_{I}+H_{1}\left(I D_{I}, R_{I}\right)\right)-s_{I}\left(R_{J}+H_{1}\left(I D_{J}, R_{J}\right)\right)  \tag{16}\\
& =t_{I}\left(R_{J}+H_{1}\left(I D_{J}, R_{J}\right)\right)=c d h(U, V)
\end{align*}
$$

The advantage of $\mathcal{G}$ solving GDH problem with the advantage

$$
\begin{equation*}
A d v_{\overparen{G}}^{G D H}(k) \geq \frac{1}{n_{0} n_{1}^{2} n_{2}} A d v_{\tilde{z_{t}} 1}(k) \tag{17}
\end{equation*}
$$

Then $A d v_{\bar{G}}^{G D H}(k)$ is non-negligible since we assume that $A d v_{\tilde{f} t 1}(k)$ is nonnegligible. This contradicts the GDH assumption.

## CASE 1.1.2:

Let $A d v_{\bar{G}}^{G D H}(k)$ be the advantage that the challenger $\mathcal{G}$ gets in solving the GDH problem given the security parameter $k$. Given a GDH problem instance $\left(U=u P, V=v P, \mathcal{O}_{\text {dahp }}\right.$ ) and $\tau$ 's task is to compute $c d h(U, V)=u v P$, where $\mathcal{O}_{\text {ddhp }}$ is a decision oracle that on input ( $a P, b P, c P$ ), answers 1 if $c d h(a P, b P)=c P$; answers 0 , otherwise. $\tau$ first chooses $P_{0} \in G$ at random, sets $P_{0}$ as the system public key $P_{p u b}$, selects the system parameter params $=\left\{F_{p}, E / F_{p}, G, P, P_{p u b}, H_{1}, H_{2}\right\}$, and sends params to $\mathscr{\mathscr { L }} 1$. Then, $\mathcal{G}$ simulates the game outlined in Section 2.3 as follows. Then, $\mathcal{G}$ simulates the game outlined in Section 2.3. During the game, $\mathcal{G}$ simulates $\mathscr{\mathscr { t }} 1$ 's $H_{1}\left(I D_{i}, R_{i}\right) \quad$, RevealMasterKey , RevealSecretValue(i) , ReplacePublicKey(i,pk), RevealSessionKey $\left(\Pi_{i, j}^{s}\right)$ and $\operatorname{Test}\left(\prod_{i, j}^{s}\right)$ queries as that of CASE 1.1.1. $\mathcal{G}$ simulates other oracles as follows.

Create(i): $\mathcal{G}$ simulates the oracle in the same way as that of CASE 1.1 except for $i=I$. If $i=I, \tau$ chooses two random numbers $h_{i}, x_{i} \in Z_{n}^{*}$, computes $\quad R_{i}=V-h_{i} P_{0}, \quad P_{i}=x_{i} P \quad$ sets $\quad H_{1}\left(I D_{i}, R_{i}\right) \leftarrow h_{i} \quad$ and $\quad$ stores $\left(I D_{i}, \perp, R_{i}, x_{i}, P_{i}\right)$ and $\left(I D_{i}, R_{i}, h_{i}\right)$ in $L_{C}$ and $L_{H_{1}}$ separately.
$H_{2}\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, h\right): \tau$ simulates the oracle in the same way as that of CASE 1.1.1 except for the form ( $I D_{I}, I D_{J}, T_{I}, T_{J}, Z_{1}, Z_{2}, Z_{3}$ ) and ( $I D_{J}, I D_{I}, T_{J}, T_{I}, Z_{1}, Z_{2}, Z_{3}$ ). $\tau$ responds to these queries in the following way:

- If $\left(I D_{I}, I D_{J}, T_{I}, T_{J}, Z_{1}, Z_{2}, Z_{3}, h\right)$ or $\left(I D_{J}, I D_{I}, T_{J}, T_{I}, Z_{1}, Z_{2}, Z_{3}, h\right)$ is in $L_{H_{2}}, \tau$ responds with the stored value $h$.
- Otherwise, $\tau$ looks up the table $L_{S}$ for entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, *\right)$. If there is no such entry, $\mathcal{G}$ choose a random number $h \in\{0,1\}^{k}$ and
stores the new entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, h\right)$ in $L_{H_{2}}$. Otherwise, $\mathcal{G}$ compute $\bar{Z}_{1}=Z_{1}-t_{i}\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right)\right)-t_{j}\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right)\right)$. Then $\tau$ checks whether $Z_{1}$ is correct by checking whether the oracle $\mathcal{O}_{\text {dadp }}$ outputs 1 when the tuple $\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right) P_{p u b}, R_{j}+H_{1}\left(I D_{j}, R_{j}\right) P_{p u b}, \bar{Z}_{1}\right)$ is inputted. $\mathcal{T}$ also checks whether $Z_{2}$ and $Z_{3}$ are equal by checking if the equations $Z_{2}=\left(t_{i}+x_{i}\right)\left(T_{j}+P_{j}\right)$ and $Z_{3}=t_{i} T_{j}$ hold separately. If $Z_{1}, Z_{2}$ and $Z_{3}$ are correct, $\tau$ stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk) into $L_{H_{2}}$, where the value sk comes from $L_{s}$. Otherwise, $\mathcal{T}$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk) into $L_{H_{2}}$.

RevealPartialPrivateKey(i): $\mathbb{G}$ answers $\mathscr{\mathscr { A }} 1$ 's queries as follows.

