**Abstract.** We relate certain models of Axiomatic Domain Theory (ADT) and Synthetic Domain Theory (SDT). On the one hand, we introduce a class of non-elementary models of SDT and show that the domains in them yield models of ADT. On the other hand, for each model of ADT in a wide class we construct a model of SDT such that the domains in it provide a model of ADT which conservatively extends the original model.

## Introduction

The aim of *Axiomatic Domain Theory* (ADT) is to axiomatise the structure needed on a category so that its objects can be considered to be domains (see [11, § Axiomatic Domain Theory]).

Models of axiomatic domain theory are given with respect to an *enrichment base* provided by a model of intuitionistic linear type theory [2, 3]. These enrichment structures consist of a monoidal adjunction  $\mathcal{C} \overset{\rightarrow}{\perp} \mathcal{D}$  between a cartesian closed category  $\mathcal{C}$  and a symmetric monoidal closed category with finite products  $\mathcal{D}$ , as well as with an  $\omega$ -inductive fixed-point object (Definition 1.11 (2)). Roughly speaking, an  $\omega$ -inductive fixed-point object is an initial algebra (for the endofunctor underlying the monad induced by the adjunction) arising as the colimit of a standard  $\omega$ -chain, equipped with a global element invariant under successor. With respect to such a structure, a model of axiomatic domain theory is a  $\mathcal{D}$ -category which is closed under suitable  $\mathcal{C}$ -enriched type constructors (as, for example, products, higher types, and sums) and is  $\mathcal{C}$ -algebraically compact. The rôle of algebraic compactness is to provide a universal method of solving recursive type equations [15]; in this context algebraic compactness is guaranteed by the usual completeness conditions on the model [28].

The canonical example of an enrichment base is obtained by taking:

- $\mathcal{C} = \mathbf{Cpo}$ , the category of small cpos — $\omega$ -complete partial orders— and continuous functions;

---

\* Research supported by Typed Lambda Calculus network ERBCHRXCT920046.

\*\* Research supported by an EPSRC Senior Fellowship.

- $\mathcal{D} = \mathbf{Cppo}_{\perp}$ , the category of small cpos — $\omega$ -complete pointed partial orders— and strict continuous functions, with the symmetric monoidal closed structure given by the Sierpinski space, smash products, and strict exponentials; and
- the adjunction  $\mathbf{Cpo} \xrightarrow{\perp} \mathbf{Cppo}_{\perp}$  with left adjoint given by *lifting*.

In this example, the inductive fixed-point object is the ordinal  $\omega + 1$  equipped with its limit point  $\omega$ .

A typical model, with respect to the above enrichment base, is  $\mathbf{pCpo}$  (the category of small cpos and partial continuous functions [27]); it has partial products, Kleisli (or partial) exponentials and finite coproducts (all yielding  $\mathbf{Cpo}$ -functors), and it is  $\mathbf{Cpo}$ -algebraically compact [8]. This example is representative of the class of models that we consider in this paper in that the lifting monad  $\mathbb{L}$  on  $\mathbf{Cpo}$  allows us to recover the other data. Indeed, we have that  $\mathbf{Cppo}_{\perp} \cong \mathbf{Cpo}^{\mathbb{L}}$  (the category of Eilenberg-Moore algebras for  $\mathbb{L}$ ) and that  $\mathbf{pCpo} \cong \mathbf{Cpo}_{\mathbb{L}}$  (the Kleisli category for  $\mathbb{L}$ ). Moreover, as is well-known, the smash product is characterised by the property that for cpos  $P$  and  $Q$ , the canonical bistrict map  $P \times Q \rightarrow P \otimes Q$  is universal among bistrict maps.

The models that we consider generalise the above example and are those given by a category  $\mathcal{C}$  equipped with an initial object, a cartesian closed structure, a lifting monad  $\mathbb{L}$ , and an inductive fixed-point object such that  $\mathcal{C}^{\mathbb{L}}$  has tensor products and linear exponentials (respectively axiomatising smash products and strict exponentials) and  $\mathcal{C}_{\mathbb{L}}$  is  $\mathcal{C}$ -algebraically compact. It follows that  $\mathcal{C}^{\mathbb{L}}$  is cartesian and that  $\mathcal{C}_{\mathbb{L}}$  has partial products and Kleisli exponentials yielding  $\mathcal{C}$ -functors. (In this paper we do not assume our models to have binary coproducts; however it seems possible to extend our analysis to obtain analogous results for this situation.)

The slogan of *Synthetic Domain Theory (SDT)* is that domains are sets and all functions between them are continuous (see [11, § Synthetic Domain Theory]). Thus, within a suitable universe of sets, generally taken to be a topos, one wishes to identify the sets which behave like domains. In this paper, following a suggestion of Hyland, we relate the axiomatic and synthetic viewpoints. In fact, we give a non-elementary version of SDT yielding a category of domains that complies with the axiomatic requirements (Theorem 3.1). And, as a main result (Theorem 3.4), for every small (Kleisli) ADT model (Definition 1.12 (2)) we construct a (Grothendieck) model of our SDT (Definition 2.13) whose domains yield a (Kleisli) ADT model conservatively extending the original model.

## 1 Axiomatic domain theory

We introduce the concepts and results of ADT needed in the rest of the paper. In Subsections 1.1 and 1.2 we recall the notions of lifting monad, tensor products and linear exponentials, and study them in presheaf toposes. In Subsections 1.3 and 1.4, we further recall the notions of partial products and Kleisli exponentials, and algebraic compactness, which respectively permit the interpretation of

simple types (in Kleisli categories) and of recursive types. Finally, in Section 1.5 we define the class of ADT models that we will be interested in.

### 1.1 Lifting

We present an axiomatisation of *lifting* in terms of *dominances* [30] which is by now traditional; its connection with *partiality* is discussed briefly. (For details consult [8]).

**Definition 1.1. (Dominance [30])** Let  $\mathcal{C}$  be a category with a terminal object  $\mathbf{1}$ . An object  $\Sigma$  equipped with a subobject  $\top : \mathbf{1} \hookrightarrow \Sigma$  such that pullbacks of  $\top$  (henceforth called  $\top$ -subobjects) always exist is called a  $\top$ -*subobject classifier* if every  $\top$ -subobject  $U \hookrightarrow A$  appears in a pullback

$$\begin{array}{ccc} U & \longrightarrow & \mathbf{1} \\ \downarrow & \lrcorner & \downarrow \top \\ A & \longrightarrow & \Sigma \end{array}$$

for a unique *characteristic map*  $A \rightarrow \Sigma$ .