- If $i=I$ or $i=J, \tau$ stops the simulation.
- Otherwise, $\mathcal{G}$ looks up the list $L_{C}$ and returns the corresponding partial private key $D_{i}$ to the adversary $\mathscr{\mathscr { t }} 1$.

RevealEphemeralKey $\left(\prod_{i, j}^{s}\right)$ : $\tau$ returns the stored ephemeral private key to $\mathscr{Z} 1$.
$\operatorname{Send}\left(\prod_{i, j}^{s}, m\right): \tau$ simulates the oracle in the same way as that of CASE 1.1 except for the following queries:

- If $\Pi_{i, j}^{s}=\Pi_{I, J}^{s}, \mathcal{G}$ chooses $t_{i} \in Z_{n}$ and returns $T_{i}=t_{i} P$ to $\mathscr{C} 1$.
- If $i=I$ and $j=J$ (the case that $i=J$ and $j=I$ could be deal with similarly).
- $\mathcal{G}$ chooses $t_{i} \in Z_{n}$ and returns $T_{i}=t_{i} P$ to $\mathscr{C} 1$.
$\tau$ looks up the list $L_{H_{2}}$ for entry ( $I D_{i}, I D_{j}, T_{i}, T_{j},{ }^{*},{ }^{*}, *, *$ ) (If $\Pi_{i, j}^{s}$ is responder session, $\tau$ will look up for $\left(I D_{j}, I D_{i}, T_{j}, T_{i},{ }^{*},{ }^{*}, *, *\right)$ ). If there is no such entry, $\tau$ choose a random number $s k \in\{0,1\}^{k}$ and stores the new entry ( $\left.I D_{i}, I D_{j}, T_{i}, T_{j}, s k\right)$ in $L_{S}$. Otherwise, $\mathcal{G}$ computes $\bar{Z}_{1}=Z_{1}-t_{i}\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right)\right)-t_{j}\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right)\right)$. Then $\mathcal{G}$ checks whether $Z_{1}$ is correct by checking whether the oracle $\mathcal{O}_{\text {dahp }}$
outputs 1 when the tuple $\left(R_{i}+H_{1}\left(I D_{i}, R_{i}\right) P_{\text {pub }}, R_{j}+H_{1}\left(I D_{j}, R_{j}\right) P_{p u b}, \bar{Z}_{1}\right)$ is inputted. T also checks whether $Z_{2}$ and $Z_{3}$ are equal by checking if the equations $Z_{2}=\left(t_{i}+x_{i}\right)\left(T_{j}+P_{j}\right)$ and $Z_{3}=t_{i} T_{j}$ hold separately. If all of the equations are equal, $\tau$ stores $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, h\right)$ into $L_{S}$, where $h$ comes from $L_{H_{2}}$. Otherwise, $\tau$ chooses a random number $s k$ and stores $\left(I D_{i}, I D_{j}, T_{i}, T_{j}\right.$, sk $)$ into $L_{S}$.

As the adversary $\mathscr{\mathscr { t }} 1$ mounts the forging attack, if $\mathscr{\mathscr { t }} 1$ succeeds, it must have queried oracle $H_{2}$ on the form
$Z_{1}=\left(t_{I}+s_{I}\right)\left(T_{J}+R_{J}+H_{1}\left(I D_{J}, R_{J}\right) P_{p u b}\right)=\left(t_{I}+s_{I}\right)\left(T_{J}+U\right) \quad Z_{2}=\left(t_{I}+x_{I}\right)\left(T_{J}+P_{J}\right)$ and $Z_{3}=t_{I} T_{J}$ where $T_{I}=t_{I} P$ is the outgoing message of Test session by the simulator $\mathscr{C} 1$. To solve $c d h(U, V)$, for all entries in $L_{H_{2}}, \tau$ randomly chooses one entry with the probability $\frac{1}{n_{2}}$ and computes

$$
\begin{align*}
& \bar{Z}_{1}=Z_{1}-t_{I}\left(T_{J}+R_{J}+H_{1}\left(I D_{J}, R_{J}\right)\right)-t_{J}\left(R_{I}+H_{1}\left(I D_{I}, R_{I}\right)\right)  \tag{18}\\
& =s_{I}\left(R_{J}+H_{1}\left(I D_{J}, R_{J}\right)\right)=s_{I} U=\operatorname{cdh}(U, V)
\end{align*}
$$

We can conclude that

$$
\begin{equation*}
A d v_{\bar{G}}^{G B C D H}(k) \geq \frac{1}{n_{0} n_{1}^{2} n_{2}} A d v_{\overline{\tilde{g} 1} 1}(k) \tag{19}
\end{equation*}
$$

Then $\operatorname{Adv} v_{⿷}^{G B C D H}(k)$ is non-negligible since we assume that $A d v_{\tilde{\mathscr{t}} 11}(k)$ is non-negligible. This contradicts the GCDH assumption.

## > The analysis of CASE 1.2:

In this case, the Test session $\prod_{I, J}^{S}$ has a matching session owned by another honest party $J$. According to Definition 1, the adversary $\mathscr{\mathscr { t }} 1$ has four ways to mount the attacks.

CASE 1.2.1. The adversary $\mathscr{\mathscr { t }} 1$ makes ephemeral key query to both the Test session and the matching session of the Test session (The adversary does not reveal their corresponding partial private key). In this case, the proof is identical to that of CASE 1.1.2. To save space, we omit the details.

CASE 1.2.2. The adversary $\mathscr{\mathscr { t }} 1$ makes queries to the partial private key of the owner of Test session and its peer's ephemeral private key. In this case, the proof is identical to that of CASE 1.1.1. To save space, we omit the details.

CASE 1.2.3. The adversary $\mathscr{\mathscr { C }} 1$ makes queries to the ephemeral private key of the owner of Test session and its peer's partial private key. In this case, the proof is identical to that of CASE 1.1.1. To save space, we omit the details.

CASE 1.2.4. The adversary $\mathscr{\mathscr { Z }} 1$ learns the partial private key of both the owner of Test session and its peer. (The adversary does not reveal their corresponding ephemeral private key).
$\tau$ answers $H_{1}\left(I D_{i}, R_{i}\right)$, ReplacePublicKey(i, pk), RevealSecretValue(i), RevealMasterKey RevealSessionKey $\left(\prod_{i, j}^{t}\right)$ and $\operatorname{Test}\left(\prod_{i, j}^{t}\right)$ as he does in the above case. He also answers other queries as follows.

Create(i): $\mathcal{G}$ maintains an initially empty list $L_{C}$ consisting of tuples of the form $\left(I D_{i}, s_{i}, R_{i}, x_{i}, P_{i}\right)$. $\mathcal{T}$ chooses three random numbers $s_{i}, h_{i}, x_{i} \in Z_{n}^{*}$, computes $\quad R_{i}=s_{i} P-h_{i} P_{\text {pub }}, \quad P_{i}=x_{i} P \quad$ sets $\quad H_{1}\left(I D_{i}, R_{i}\right) \leftarrow h_{i} \quad$ and stores ( $I D_{i}, s_{i}, R_{i}, x_{i}, P_{i}$ ) and ( $I D_{i}, R_{i}, h_{i}$ ) in $L_{C}$ and $L_{H_{1}}$ separately.
$H_{2}\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right): \tau$ maintains an initially empty list $L_{H_{2}}$ with entries of the form ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k$ ). If the tuple is in the list $L_{H_{2}}$, $\tau$ responds with $s k$. Otherwise, $\tau$ responds to these queries in the following way:

- $\tau$ looks the list $L_{S}$ for entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, *\right)$. If $\tau$ finds the entry, he computes

$$
\begin{align*}
& \bar{Z}_{1}=Z_{1}-s_{i}\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right)\right)-s_{j} T_{i}  \tag{20}\\
& \bar{Z}_{2}=Z_{2} \tag{21}
\end{align*}
$$

and

$$
\begin{equation*}
\bar{Z}_{2}=Z_{2}-x_{i}\left(T_{j}+P_{j}\right)-x_{j} T_{i} \tag{21}
\end{equation*}
$$

Then $\tau$ checks whether $Z_{i}$ is correct by checking whether the oracle $\mathcal{O}_{\text {dahp }}$ outputs 1 when the tuple $\left(T_{i}, T_{j}, \bar{Z}_{i}\right)$ is inputted, where $i=1,2,3$. If $Z_{1}, Z_{2}$ and $Z_{3}$ are correct, $\tau$ stores the tuple $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right)$ into $L_{H_{2}}$, where the value sk comes from $L_{S}$. Otherwise, $\mathcal{G}$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk ) into $L_{H_{2}}$.

- Otherwise, $\mathfrak{G}$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk ) into $L_{H_{2}}$.

RevealPartialPrivateKey(i): $\mathcal{G}$ looks up the list $L_{C}$ and returns the corresponding partial private key $s_{i}$ to the adversary $\mathscr{\mathscr { t }} 1$.

RevealEphemeralKey $\left(\Pi_{i, j}^{s}\right): \mathcal{G}$ answers $\mathscr{Z} 1$ 's queries as follows.

- If $\Pi_{i, j}^{s}=\Pi_{I, J}^{s}$ or $\Pi_{i, j}^{s}=\Pi_{J, I}^{T}$, then $\tau$ stops the simulation.

$\operatorname{Send}\left(\prod_{i, j}^{s}, m\right): \mathcal{G}$ maintains an initially empty list $L_{S}$ with entries of the form $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, s k\right)$ and answers $\mathscr{C} 1$ 's queries as follows.
- If $\Pi_{i, j}^{s}=\Pi_{I, J}^{T}, \tau$ returns $T_{i}=U$ to $\mathscr{Z} 1$.
- Otherwise, if $\Pi_{i, j}^{s}=\prod_{I, J}^{T}, ~ 飞$ returns $T_{i}=V$ to $\mathscr{Z} 1$.
- Otherwise, $G$ replies according to the specification of the protocol.

As the attack that adversary $\mathscr{\mathscr { C }} 1$ mounts the forging attack, if $\mathscr{\mathscr { C }} 1$ succeeds, it must have queried oracle $H_{2}$ on the form $Z_{1}=\left(t_{I}+s_{I}\right)\left(T_{J}+R_{J}+H_{1}\left(I D_{J}, R_{J}\right) P_{p u b}\right) \quad, \quad Z_{2}=\left(t_{I}+x_{I}\right)\left(T_{J}+P_{J}\right) \quad$ and $Z_{3}=t_{I} T_{J}$, where $T_{I}=U$ is the outgoing message of Test session by the simulator and $T_{J}=V$ is the incoming message from the adversary $\mathscr{\mathscr { C }} 1$. To solve $c d h(U, V)$, for all entries in $L_{H_{2}}, \quad \tau$ randomly chooses one entry with the probability $\frac{1}{n_{2}}$ and returns $Z_{3}$ as the solution to $\operatorname{cdh}(U, V)$.