A  $\top$ -subobject classifier is called a *dominance* if  $\top^* : \mathcal{C}/\Sigma \rightarrow \mathcal{C}$  has a right adjoint, and  $\top$ -subobjects are closed under composition. (For details consult [30, 17]).  $\square$

*Remark.* In the context of SDT, the notion of dominance is only defined by the second requirement, as the first requirement generally holds in the universes of sets considered (e.g. locally cartesian closed categories with finite limits, such as toposes or quasitoposes).

*Convention.* We will use  $\hookrightarrow$  to indicate  $\top$ -subobjects.

A dominance  $\top : \mathbf{1} \hookrightarrow \Sigma$  in a category  $\mathcal{C}$  allows one to consider partial maps with domain of definition a  $\top$ -subobject and action a  $\mathcal{C}$ -map. To this end, one defines a  $\top$ -*partial map*  $A \rightarrow B$  as (a representative of) an equivalence class of diagrams of the form  $A \hookrightarrow U \rightarrow B$  with  $U \hookrightarrow A$  a  $\top$ -subobject where  $(A \hookrightarrow U \rightarrow B) \equiv (A \hookrightarrow V \rightarrow B)$  if for some  $U \cong V$ ,  $(A \hookrightarrow U) = (A \hookrightarrow V \cong U)$  and  $(U \rightarrow B) = (U \cong V \rightarrow B)$ . Moreover, for a well-powered  $\mathcal{C}$ ,  $\top$ -partial maps form a category with the same objects as  $\mathcal{C}$ , composition given by setting  $[B \hookrightarrow V \rightarrow C] \circ [A \hookrightarrow U \xrightarrow{f} B] \stackrel{\text{def}}{=} [A \hookrightarrow U \hookrightarrow f^{-1}(V) \rightarrow V \rightarrow C]$ , and identities given by  $[A \hookrightarrow A \rightarrow A]$ .

In the context of a category with a dominance  $\top : \mathbf{1} \hookrightarrow \Sigma$ , writing  $\Pi_{\top}$  for the right adjoint to  $\top^*$ , we have, for every  $B \in |\mathcal{C}|$ , that  $(\Pi_{\top} B)^*(\top) \cong B$ ; hence

obtaining a pullback diagram

$$\begin{array}{ccc}
 B & \longrightarrow & \mathbf{1} \\
 \eta_B \downarrow \lrcorner & & \downarrow \lrcorner \mathbb{T} \\
 LB & \xrightarrow{\Pi_{\mathbb{T}} B} & \Sigma
 \end{array} . \tag{1}$$

Moreover, the  $\mathbb{T}$ -subobject  $\eta_B : B \hookrightarrow LB$  in (1) is a *classifier of  $\mathbb{T}$ -partial maps* with target  $B$ , in that every  $\mathbb{T}$ -partial map  $[A \hookrightarrow U \rightarrow B]$  appears in a pullback

$$\begin{array}{ccc}
 U & \longrightarrow & B \\
 \downarrow \lrcorner & & \downarrow \lrcorner \eta_B \\
 A & \longrightarrow & LB
 \end{array}$$

for a unique *characteristic map*  $A \rightarrow LB$ .

The following is well-known (see e.g. [17, 25, 8]):

**Proposition 1.2.** *In a cartesian category, dominances induce commutative monads.*  $\square$

*Remark.* For the notion of *commutative monad* see [20, 24]. The underlying endofunctor of the monad induced by a dominance  $\mathbb{T} : \mathbf{1} \hookrightarrow \Sigma$  is given by the composite  $\mathcal{C} \xrightarrow{\Pi_{\mathbb{T}}} \mathcal{C}/\Sigma \rightarrow \mathcal{C}$  where  $\mathcal{C}/\Sigma \rightarrow \mathcal{C}$  is the *domain* functor.

*Convention.* We refer to the monad induced by a dominance as the *lifting monad* and denote it  $\mathbb{L}$ ; its underlying endofunctor and unit are respectively denoted  $L$  and  $\eta$  (this is consistent with the notation already used in (1)).

Further, the Kleisli category for a monad  $\mathbb{T}$  on a category  $\mathcal{C}$  is denoted  $\mathcal{C}_{\mathbb{T}}$ .

Given a dominance  $\mathbb{T} : \mathbf{1} \hookrightarrow \Sigma$  on a category  $\mathcal{C}$ , the Kleisli category  $\mathcal{C}_{\mathbb{L}}$  is isomorphic to the category of  $\mathbb{T}$ -partial maps as described above; and hence from now on we will feel free to regard a morphism  $A \rightarrow B$  in  $\mathcal{C}_{\mathbb{L}}$  either as a morphism  $A \rightarrow LB$  in  $\mathcal{C}$  or as a  $\mathbb{T}$ -partial map  $A \rightarrow B$ .

**Proposition 1.3.** *In a category with a strict initial object  $0$  and a dominance  $\mathbb{T} : \mathbf{1} \hookrightarrow \Sigma$  for which the map  $0 \rightarrow \mathbf{1}$  is a  $\mathbb{T}$ -subobject,  $L0 \cong \mathbf{1}$ .*  $\square$

**Lifting in presheaf toposes.** We proceed to study lifting in presheaf toposes. Such a study was started by Rosolini in his thesis [30]; here we build on top of his work.

*Convention.* For a small category  $\mathcal{A}$ , we write  $\widehat{\mathcal{A}}$  for the presheaf topos  $[\mathcal{A}^{\text{op}}, \mathbf{Set}]$  where, as usual,  $\mathbf{Set}$  denotes the category of small sets and functions. Moreover, we always identify  $\mathcal{A}$  with its image under the Yoneda embedding  $\mathcal{A} \hookrightarrow \widehat{\mathcal{A}}$ . For a small category  $\mathcal{A}$  with an initial object, we write  $\widetilde{\mathcal{A}}$  for the sheaf topos obtained by declaring that the empty cover covers the initial object; when the initial object is *strict*,  $\widetilde{\mathcal{A}}$  is simply the full subcategory of  $\widehat{\mathcal{A}}$  consisting of all those presheaves  $P$  for which  $P(0) \cong 1$ .