The advantage of $\tau$ solving GDH problem with the advantage

$$
\begin{equation*}
A d v_{\widetilde{\widetilde{c}}}^{G D H}(k) \geq \frac{1}{n_{0} n_{1}^{2} n_{2}} A d v_{\tilde{\tilde{x}} 1}(k) \tag{22}
\end{equation*}
$$

Then $A d v_{\bar{G}}^{G D H}(k)$ is non-negligible since we assume that $A d v_{\tilde{z} 11}(k)$ is nonnegligible. This contradicts the GDH assumption.

We could conclude that the advantage of a type 1 adversary against our protocol is negligible if the GCDH problem is intractable.

Lemma 2. Assuming that the GDH problem is intractable, the advantage of a type 2 adversary against our protocol is negligible.

Proof. Suppose that there is a type 2 adversary $\mathscr{\mathscr { t }} 2$ who can win the game defined in subsection 2.3 with a non-negligible advantage $\operatorname{Adv} v_{\mathfrak{z} 2}(k)$ in polynomial-time $t$. Then, we will show how to use the ability of $\mathscr{\mathscr { t }} 2$ to construct an algorithm $\tau$ to solve the GDH problem.

Let $n_{0}$ be the maximum number of sessions that any one party may have. Assume that the adversary $\mathscr{\mathscr { C }} 2$ activates at most $n_{1}$ distinctive honest parties. Assume that the adversary $\mathscr{\mathscr { t }} 2$ activates at most $n_{2}$ distinctive hash queries. Assume also that $A d v_{\tilde{\mathscr{t}} 2}(k)$ is non-negligible. Before the game starts, $\mathcal{G}$ tries to guess the test session and the strategy that the adversary $\mathscr{C} 2$ will adopt. $\mathcal{G}$ randomly selects two indexes $I, J \in\left\{1, \cdots, n_{1}\right\}: I \neq J$, which represent the $I$ th and the $J$ th distinct honest party that the adversary initially chooses. Also, $\mathcal{G}$ chooses $S \in\left\{1, \cdots, n_{0}\right\}$ and determines the Test session $\Pi_{I, J}^{S}$, which is correct with probability larger than $\frac{1}{n_{0} n_{1}^{2}}$. Let $\Pi_{J, I}^{T}$ be the matching session of $\Pi_{I, J}^{s}$. Since $H_{1}$ and $H_{2}$ are modeled as random oracles, after the adversary issues the test query, it has only three possible ways to distinguish the tested session key from a random string:

CASE 1: Forging attack: Assume that $\prod_{I, J}^{S}$ is the test session. At some point in its run, the adversary $\mathscr{\mathscr { t }} 1$ queries $H_{2}$ on the value $\left(I D_{I}, I D_{J}, T_{I}, T_{J}, K_{I J}^{1}, K_{I J}^{2}, K_{I J}^{3}\right)$ in the test session owned by $I$ communicating with $J$. Clearly, in this case $\mathscr{C} 2$ computes the values $K_{I J}^{1}$, $K_{I J}^{2}$ and $K_{I J}^{3}$ itself.

CASE 2: Guessing attack: $\mathscr{\mathscr { C } 2}$ correctly guesses the session key.
CASE 3: Key-replication attack: The adversary $\mathscr{\mathscr { t }} 2$ forces a nonmatching session to have the same session key with the test session. In this case, the adversary $\mathscr{\mathscr { t }} 2$ can simply learn the session key by querying the nonmatching session.

Through the same analysis, we know the success probability of Keyreplication attack and Guessing attack is also negligible. Thus Guessing attack and Key-replication attack can be ruled out. As the attack that the adversary
$\mathscr{\mathscr { t }} 2$ mounts is Forging attack, $\mathscr{\mathscr { A } 2}$ can not get an advantage in winning the game against the protocol unless it queries the $\mathrm{H}_{2}$ oracle on the session key.

In the following, a challenger $\mathcal{G}$ is interested to use the adversary $\mathscr{\mathscr { t }} 2$ to turn $\mathscr{\mathscr { t }} 2$ 's advantage in distinguishing the tested session key from a random string into an advantage in solving the GDH problem. The following two subcases should be considered.

CASE 1.1: No honest party owns a matching session to the Test session.
CASE 1.2: The Test session has a matching session owned by another honest party.

## > The analysis of CASE 1.1:

Since $\mathscr{\mathscr { Z } 2}$ is strong type 2 adversary, then he can get any users' partial private key since he is a malicious KGC. According to Definition 2, $\mathcal{G}$ has the following two choices for $\mathscr{\mathscr { t }} 2$ 's strategy:

CASE 1.1.1: At some point, the secret value of party $I$ has been revealed by the adversary $\mathscr{\mathscr { t }} 2$. According to Definition 2, $\mathscr{\mathscr { t }} 2$ is not permitted to reveal the ephemeral private key of the Test session.

CASE 1.1.2: The secret value of party $I$ has never been revealed by the adversary $\mathscr{\mathscr { L }} 2$. According to Definition 2, $\mathscr{\mathscr { C }} 2$ may reveal the ephemeral private key of the Test session.

## CASE 1.1.1:

Let $A d v_{\widetilde{G}}^{G D H}(k)$ be the advantage that the challenger $\tau$ gets in solving the GDH problem given the security parameter $k$. Given a GDH problem instance $\left(U=u P, V=v P, \mathcal{O}_{\text {ddhp }}\right)$ and $\mathcal{T}$ 's task is to compute $c d h(U, V)=u v P$, where $\mathcal{O}_{\text {ddhp }}$ is a decision oracle that on input ( $a P, b P, c P$ ), answers 1 if $c d h(a P, b P)=c P$; answers 0 , otherwise. $\tau$ first chooses a random number $x \in Z_{n}^{*}$, sets $x P$ as the system public key $P_{\text {pub }}$, selects the system parameter params $=\left\{F_{p}, E / F_{p}, G, P, P_{p u b}, H_{1}, H_{2}\right\}$, and sends params to $\mathscr{\mathscr { t }} 2$. Then, $\mathcal{G}$ simulates the game outlined in Section 2.3 as follows.