**Theorem 1.4.** ([30]) *Let  $\mathcal{A}$  be a small category and let  $\mathcal{M}$  be a class of admissible monos (i.e. closed under isomorphisms, composition and pullbacks along arbitrary maps). In  $\widehat{\mathcal{A}}$ ,  $\top : 1 \hookrightarrow \Sigma$  defined by  $\Sigma(A) \stackrel{\text{def}}{=} \{[m] \mid m : U \hookrightarrow A \text{ in } \mathcal{M}\}$  with action given by pullback and  $\top_A \stackrel{\text{def}}{=} [\text{id}_A]$ , is a dominance. Moreover,  $O \hookrightarrow P$  is a  $\top$ -subobject in  $\widehat{\mathcal{A}}$  if and only if for all  $A \rightarrow P$  with  $A \in |\mathcal{A}|$  there exists  $U \hookrightarrow A$  in  $\mathcal{M}$  such that*

$$\begin{array}{ccc} U & \longrightarrow & O \\ \downarrow & \lrcorner & \downarrow \\ A & \longrightarrow & P \end{array} .$$

□

**Corollary 1.5.** *Let  $\mathcal{A}$  be a small category with a strict initial object  $0$  and a dominance  $\top : 1 \hookrightarrow \Sigma$  for which the map  $0 \rightarrow 1$  is a  $\top$ -subobject.*

1. *The Yoneda embedding  $\mathcal{A} \hookrightarrow \widehat{\mathcal{A}}$  cuts down to an embedding  $\mathcal{A} \hookrightarrow \widetilde{\mathcal{A}}$ .*
2. *The Yoneda embedding  $\mathcal{A} \hookrightarrow \widetilde{\mathcal{A}}$  preserves the initial object and the dominance (i.e. in  $\widetilde{\mathcal{A}}$ ,  $0$  is initial and  $\top : 1 \hookrightarrow \Sigma$  is a dominance). Moreover, the diagram*

$$\begin{array}{ccccc} \mathcal{A} & \hookrightarrow & \widetilde{\mathcal{A}} & \hookrightarrow & \widehat{\mathcal{A}} \\ L \downarrow & & \downarrow L & & \downarrow L \\ \mathcal{A} & \hookrightarrow & \widetilde{\mathcal{A}} & \hookrightarrow & \widehat{\mathcal{A}} \end{array}$$

*commutes up to isomorphism.*

*Proof.* (1) Because  $0$  is initial in  $\mathcal{A}$ .

(2) The first part follows from Theorem 1.4 using that the  $\top$ -subobjects of a sheaf in  $\widetilde{\mathcal{A}}$  are exactly the  $\top$ -subobjects in  $\widehat{\mathcal{A}}$ . The second part follows from:

**Proposition 1.6.** ([32]) *Let  $\mathcal{S}$  be a topos equipped with a dominance  $\top : 1 \hookrightarrow \Sigma$ . For every topology  $j$  in  $\mathcal{S}$ , if  $\Sigma$  is a  $j$ -sheaf then the lifting in  $\mathcal{S}$  preserves the property of being a  $j$ -sheaf.* □

□

In the situation of the above corollary, the following result provides a description of lifting which is useful for determining its preservation properties with respect to colimits.

**Theorem 1.7.** Let  $\mathcal{A}$  be a small category with a strict initial object  $0$  and a dominance  $\top : 1 \hookrightarrow \Sigma$  for which the map  $0 \rightarrow 1$  is a  $\top$ -subobject.

1. Let  $L^* : \widehat{\mathcal{A}} \rightarrow \widehat{\mathcal{A}} : P \mapsto P \circ L^{\text{op}}$ . For  $L_! : \widehat{\mathcal{A}} \xrightarrow{\perp} \widehat{\mathcal{A}} : L^*$ , the diagram

$$\begin{array}{ccc} \widetilde{\mathcal{A}} & \hookrightarrow & \widehat{\mathcal{A}} \\ L \downarrow & & \downarrow L_! \\ \widetilde{\mathcal{A}} & \hookrightarrow & \widehat{\mathcal{A}} \end{array}$$

commutes up to isomorphism.

2.  $L : \widetilde{\mathcal{A}} \rightarrow \widehat{\mathcal{A}}$  preserves non-empty connected colimits.

*Proof.* (1) For  $P \in |\widehat{\mathcal{A}}|$ ,  $L_!P$  can be explicitly described as the  $P$ -valued partial maps with domain of definition a  $\top$ -subobject in  $\mathcal{A}$ . Formally, we have

- For  $A \in |\mathcal{A}|$ ,  $L_!PA = \{[A \hookrightarrow U \rightarrow P] \mid U \hookrightarrow A \text{ in } \mathcal{A}, U \rightarrow P \text{ in } \widehat{\mathcal{A}}\}$  where  $(A \hookrightarrow U \rightarrow P) \equiv (A \hookrightarrow V \rightarrow P)$  iff there exists  $U \cong V$  such that  $(U \hookrightarrow A) = (U \cong V \hookrightarrow A)$  and  $(U \rightarrow P) = (U \cong V \rightarrow P)$ .
- For  $A \rightarrow B$  in  $\mathcal{A}$ ,  $L_!P(A \rightarrow B)[B \hookrightarrow V \rightarrow P] = [A \hookrightarrow U \rightarrow V \rightarrow P]$  where

$$\begin{array}{ccc} U & \longrightarrow & V \\ \downarrow & \lrcorner & \downarrow \\ A & \longrightarrow & B \end{array} .$$

The unit of the adjunction  $P \rightarrow L^*L_!P$  is given by  $(A \rightarrow P) \mapsto [LA \hookrightarrow A \rightarrow P]$ .

For  $P \in |\widetilde{\mathcal{A}}|$ , it follows by construction that  $L_!P \in |\widetilde{\mathcal{A}}|$ ; moreover  $P \hookrightarrow L_!P$  given by  $(A \rightarrow P) \mapsto [A \hookrightarrow A \rightarrow P]$  is a classifier of  $\top$ -partial maps with target  $P$  in  $\widetilde{\mathcal{A}}$ .

(2) As  $\widetilde{\mathcal{A}} \hookrightarrow \widehat{\mathcal{A}}$  preserves non-empty connected colimits, for  $\mathcal{G}$  non-empty and connected, every colimiting cone  $\gamma : \Delta \dashrightarrow Q : \mathcal{G} \rightarrow \widetilde{\mathcal{A}}$  is colimiting in  $\widehat{\mathcal{A}}$  and, as  $L_!$  is a left adjoint, also  $L_!\gamma : L_!\Delta \dashrightarrow L_!Q$  is colimiting in  $\widehat{\mathcal{A}}$ . Thus,  $L\gamma : L\Delta \dashrightarrow LQ$  is colimiting in  $\widetilde{\mathcal{A}}$ .  $\square$

*Remark.* Note that the proof of Theorem 1.7 (1) provides an *explicit* description of the lifting monad.

## 1.2 Tensor products and linear exponentials

We summarise standard material on tensor products and linear exponentials in categories of Eilenberg-Moore algebras (see [20, 21, 6, 18]) and study them in categories of lift-algebras over presheaf toposes.