Create(i): $\mathbb{G}$ maintains an initially empty list $L_{C}$ consisting of tuples of the form $\left(I D_{i}, s_{i}, R_{i}, x_{i}, P_{i}\right)$ If $i=J, T$ chooses two random numbers $r_{i} \in Z_{n}^{*}$, computes $R_{i}=r_{i} P, h_{i}=H_{1}\left(I D_{i}, R_{i}\right), s_{i}=r_{i}+h_{i} x, P_{i}=U$ and stores $\left(I D_{i}, s_{i}, R_{i}, \perp, P_{i}\right)$ in $L_{C}$. Otherwise, $\tau$ chooses two random numbers $r_{i}, x_{i} \in Z_{n}^{*}$,
computes $R_{i}=r_{i} P, \quad h_{i}=H_{1}\left(I D_{i}, R_{i}\right), \quad s_{i}=r_{i}+h_{i} x, \quad P_{i}=x_{i} P$ and stores $\left(I D_{i}, s_{i}, R_{i}, x_{i}, P_{i}\right)$ in $L_{C}$.
$H_{1}\left(I D_{i}, R_{i}\right): \tau$ maintains an initially empty list $L_{H_{1}}$ which contains tuples of the form $\left(I D_{i}, R_{i}, h_{i}\right)$. If $\left(I D_{i}, R_{i}\right)$ is on the list $L_{H_{1}}, G$ returns $h_{i}$. Otherwise, $\tau$ chooses a random number $h_{i}$, stores $\left(I D_{i}, R_{i}, h_{i}\right)$ in $L_{H_{1}}$ and returns $h_{i}$.
$H_{2}\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right): \tau$ maintains an initially empty list $L_{H_{2}}$ with entries of the form ( $\left.I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right)$. If the tuple is in the list $L_{H_{2}}, G$ responds with $s k$. Otherwise, $\sigma$ responds to these queries in the following way:

- If $I D_{i}=I D_{J}$,
- $G$ looks the list $L_{S}$ for entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, *\right)$. If $\tau$ finds the entry, he computes $\bar{Z}_{2}=Z_{2}-t_{i}\left(T_{j}+P_{j}\right)-x_{j} P_{i}$.
- Then $\tau$ checks whether $Z_{2}$ is correct by checking whether the oracle $\mathcal{O}_{\text {ddhp }}$ outputs 1 when the tuple $\left(P_{i}, T_{j}, \bar{Z}_{2}\right)$ is inputted. $\mathcal{G}$ also checks whether $Z_{1}$ and $Z_{3}$ are equal by checking whether the equations $Z_{1}=\left(t_{i}+s_{i}\right)\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right)\right) \quad$ and $\quad Z_{3}=t_{i} T_{j}$ hold separately. If $Z_{1}, Z_{2}$ and $Z_{3}$ are correct, $G$ stores the tuple $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k\right)$ into $L_{H_{2}}$, where the value $s k$ comes from $L_{S}$. Otherwise, $\tau$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$,sk) into $L_{H_{2}}$.
- Otherwise,
- $\mathcal{G}$ looks the list $L_{S}$ for entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, *\right)$. If $\tau$ finds the entry, he stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, s k$ ) into $L_{H_{2}}$, where the value $s k$ comes from $L_{S}$.
- Otherwise, $\tau$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk $)$ into $L_{H_{2}}$.

RevealPartialPrivateKey(i): $\tau$ looks up the list $L_{E}$ and returns the corresponding partial private key $s_{i}$ to the adversary $\mathscr{\mathscr { t }} 2$.

RevealSecretValue(i): 飞 answers $\mathscr{\mathscr { Z }} 2$ 's queries as follows.

- If $I D_{i}=I D_{J}$, then $\tau$ stops the simulation.
- Otherwise, $\tau$ looks up the table $L_{C}$ for entry ( $I D_{i},{ }^{*}, *,{ }^{*}, *$ ) and returns $x_{i}$.

RevealEphemeralKey $\left(\Pi_{i, j}^{t}\right): \mathcal{T}$ answers $\check{\mathscr{t}} 2$ 's queries as follows.

- If $\prod_{i, j}^{s}=\prod_{I, J}^{s}$, then $\tau$ stops the simulation.
- Otherwise, $\mathbb{G}$ returns the stored ephemeral private key to $\mathscr{\mathscr { Z }} 2$.

RevealMasterKey: $\mathcal{G}$ returns the master key $x$ to $\mathscr{C} 2$.
RevealSessionKey $\left(\prod_{i, j}^{t}\right): \tau$ answers $\check{\mathscr{C}} 2$ 's queries as follows.

- If $\Pi_{i, j}^{s}=\prod_{I, J}^{S}$ or $\prod_{i, j}^{s}=\prod_{I, J}^{T}$, then $\sigma$ stops the simulation.
- Otherwise, if $\mathcal{G}$ returns the session key $s k$ to $\mathscr{\mathscr { C }} 2$.
$\operatorname{Send}\left(\prod_{i, j}^{s}, m\right): \mathcal{T}$ maintains an initially empty list $L_{S}$ with entries of the form $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, s k\right)$ and answers $\mathscr{\mathscr { C }} 2$ 's queries as follows.
- If $\Pi_{i, j}^{s}=\Pi_{I, J}^{S}$, then $\mathcal{G}$ returns $T_{i}=V$ to $\mathscr{C} 2$.
- Otherwise, if $I D_{i}=I D_{J}$, he generates a random $t_{i} \in Z_{n}$, computes $\bar{Z}_{2}=Z_{2}-t_{i}\left(T_{j}+P_{j}\right)-x_{j} P_{i}$. Then $\tau$ checks whether $Z_{2}$ is correct by checking whether the oracle $\mathcal{O}_{\text {ddhp }}$ outputs 1 when the tuple ( $P_{i}, T_{j}, \bar{Z}_{2}$ ) is inputted. T also checks whether $Z_{1}$ and $Z_{3}$ are equal by checking whether the equations $Z_{1}=\left(t_{i}+s_{i}\right)\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right)\right)$ and $Z_{3}=t_{i} T_{j}$ hold separately. If $Z_{1}, Z_{2}$ and $Z_{3}$ are correct, $\tau$ stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, s k$ ) into $L_{S}$, where the value sk comes from $L_{H_{2}}$. Otherwise, $\mathcal{G}$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $\left.I D_{i}, I D_{j}, T_{i}, T_{j}, s k\right)$ into $L_{S}$.
- Otherwise, $\mathcal{G}$ replies according to the specification of the protocol.
$\operatorname{Test}\left(\prod_{i, j}^{t}\right): \mathcal{T}$ answers $\mathscr{C L} 2$ 's queries as follows.
- If $\prod_{i, j}^{t} \neq \prod_{I, J}^{S}$, then $\tau$ stops the simulation.
- Otherwise, $\tau$ generates a random number $\xi \in\{0,1\}^{k}$ and returns it to $\mathscr{A} 2$.

As the adversary $\mathscr{\mathscr { Z }} 2$ mounts the forging attack, if $\mathscr{\mathscr { t }} 2$ succeeds, it must have queried oracle $H_{2}$ on the form $Z_{1}=\left(t_{I}+s_{I}\right)\left(T_{J}+R_{J}+H_{1}\left(I D_{J}, R_{J}\right) P_{p u b}\right)$, $Z_{2}=\left(t_{I}+x_{I}\right)\left(T_{J}+U\right)$ and $Z_{3}=t_{I} T_{J}$, where $T_{I}=V$ is the outgoing message of Test session by the simulator and $T_{J}$ is the incoming message from the adversary $\mathscr{\mathscr { t }} 2$. To solve $G D H(U, V)$, for all entries in $L_{H_{2}}$, $\tau$ randomly chooses one entry with the probability $\frac{1}{n_{2}}$ and computes

$$
\begin{equation*}
\left.\bar{Z}_{2}=Z_{2}-x_{I}\left(T_{J}+U\right)\right)-Z_{3} \tag{23}
\end{equation*}
$$

It is easy to verify that the equation $\bar{Z}_{2}=c d h(U, V)$ holds. The advantage of $\tau$ solving GDH problem with the advantage

$$
\begin{equation*}
A d v_{\mathrm{F}}^{G D H}(k) \geq \frac{1}{n_{0} n_{1}^{2} n_{2}} A d v_{\tilde{\mathscr{t} 2}}(k) . \tag{24}
\end{equation*}
$$

Then $A d v_{\mathscr{G}}^{G D H}(k)$ is non-negligible since we assume that $A d v_{\tilde{\mathscr{t}} 2}(k)$ is nonnegligible. This contradicts the GDH assumption.

## CASE 1.1.2:

$\tau$ answers $H_{1}\left(I D_{i}, R_{i}\right)$, RevealPartialPrivateKey(i), RevealEphemeralKey $\left(\Pi_{i, j}^{t}\right)$, RevealMasterKey, RevealSessionKey $\left(\Pi_{i, j}^{t}\right)$ and $\operatorname{Test}\left(\prod_{i, j}^{t}\right)$ as he does in CASE 3.1.3 of Lemma 3. He also answers other queries as follows.

Create(i): $\mathcal{T}$ simulates the oracle in the same way as that of CASE 1.1.1 except for $i=I$. If $i=I, \mathcal{G}$ chooses two random numbers $r_{i} \in Z_{n}^{*}$, computes $R_{i}=r_{i} P, \quad h_{i}=H_{1}\left(I D_{i}, R_{i}\right), \quad s_{i}=r_{i}+h_{i} x, \quad P_{i}=V$ and stores $\left(I D_{i}, s_{i}, R_{i}, \perp, P_{i}\right)$ in $L_{C}$. Otherwise, $\mathcal{G}$ chooses two random numbers $r_{i}, x_{i} \in Z_{n}^{*}$, computes $R_{i}=r_{i} P, \quad h_{i}=H_{1}\left(I D_{i}, R_{i}\right), s_{i}=r_{i}+h_{i} x, \quad P_{i}=x_{i} P$ and stores $\left(I D_{i}, s_{i}, R_{i}, x_{i}, P_{i}\right)$ in $L_{C}$.
$H_{2}\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, h\right): \tau$ simulates the oracle in the same way as that of CASE 1.1.1 except for the form ( $I D_{I}, I D_{J}, T_{I}, T_{J}, Z_{1}, Z_{2}, Z_{3}$ ) and ( $I D_{J}, I D_{I}, T_{J}, T_{I}, Z_{1}, Z_{2}, Z_{3}$ ). T responds to these queries in the following way:

- If $\left(I D_{I}, I D_{J}, T_{I}, T_{J}, Z_{1}, Z_{2}, Z_{3}, h\right)$ or ( $\left.I D_{J}, I D_{I}, T_{J}, T_{I}, Z_{1}, Z_{2}, Z_{3}, h\right)$ is in $L_{H_{2}}, \tau$ responds with the stored value $h$.
- Otherwise, $\tau$ looks up the table $L_{S}$ for entry ( $I D_{i}, I D_{j}, T_{i}, T_{j}$, , ). If there is no such entry, $\mathbb{T}$ choose a random number $h \in\{0,1\}^{k}$ and stores the new entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}, h\right)$ in $L_{H_{2}}$. Otherwise, $\mathcal{G}$ compute $\bar{Z}_{2}=Z_{2}-t_{i}\left(T_{j}+P_{j}\right)-t_{j} P_{i}$. Then $\tau$ checks whether $Z_{2}$ is correct by checking whether the oracle $\mathcal{O}_{\text {ddhp }}$ outputs 1 when the tuple ( $P_{i}, P_{j}, \bar{Z}_{1}$ ) is inputted. $\tau$ also checks whether $Z_{1}$ and $Z_{3}$ are equal by checking if the equations $Z_{1}=\left(t_{i}+s_{i}\right)\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right) P_{p u b}\right)$ and $Z_{3}=t_{i} T_{j}$ hold separately. If $Z_{1}, Z_{2}$ and $Z_{3}$ are correct, $G$ stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$, sk) into $L_{H_{2}}$, where the value sk comes from $L_{s}$. Otherwise, $\mathcal{G}$ chooses a random number $s k \in\{0,1\}^{k}$ and stores the tuple ( $I D_{i}, I D_{j}, T_{i}, T_{j}, Z_{1}, Z_{2}, Z_{3}$,sk) into $L_{H_{2}}$.

RevealSecretValue(i):: $\mathbb{T}$ simulates the oracle in the same way as that of CASE 1.1.1 except for $i=I$. If $i=I, \quad \tau$ stops the simulation.
$\operatorname{Send}\left(\prod_{i, j}^{s}, m\right): \tau$ simulates the oracle in the same way as that of CASE 1.1 except for the following queries:

- If $\Pi_{i, j}^{s}=\Pi_{I, J}^{s}, G$ chooses $t_{i} \in Z_{n}$ and returns $T_{i}=t_{i} P$ to $\mathscr{A} 1$.
- If $i=I$ and $j=J$ (the case that $i=J$ and $j=I$ could be deal with similarly).
- $\mathcal{G}$ chooses $t_{i} \in Z_{n}$ and returns $T_{i}=t_{i} P$ to $\mathscr{C} 1$.

T looks up the list $L_{H_{2}}$ for entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j},{ }^{*},{ }^{*},{ }^{*},{ }^{*}\right)$ (If $\prod_{i, j}^{s}$ is responder session, $\tau$ will look up for $\left(I D_{j}, I D_{i}, T_{j}, T_{i},{ }^{*},{ }^{*},{ }^{*}, *\right)$ ). If there is no such entry, $\tau$ choose a random number $s k \in\{0,1\}^{k}$ and stores the new entry $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, s k\right)$ in $L_{s}$. Otherwise, $G$ computes $\bar{Z}_{2}=Z_{2}-t_{i}\left(T_{j}+P_{j}\right)-t_{j} P_{i}$. Then $\tau$ checks whether $Z_{2}$ is correct by checking whether the oracle $\mathcal{O}_{\text {ddhp }}$ outputs 1 when the tuple $\left(P_{i}, P_{j}, \bar{Z}_{1}\right)$ is inputted. $G$ also checks whether $Z_{2}$ and $Z_{3}$ are equal by checking if
the equations $Z_{1}=\left(t_{i}+s_{i}\right)\left(T_{j}+R_{j}+H_{1}\left(I D_{j}, R_{j}\right) P_{p u b}\right)$ and $Z_{3}=t_{i} T_{j}$ hold separately. If all of the equations are equal, $\tau$ stores $\left(I D_{i}, I D_{j}, T_{i}, T_{j}, h\right)$ into $L_{S}$, where $h$ comes from $L_{H_{2}}$. Otherwise, $\mathcal{G}$ chooses a random number sk and stores ( $I D_{i}, I D_{j}, T_{i}, T_{j}, s k$ ) into $L_{s}$.

As the adversary $\mathscr{\mathscr { t }} 2$ mounts the forging attack, if $\mathscr{\mathscr { t }} 2$ succeeds, it must have queried oracle $H_{2}$ on the form $Z_{1}=\left(t_{I}+s_{I}\right)\left(T_{J}+R_{J}+H_{1}\left(I D_{J}, R_{J}\right) P_{p u b}\right)$, $Z_{2}=\left(t_{I}+x_{I}\right)\left(T_{J}+U\right)$ and $Z_{3}=t_{I} T_{J}$, where $P_{I}=U, P_{J}=V$ and $T_{J}$ is the incoming message from the adversary $\mathscr{\mathscr { t }} 2$. To solve $G D H(U, V)$, for all entries in $L_{H_{2}}, \tau$ randomly chooses one entry with the probability $\frac{1}{n_{2}}$ and proceeds with following steps:
$G$ computes

$$
\begin{equation*}
\bar{Z}_{2}=Z_{2}-t_{I}\left(T_{J}+U\right)-t_{J} V=c d h(U, V) \tag{25}
\end{equation*}
$$

The advantage of $\tau$ solving GDH problem with the advantage

$$
A d v_{\bar{\tau}}^{G D H}(k) \geq \frac{1}{n_{0} n_{1}^{2} n_{2}} A d v_{\tilde{\mathscr{t} 2}}(k) .
$$

Then $\operatorname{Adv} v_{\overleftarrow{G}}^{G D H}(k)$ is non-negligible since we assume that $A d v_{\tilde{z} t 2}(k)$ is nonnegligible. This contradicts the GDH assumption.