Let  $\mathbb{T} = (\mathbb{T}, \eta, \mu, \text{st})$  be a commutative monad on a cartesian category  $\mathcal{C}$ . We write  $\text{st}'$  for the composite  $T(A) \times B \cong B \times T(A) \xrightarrow{\text{st}} T(B \times A) \cong T(A \times B)$  and  $\text{dst}$  for either of the composites

$$\begin{aligned} (T(A) \times T(B) &\xrightarrow{\text{st}'} T(A \times TB) \xrightarrow{T\text{st}} T^2(A \times B) \xrightarrow{\mu} T(A \times B)) \\ &= (T(A) \times T(B) \xrightarrow{\text{st}} T(TA \times B) \xrightarrow{T\text{st}'} T^2(A \times B) \xrightarrow{\mu} T(A \times B)). \end{aligned}$$

The category of Eilenberg-Moore algebras and homomorphisms for a monad  $\mathbb{T}$  on a category  $\mathcal{C}$  is denoted  $\mathcal{C}^{\mathbb{T}}$ . The structure map on an algebra  $X$  is denoted by  $\rho_X$  but generally left implicit. Algebra homomorphisms are indicated by  $\circ\rightarrow$ . When we write  $X \circ\rightarrow Y$ , the objects  $X$  and  $Y$  are assumed to be algebras. For every object  $A$  and algebras  $X, Y$ , the objects  $TA$  and  $X \times Y$  are algebras with  $\rho_{TA}$  and  $\rho_{X \times Y}$  respectively taken to be  $\mu_A$  and  $\langle \rho_X \circ T\pi_1, \rho_Y \circ T\pi_2 \rangle$ .

For algebras  $X, Y, Z$ , a map  $h : X \times Y \rightarrow Z$  said to be a *bihomomorphism* whenever

$$\begin{aligned} & (T(X) \times T(Y) \xrightarrow{\rho_X \times \rho_Y} X \times Y \xrightarrow{h} Z) \\ &= (T(X) \times T(Y) \xrightarrow{\text{dst}} T(X \times Y) \xrightarrow{Th} TZ \xrightarrow{\rho_Z} Z). \end{aligned}$$

Bihomomorphisms will be indicated by  $\infty\rightarrow$ . The *tensor product* of algebras  $X$  and  $Y$ , is defined as the universal bihomomorphism  $X \times Y \infty\rightarrow X \otimes Y$ ; that is, for every bihomomorphism  $X \times Y \infty\rightarrow Z$  there exists a unique homomorphism  $X \otimes Y \circ\rightarrow Z$  such that  $(X \times Y \infty\rightarrow X \otimes Y \circ\rightarrow Z) = (X \times Y \infty\rightarrow Z)$ . If  $\mathcal{C}^{\mathbb{T}}$  has all tensor products then  $\otimes$  endows  $\mathcal{C}^{\mathbb{T}}$  with a symmetric monoidal structure with unit  $T1$ . The map  $\text{dst} : T(A) \times T(B) \infty\rightarrow T(A \times B)$  is a bihomomorphism and its unique extension  $T(A) \otimes T(B) \circ\rightarrow T(A \times B)$  is an isomorphism with inverse  $T(A \times B) \xrightarrow{\langle T\pi_1, T\pi_2 \rangle} T(A) \times T(B) \infty\rightarrow T(A) \otimes T(B)$ . Thus, the adjunction  $\mathcal{C} \xrightarrow{\perp} \mathcal{C}^{\mathbb{T}}$  is monoidal (in the sense of [7]). *Linear exponentials*, denoted with  $\circ\Rightarrow$ , are defined as the closed structure associated to tensor products (i.e. by the adjoint situation  $\_ \otimes X \dashv X \circ\Rightarrow \_ : \mathcal{C}^{\mathbb{T}} \rightarrow \mathcal{C}^{\mathbb{T}}$ ).

If  $\mathcal{C}^{\mathbb{T}}$  has reflexive coequalisers (i.e. coequalisers of parallel pairs  $f, g : X \rightrightarrows Y$  for which there exists  $h : Y \rightarrow X$  such that  $f \circ h = \text{id} = g \circ h$ ) one can define tensor products for every pair of algebras; viz. as the coequaliser in  $\mathcal{C}^{\mathbb{T}}$  of  $T(T(X) \times T(Y)) \xrightarrow[\text{T}(\rho_X \times \rho_Y)]{\mu \circ T\text{dst}} T(X \times Y)$ . A simple situation under which this may be applied is given by the following proposition.

**Proposition 1.8.** *If  $\mathcal{C}$  has (reflexive) coequalisers and  $T$  preserves them then  $\mathcal{C}^{\mathbb{T}}$  has (reflexive) coequalisers.  $\square$*

If  $\mathcal{C}$  is cartesian closed then the action of the functor  $T$  on morphisms can be *internalised* as a map  $\underline{T}_{A,B} : B^A \rightarrow TB^{TA}$  defined as the exponential transpose of the composite  $B^A \times TA \xrightarrow{\text{st}} T(B^A \times A) \xrightarrow{Te} TB$ , where  $e$  denotes the evaluation map. If, in addition,  $\mathcal{C}$  has equalisers we can define  $X \circ\Rightarrow Y$  as the equaliser of  $Y^X \xrightarrow[\rho_Y^{TX} \circ \underline{T}_{X,Y}]{Y^{\rho_X}} Y^{TX}$  in  $\mathcal{C}$  with  $\rho_X \circ\Rightarrow Y$  the unique map, given by the universal property of equalisers, such that

$$\begin{aligned} & (T(X \circ\Rightarrow Y) \xrightarrow{\rho_X \circ\Rightarrow Y} X \circ\Rightarrow Y \xrightarrow{i} Y^X) \\ &= (T(X \circ\Rightarrow Y) \xrightarrow{Ti} T(Y^X) \xrightarrow{\lambda(T(e)\text{ost}')} TY^X \xrightarrow{\rho_Y^X} Y^X). \end{aligned}$$

In the context of the lifting monad over a presheaf topos we have:

**Corollary 1.9.** *Let  $\mathcal{A}$  be a small category with a strict initial object  $\mathbf{0}$  and a dominance  $\top : \mathbf{1} \hookrightarrow \Sigma$  for which the map  $\mathbf{0} \rightarrow \mathbf{1}$  is a  $\top$ -subobject. Then,  $\tilde{\mathcal{A}}^{\mathbb{L}}$  has a symmetric monoidal closed structure given by  $\Sigma$ , tensor products, and linear exponentials. Moreover, the adjunction  $\tilde{\mathcal{A}} \xrightarrow{\perp} \tilde{\mathcal{A}}^{\mathbb{L}}$  is monoidal.  $\square$*

### 1.3 Partial products and Kleisli exponentials

Let  $\mathbb{T}$  be a commutative monad on a cartesian category  $\mathcal{C}$ . The *partial product* functor  $- \otimes = : \mathcal{C}_{\mathbb{T}} \times \mathcal{C}_{\mathbb{T}} \rightarrow \mathcal{C}_{\mathbb{T}}$  acts as  $(A, B) \mapsto A \times B$  on objects and as  $(f, g) \mapsto \text{dst} \circ (f \times g)$  on morphisms. As usual for higher types, exponentiation arises as a right adjoint to multiplication. In this case for every  $A \in |\mathcal{C}|$ , we set  $- \otimes A \dashv A \rightrightarrows - : \mathcal{C}_{\mathbb{T}} \rightarrow \mathcal{C}$  and call  $A \rightrightarrows B$ , whenever it exists, the *Kleisli exponential*. When  $\mathcal{C}$  is cartesian closed,  $A \rightrightarrows B$  exists and is simply given by  $(TB)^A$ . Moreover, the partial product and Kleisli exponential functors are  $\mathcal{C}$ -enriched and permit the interpretation of *simple types* in  $\mathcal{C}_{\mathbb{T}}$  [24].

### 1.4 Algebraic compactness

*Algebraically compact categories* [15] axiomatise the mathematical universes allowing a universal interpretation of recursive types. We recall the notion of algebraic compactness in an enriched setting as in [8].

**Definition 1.10.** (c.f. [15])

1. **(Invariant object)** An *invariant object* of an endofunctor  $F$  is specified by an isomorphism  $FX \cong X$ .
2. **(Free invariant object)** For an endofunctor, an invariant object is said to be *free* if it is both an initial algebra and a final coalgebra.
3. **(Algebraic compactness)** For a cartesian category  $\mathcal{V}$ , a  $\mathcal{V}$ -category is said to be  *$\mathcal{V}$ -algebraically compact* if (the underlying endofunctor of) every  $\mathcal{V}$ -endofunctor on it admits a free invariant object.  $\square$

*Remark.* In general a stronger definition of algebraic compactness based on a notion of *parametric* free invariant object [28, 29] is more appropriate; however we do not go into the details here, as in the context of this paper both definitions are equivalent.

### 1.5 Kleisli ADT models

After introducing the notion of *inductive fixed-point object* we will be in a position to define Kleisli ADT models.

**Definition 1.11.** Consider a category with an initial object and a dominance.

1. We let  $\Lambda$  be the chain  $\langle L^n(\mathbf{0} \rightarrow \mathbf{1}) \rangle$  and, for every  $L$ -algebra  $\alpha : LA \rightarrow A$ , we define the cone  $\langle \alpha \rangle : \Lambda \dashv A$  inductively as follows:  $\langle \alpha \rangle_0 \stackrel{\text{def}}{=} (\mathbf{0} \rightarrow A)$  and  $\langle \alpha \rangle_{n+1} \stackrel{\text{def}}{=} L^{n+1}\mathbf{0} \xrightarrow{L\langle \alpha \rangle_n} LA \xrightarrow{\alpha} A$ .

2. **(Inductive fixed-point object)** An *inductive fixed-point object* consists of an  $L$ -invariant object  $\sigma : L\bar{\omega} \cong \bar{\omega}$  together with a global element  $1 \rightarrow \bar{\omega}$  such that the cone  $\langle \sigma \rangle : A \rightarrow \bar{\omega}$  is colimiting and  $(1 \rightarrow \bar{\omega} \xrightarrow{\text{succ}} \bar{\omega}) = (1 \rightarrow \bar{\omega})$  where  $\text{succ} \stackrel{\text{def}}{=} (\bar{\omega} \xrightarrow{\eta_{\bar{\omega}}} L\bar{\omega} \cong \bar{\omega})$ .  $\square$

The essential difference between our fixed-point object and the one previously considered in [5] is its *inductive* nature, in that we require it to arise as the colimit of the standard chain generated by iterating the lifting functor.

- Definition 1.12.** 1. **(Monadic base)** A *(lifting) monadic (enrichment) base* is given by a category  $\mathcal{C}$  equipped with an initial object, a cartesian closed structure, a dominance, and an inductive fixed-point object such that  $\mathcal{C}^{\mathbb{L}}$  has tensor products and linear exponentials.
2. **(KADT model)** For a monadic base  $\mathcal{C}$ ,  $\mathcal{C}_{\mathbb{L}}$  is said to be a *Kleisli ADT model* if it is  $\mathcal{C}$ -algebraically compact.  $\square$

KADT models with finite coproducts yield *models of FPC* (as in [8, Definition 8.3.1]) and hence allow the interpretation of the metalanguage FPC [27].

*Remark.* A subtle consequence of the above definition is that the map  $0 \rightarrow 1$  is a  $\top$ -subobject. Indeed, observing that  $0$  is initial, and hence also terminal, in  $\mathcal{C}_{\mathbb{L}}$  (as  $\mathcal{C}_{\mathbb{L}}$  is  $\mathcal{C}$ -algebraically compact), the claim follows from the existence of a partial map  $1 \rightarrow 0$  using that  $0$  is strict. Hence, the dominance  $\top : 1 \hookrightarrow \Sigma$  cannot be trivial unless  $\mathcal{C}$  is.

Algebraic compactness may be achieved under certain completeness conditions (see e.g. [8, 28]) for so-called *ep-sequences*. Rather than defining ep-sequences we will observe the following which we need later.

Let  $\mathcal{C}$  be a monadic base and let  $\mathcal{K}$  be a  $\mathcal{C}^{\mathbb{L}}$ -category.

1. Ep-sequences in  $\mathcal{K}$  are chains of retractions equipped with certain extra structure.
2. In  $\mathcal{K}$  the limit/colimit coincidence [35] holds for ep-sequences [28].
3. Assuming that  $\mathcal{K}$  has an enriched zero object  $0$ , every  $\mathcal{C}$ -endofunctor  $F$  on  $\mathcal{K}$  induces the *standard* ep-sequence  $\langle F^n(0 \hookrightarrow F0) \rangle$  whose bilimit, whenever it exists, is preserved by the functor.

**Theorem 1.13.** ([28]) *If  $\mathcal{K}$  has an enriched zero object and bilimits of ep-sequences then it is  $\mathcal{C}$ -algebraically compact.*  $\square$

For a monadic base  $\mathcal{C}$ , we may apply the above remarks to the  $\mathcal{C}$ -endofunctor  $L$  on  $\mathcal{C}^{\mathbb{L}}$ . Writing  $\top : 1 \hookrightarrow \Sigma$  for the dominance, the standard ep-sequence induced by  $L$  is  $\langle L^n(1 \hookrightarrow \Sigma) \rangle$  with  $\langle L^n(1 \hookrightarrow \Sigma) \rangle = LA$  (see Definition 1.11 (1)). Moreover, writing  $\sigma : L\bar{\omega} \cong \bar{\omega}$  for the inductive fixed-point object, since the cone  $\langle \sigma \rangle : A \rightarrow \bar{\omega}$  is colimiting in  $\mathcal{C}$  and the free functor  $\mathcal{C} \rightarrow \mathcal{C}^{\mathbb{L}}$  preserves colimits it follows that  $L\langle \sigma \rangle : LA \hookrightarrow L\bar{\omega}$  is colimiting in  $\mathcal{C}^{\mathbb{L}}$ . Now, by the limit/colimit coincidence, the cocone  $\pi : L\bar{\omega} \hookrightarrow \langle L^n(1 \hookrightarrow \Sigma) \rangle$  induced by the coalgebra