## > The analysis of CASE 1.2:

In this case, the Test session $\Pi_{I, J}^{S}$ has a matching session owned by another honest party $J$. According to Definition 1, the adversary $\mathscr{\mathscr { C }} 1$ has four ways to mount the attacks.

CASE 1.2.1. The adversary $\mathscr{\mathscr { C } 1} 1$ makes ephemeral key query to both the Test session and the matching session of the Test session (The adversary does not reveal their corresponding partial private key). In this case, the proof is identical to that of CASE 1.1.2. To save space, we omit the details.

CASE 1.2.2. The adversary $\mathscr{\mathscr { C }} 1$ makes queries to the partial private key of the owner of Test session and its peer's ephemeral private key. In this case, the proof is identical to that of CASE 1.1.1. To save space, we omit the details.

CASE 1.2.3. The adversary $\mathscr{\mathscr { C }} 1$ makes queries to the ephemeral private key of the owner of Test session and its peer's partial private key. In this case, the proof is identical to that of CASE 1.1.1. To save space, we omit the details.

CASE 1.2.4. The adversary $\mathscr{\mathscr { t }} 1$ learns the partial private key of both the owner of Test session and its peer. (The adversary does not reveal their corresponding ephemeral private key). In this case, the proof is identical to that of CASE 1.2.4 of the above lemma. To save space, we omit the details.

We could conclude that the advantage of a type 2 adversary against our protocol is negligible if the GCDH problem is intractable.

From the above three lemmas, we can get the following theorem.
Theorem 1. Our protocol is a secure CLAKA protocol in the eCK model under the GDH assumption.

## 5. Comparison with previous protocols

Let mBR and eCK denote the modified Bellare-Rogaway model [17] and the extended Canetti-Krawczyk (eCK) model [18] separately. For the convenience of evaluating the computational cost, we define some notations as follows.

- $T_{\text {mul }}$ : The time of executing a scalar multiplication operation of point.
- $T_{\text {add }}$ : The time of executing an addition operation of point.
- $T_{i n v}$ : The time of executing a modular invasion operation.
- $\quad T_{h}$ : The time of executing a one-way hash function.

We will compare the efficiency of our protocol with five CLAKA protocols without pairings, i.e. Geng et al.'s protocol [12], Hou et al.'s protocol [13], Yang et al.'s protocol[14], and He et al.'s protocols[15,16]. Table 1 shows the comparison between pairing-free CLAKA protocols in terms of efficiency, security model and underlying hardness assumptions.

Since the scalar multiplication operation of point is more complicated than the addition operation of points, modular invasion operation and the hash function operation, then our protocol has better performance than Geng et al.'s protocol [12], Hou et al.'s protocol [13] and He et al's protocol[15]. Moreover, Geng et al.'s protocol [12], Hou et al.'s protocol [13] and He et al's protocol[15] are not secure against type 1 adversary. Then our protocol has advantage in both the performance and the security over Geng et al.'s protocol [12], Hou et al.'s protocol [13] and He et al's protocol [15]. It is well known that the eCK model is much superior to the mBR model. Then Yang et al.'s protocol [15] and our protocol has advantage in security to He et al.'s protocol [16]. At the same time,
our protocol also has better performance than He et al.'s protocol [16]. Yang et al.'s proposed the first pairing-free CLAKA protocol, which is provably secure in the eCK model. However, in Yang et al.'s protocol, the user has to verify the validity of public keys. This does not only increase the burden of the user, but also reverse the thought of CLPKC. From Table 1, we know our protocol has much better performance than Yang et al.'s protocol [15]. We conclude that our protocol is more suitable for practical applications.

Table 1: Comparisons among different protocols

|  | Computational <br> cost | Security <br> model | Assumption | Message <br> exchange |
| :--- | :---: | :---: | :---: | :---: |
| Geng et al.'s <br> protocol [12] | $7 T_{\text {mul }}+2 T_{h}$ | mBR | GDH | 2 |
| Hou et al.'s <br> protocol [13] | $6 T_{\text {mul }}+2 T_{h}$ | mBR | GDH | 2 |
| Yang et al.'s <br> protocol [14] | $9 T_{\text {mul }}+2 T_{h}$ | eCK | GDH | 2 |
| He et al's <br> protocol[15] | $5 T_{\text {mul }}+3 T_{\text {add }}$ <br> $+T_{\text {inv }}+2 T_{h}$ | mBR | GDH | 3 |
| He et al's <br> protocol[16] | $5 T_{\text {mul }}+4 T_{\text {add }}$ <br> $+2 T_{h}$ | mBR | GDH | 2 |
| Our protocol | $5 T_{\text {mul }}+3 T_{\text {add }}$ <br> $+2 T_{h}$ | eCK | GDH | 2 |

## 6. Conclusion

The certificateless public key cryptography is receiving significant attention because it is a new paradigm that simplifies the public key cryptography. Recently, several pairing-free CLAKA have been proposed. In this paper, we proposed a more efficient CLAKA protocol without pairings and proved its security in the eCK model under the GDH assumption. The proposed protocol has the best performance among the related protocols.