$L\sigma^{-1}$  (i.e. defined by  $\pi_0 \stackrel{\text{def}}{=} (L\bar{\omega} \circ \rightarrow 1)$  and  $\pi_{n+1} \stackrel{\text{def}}{=} L(\pi_n \circ \sigma^{-1})$ ) is limiting in  $\mathcal{C}^{\mathbb{L}}$ . Finally, as the forgetful functor  $\mathcal{C}^{\mathbb{L}} \rightarrow \mathcal{C}$  preserves limits, we have that

$$\pi \circ \sigma : \bar{\omega} \cong L\bar{\omega} \dashrightarrow \langle L^n(1 \leftarrow \Sigma) \rangle \text{ is limiting in } \mathcal{C}; \quad (2)$$

and hence  $L\bar{\omega} \cong \bar{\omega}$  is a free  $L$ -invariant object. Thus, in a monadic base the global element  $1 \rightarrow \bar{\omega}$  of the inductive fixed-point object is characterised by the equation  $(1 \rightarrow \bar{\omega} \xrightarrow{\text{succ}} \bar{\omega}) = (1 \rightarrow \bar{\omega})$ .

## 2 Synthetic domain theory

We develop a non-elementary version of SDT. On the one hand, we follow closely the approach of Longley and Simpson [22, 23] in that we adopt their *completeness axiom* (Axiom 1) and identify domains with *well-complete* objects (Definition 2.6 (2)); on the other hand, we depart notably from their approach in that we impose a non-elementary axiom (Axiom 3) stating that the initial lift-algebra in the ambient topos is *inductive*, in that it arises as a colimit of the standard chain.

### 2.1 Orthogonality

*Orthogonality* [12] plays a crucial rôle in understanding well-complete objects (see Theorem 2.7 (1)), in this subsection we recall the notion together with various useful observations about it.

**Definition 2.1 (Orthogonality).** 1. An object  $A$  is said to be *orthogonal* to a map  $D \rightarrow C$  whenever for every map  $D \rightarrow A$  there exists a unique  $C \rightarrow A$  such that  $(D \rightarrow A) = (D \rightarrow C \rightarrow A)$ .

For a category  $\mathcal{C}$  and a class  $J$  of maps in it we define  $\mathbf{O}(\mathcal{C}, J)$  as the full subcategory of  $\mathcal{C}$  consisting of all those objects orthogonal to every map in  $J$ .

2. In a cartesian closed category, an object  $A$  is *internally orthogonal* to a map  $g : D \rightarrow C$  whenever  $A^g : A^C \rightarrow A^D$  is iso.  $\square$

Intuitively, an object is orthogonal to a map whenever it *believes* (or, as Lawvere will put it, *perceives*) that the map is iso. Internal orthogonality corresponds to a *parameterised* version of orthogonality.

**Proposition 2.2.** *In a cartesian closed category  $\mathcal{C}$ ,*

1. *An object is internally orthogonal to a map  $g$  if and only if it is orthogonal to  $g \times C$ , for every object  $C$ .*
2. *For a colimiting cone  $\Delta \dashrightarrow C : \mathcal{G} \rightarrow \mathcal{C}$ , if an object is orthogonal to  $g \times \Delta_n$  for every  $n \in |\mathcal{G}|$ , then it is orthogonal to  $g \times C$ .*  $\square$

**Proposition 2.3.** 1. If an object is orthogonal to a map then so is every retract of the object.

2. The embedding  $\mathbf{O}(\mathcal{C}, J) \hookrightarrow \mathcal{C}$  creates limits.  $\square$

**Proposition 2.4.** Let  $\mathcal{C}$  be a cartesian closed category and let  $J$  be a class of maps in  $\mathcal{C}$  satisfying the following closure property:

(Parameterisation) For  $g \in J$  and  $C \in |\mathcal{C}|$ ,  $g \times C \in J$ .

Then,  $\mathbf{O}(\mathcal{C}, J)$  is a full sub-cartesian exponential ideal of  $\mathcal{C}$ .  $\square$

## 2.2 SDT models

We assume a topos  $\mathcal{S}$  with NNO  $\mathbb{N}$  and equipped with a dominance  $\top : 1 \hookrightarrow \Sigma$ . We have that  $\Sigma$  is a subobject of the subobject classifier  $\Omega$ ; in fact,

$$\begin{array}{ccc} 1 & \longrightarrow & 1 \\ \top \downarrow & \lrcorner & \downarrow \text{true} \\ \Sigma & \twoheadrightarrow & \Omega \end{array} .$$

The following is *folklore* [31, 19, 34]:

**Proposition 2.5.** The lifting functor  $L$  has an initial algebra  $\iota : L1 \cong 1$  and a final coalgebra  $\varphi : F \cong LF$  with a unique global element  $1 \rightarrow F$  such that  $(1 \rightarrow F \xrightarrow{\eta_F} LF \cong F) = (1 \rightarrow F)$ . Moreover, the canonical map  $\kappa : 1 \rightarrow F$  (characterised by the equation  $L\kappa = \varphi \circ \kappa \circ \iota$ ) is mono.  $\square$

We have the following internal description:

$$F = \{p \in \Sigma^{\mathbb{N}} \mid \forall n \in \mathbb{N}. p_{n+1} \Rightarrow p_n\}$$

and so the inclusion  $F \subseteq \Sigma^{\mathbb{N}}$  is a section with retraction  $\Sigma^{\mathbb{N}} \rightarrow F$  mapping  $f$  to  $\lambda n \in \mathbb{N}. \bigwedge_{0 \leq i \leq n} f_i$ .

**Definition 2.6.** ([22, 23])

1. (**Complete object**) An object is *complete* whenever it is internally orthogonal to the canonical map  $1 \twoheadrightarrow F$ .
2. (**Well-complete object**) An object  $A$  is *well-complete* whenever  $LA$  is complete.

We write  $\mathbf{WC}(\mathcal{S})$  for the full subcategory of well-complete objects in  $\mathcal{S}$ .  $\square$

Intuitively, an object  $A$  is complete whenever it believes that every “parameterised l-chain in  $A$ ” has a unique “extension” to a “parameterised F-chain in  $A$ ” (see Proposition 2.2 (1)).

Notice that an object  $A$  is well-complete if and only if it is orthogonal, with respect to  $\top$ -partial maps, to  $\kappa \times C : 1 \times C \twoheadrightarrow F \times C$  for every  $C$ . That is, when for every  $\top$ -partial map  $1 \times C \hookrightarrow A$  there exists a unique  $\top$ -partial map  $F \times C \hookrightarrow A$  such that  $(1 \times C \hookrightarrow A) = (1 \times C \twoheadrightarrow F \times C \hookrightarrow A)$ .

**Axiom 1 (Completeness axiom [23]).**  $\Sigma$  is complete. □

The completeness axiom establishes, for every  $C \in |\mathcal{S}|$ , a bijective correspondence

$$(\kappa \times C)^{-1}(-) : \Sigma\text{Sub}(\mathbf{F} \times C) \cong \mathcal{S}(\mathbf{F} \times C, \Sigma) \cong \mathcal{S}(\mathbf{I} \times C, \Sigma) \cong \Sigma\text{Sub}(\mathbf{I} \times C) \quad (3)$$

$$f \mapsto f \circ (\kappa \times C)$$

where  $\Sigma\text{Sub}(A)$  denotes the collection of  $\top$ -subobjects of  $A$ .

We characterise well-completeness in terms of orthogonality and study closure properties of well-complete objects.

**Theorem 2.7. 1. (Intrinsic characterisation of WC)** For  $\mathbf{J}$  the smallest family of maps in  $\mathcal{S}$  containing the canonical map  $\mathbf{I} \twoheadrightarrow \mathbf{F}$  and satisfying the following closure properties:

(Parameterisation) For  $g \in \mathbf{J}$  and  $C \in |\mathcal{S}|$ ,  $g \times C \in \mathbf{J}$ .

(Stability) For  $D \rightarrow C$  in  $\mathbf{J}$  and  $U \hookrightarrow C$  a  $\top$ -subobject,

$$\begin{array}{ccc} V & \twoheadrightarrow & U \\ \downarrow \lrcorner & & \downarrow \\ D & \twoheadrightarrow & C \end{array} \Rightarrow V \rightarrow U \text{ in } \mathbf{J},$$

we have  $\mathbf{WC}(\mathcal{S}) = \mathbf{O}(\mathcal{S}, \mathbf{J})$ .

2. (c.f. [23])  $\Sigma$  is well-complete.
3. (c.f. [23])  $\mathbf{WC}(\mathcal{S})$  is closed under lifting.
4. (c.f. [23]) Well-complete objects are also complete.

*Proof.* (1) First observe that

$$\mathbf{J} = \{V \hookrightarrow U \mid \begin{array}{ccc} V & \twoheadrightarrow & U \\ \downarrow \lrcorner & & \downarrow \\ \mathbf{I} \times C & \twoheadrightarrow_{\kappa \times C} & \mathbf{F} \times C \end{array} C \in |\mathcal{S}|\}.$$

( $\subseteq$ ) Let  $A$  be a well-complete object. In the situation

$$\begin{array}{ccc} V & \twoheadrightarrow & U \\ \downarrow \lrcorner & & \downarrow \\ \mathbf{I} \times C & \twoheadrightarrow_{\kappa \times C} & \mathbf{F} \times C \end{array}$$

every map  $V \rightarrow A$  yields the  $\top$ -partial map  $[\mathbf{I} \times C \hookrightarrow V \rightarrow A]$  with a unique extension  $[\mathbf{F} \times C \hookrightarrow W \rightarrow A]$  such that

$$\begin{array}{ccc} V & \twoheadrightarrow & W \\ \downarrow \lrcorner & & \downarrow \\ \mathbf{I} \times C & \twoheadrightarrow_{\kappa \times C} & \mathbf{F} \times C \end{array} \quad \text{and} \quad (V \rightarrow A) = (V \twoheadrightarrow W \rightarrow A).$$

And since, by (3),  $[W \hookrightarrow \mathbf{F} \times C] = [U \hookrightarrow \mathbf{F} \times C]$  we are done.

( $\supseteq$ ) For a  $\top$ -partial map  $[I \times C \hookrightarrow V \rightarrow A]$ , by (3) and orthogonality, there exist unique  $U \hookrightarrow \mathbf{F} \times C$  and  $U \rightarrow A$  such that

$$\begin{array}{ccc} V & \xrightarrow{\quad} & U \\ \downarrow \lrcorner & & \downarrow \\ I \times C & \xrightarrow[\kappa \times C]{} & \mathbf{F} \times C \end{array} \text{ and } (V \rightarrow A) = (V \twoheadrightarrow U \rightarrow A);$$

hence we are done.

(2) Because in the situation

$$\begin{array}{ccc} V & \xrightarrow{\quad} & U \\ \downarrow \lrcorner & & \downarrow \\ I \times C & \xrightarrow[\kappa \times C]{} & \mathbf{F} \times C \end{array}$$

we have  $(V \rightarrow \Sigma) = (V \twoheadrightarrow U \rightarrow \Sigma)$  if and only if  $(U \rightarrow \Sigma) = (U \hookrightarrow \mathbf{F} \times C \rightarrow \Sigma)$  where

$$\begin{array}{ccc} V & \longrightarrow & \mathbf{1} \\ \downarrow \lrcorner & & \downarrow \top \\ I \times C & \longrightarrow & \Sigma \end{array} \text{ and } (I \times C \rightarrow \Sigma) = (I \times C \xrightarrow{\kappa \times C} \mathbf{F} \times C \rightarrow \Sigma).$$

(3) Using that  $\Sigma$  is well-complete and the closure under (Stability) of  $\mathbf{J}$  one can adapt the argument of Proposition 1.6 to well-completeness (see [9, Lemma 11.16]).

(4) A well-complete object  $A$  is also complete, by Proposition 2.2 (1) and 2.3 (2) because

$$\begin{array}{ccc} A & \longrightarrow & \mathbf{1} \\ \downarrow \lrcorner & & \downarrow \\ LA & \longrightarrow & \Sigma \end{array}$$

in  $\mathcal{S}$ . □

**Corollary 2.8.** *Let  $\mathcal{W}$  be a subcategory of  $\mathcal{S}$  containing the terminal object and closed under lifting. Then, the following are equivalent:*

- *Every object in  $\mathcal{W}$  is well-complete.*
- *Every object in  $\mathcal{W}$  is complete.*

*If, in addition,  $\mathcal{W}$  is an exponential ideal of  $\mathcal{S}$  then a further equivalent statement is:*

- *Every object in  $\mathcal{W}$  is orthogonal to the canonical map  $I \twoheadrightarrow \mathbf{F}$ .* □

**Corollary 2.9.** (c.f. [23])

1.  $\mathbf{WC}(\mathcal{S})$  is a full sub-cartesian exponential ideal of  $\mathcal{S}$ .
2.  $\varphi : \mathbf{F} \cong LF$  remains a final  $L$ -coalgebra in  $\mathbf{WC}(\mathcal{S})$ .

*Proof.* (1) By Proposition 2.4 and Theorem 2.7 (1).

(2) Because  $\mathbf{F}$  is a retract of  $\Sigma^{\mathbb{N}}$  which, by Corollary 2.9 (1), is well-complete.  $\square$

**Axiom 2** ([17]). The map  $0 \rightarrow 1$  is a  $\top$ -subobject.  $\square$

**Corollary 2.10.** The initial object in  $\mathcal{S}$  is also initial in  $\mathbf{WC}(\mathcal{S})$ .

*Proof.* By Proposition 2.3 (2) because, by Axiom 2,

$$\begin{array}{ccc} 0 & \hookrightarrow & 1 \\ \downarrow & \lrcorner & \downarrow \top \\ 1 & \longrightarrow & \Sigma \end{array}$$

in  $\mathcal{S}$ .  $\square$

**Proposition 2.11.** ([23]) In  $\mathbf{WC}(\mathcal{S})$ ,  $\varphi^{-1} : LF \cong \mathbf{F}$  is an initial  $L$ -algebra; and hence is free.  $\square$

Our main means for relating axiomatic and synthetic domain theory is the following axiom.

**Axiom 3.** The cone  $\langle \iota \rangle : A \rightarrow \mathbf{1}$  (see Definition 1.11 (1)) is colimiting in  $\mathcal{S}$ .  $\square$

**Proposition 2.12.** In  $\mathbf{WC}(\mathcal{S})$ , the cone  $\langle \varphi^{-1} \rangle : A \rightarrow \mathbf{F}$  is colimiting; and hence  $\mathbf{F}$  becomes an inductive fixed-point object.

*Proof.* Let  $\gamma : A \rightarrow C$  be a cone with  $C$  a well-complete object. As  $\kappa$  is the unique mediating morphism between  $\langle \iota \rangle$  and  $\langle \varphi^{-1} \rangle$  and  $C$  is orthogonal to it, we have that a map  $\mathbf{F} \rightarrow C$  mediates between  $\langle \varphi^{-1} \rangle$  and  $\gamma$  if and only if, for  $\mathbf{1} \rightarrow C$  the unique mediating morphism between  $\langle \iota \rangle$  and  $\gamma$ ,  $(\mathbf{1} \rightarrow C) = (\mathbf{1} \xrightarrow{\kappa} \mathbf{F} \rightarrow C)$ .  $\square$

Finally, we are in a position to define Grothendieck SDT models.

**Definition 2.13 (GSdT model).** A *Grothendieck SDT model* is given by a Grothendieck topos equipped with a dominance such that its induced lifting functor has rank (i.e. it preserves  $\alpha$ -filtered colimits for some regular cardinal  $\alpha$ ), in which Axioms 1–3 hold.  $\square$

*Remark.* The above should only be taken as a working definition. For example, if in the notion of GSdT model we replace the condition “the lifting functor has rank” by “the lifting functor preserves reflexive coequalisers” our results remain valid.

As lifting preserves non-empty connected limits [17, Proposition 2.2.1], in GSDT models the final lift-coalgebra can be computed as the limit of the chain  $\langle L^n(1 \leftarrow \Sigma) \rangle$ .

*Example 2.14.* The presheaf toposes on

1. the monoid of *continuous* endomorphisms on  $\omega + 1$ , and
2. the monoid of *stable* endomorphisms on  $(\omega + 1) \times 2$  (where 2 denotes the Sierpinski space)

are GSDT models.

*Remark.* Refinements of these models have been introduced and studied in [14].  $\square$

In GSDT models, an *extrinsic* characterisation of the well-complete objects is available.

**Theorem 2.15 (Extrinsic characterisation of WC).** *For a GSDT model  $\mathcal{S}$ ,  $\mathbf{WC}(\mathcal{S})$  is the largest full sub-cartesian reflective exponential ideal of  $\mathcal{S}$  closed under lifting and such that the reflection of the initial lift-algebra is free.*

*Proof.* We only show that  $\mathbf{WC}(\mathcal{S})$  is reflective in  $\mathcal{S}$ . We will use the following: for a locally presentable category  $\mathcal{C}$  and a set  $J$  of maps in it,  $\mathbf{O}(\mathcal{C}, J)$  is reflective in  $\mathcal{C}$  (see [4, Corollary I.5.4.8]).

Since Grothendieck toposes are locally presentable, it is enough to show that  $\mathbf{WC}(\mathcal{S}) = \mathbf{O}(\mathcal{S}, \mathbf{J}_P)$  for some set  $\mathbf{J}_P$ . Indeed, we may take

$$\mathbf{J}_P = \left\{ V \hookrightarrow U \mid \begin{array}{ccc} V & \xrightarrow{\quad} & U \\ \downarrow \lrcorner & & \downarrow \\ \mathbf{I} \times C & \xrightarrow[\kappa \times C]{} & \mathbf{F} \times C \end{array} \quad C \in \mathbf{PS} \right\}.$$

where  $\mathbf{PS}$  is a set of representatives of the presentable objects in  $\mathcal{S}$ .

It also follows that  $\mathbf{WC}(\mathcal{S})$  is locally presentable (see [1, 1.40]).  $\square$

*Remark.* Theorem 2.15 does not rely on the rank condition on the lifting functor.

### 3 Relating ADT and SDT

We relate models of axiomatic and synthetic domain theory. On the one hand, in Subsection 3.1, for every GSDT model  $\mathcal{S}$ , we establish that  $\mathbf{WC}(\mathcal{S})$  is a monadic base and that  $\mathbf{WC}(\mathcal{S})_{\perp}$  is a KADT model. On the other hand, in Subsection 3.2, for every *small* monadic base  $\mathcal{C}$  yielding a KADT model, we show that  $\tilde{\mathcal{C}}$  is a GSDT model such that its associated monadic base  $\mathbf{WC}(\tilde{\mathcal{C}})$  and KADT model *conservatively extend* those of  $\mathcal{C}$ .

Our restriction to *small* models in Subsection 3.2 should not be a serious one. More generally, one would expect to account for *locally small models* with a *small dense generator* [4, Definition I.4.5.4]. And this situation is general enough to cover such traditional categories of domains as  $\mathbf{Cpo}$  and  $\mathbf{Cpo}_\wedge$  (the category of small cpos with continuous pullbacks and stable functions), for which one may respectively take the monoids of Example 2.14 as dense generators.

### 3.1 Restricting SDT models to ADT models

The domains in a GSDT model yield a KADT model.

**Theorem 3.1.** *For a GSDT model  $\mathcal{S}$ ,  $\mathbf{WC}(\mathcal{S})$  is a monadic base and  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$  is a KADT model.*

*Proof.*  $\mathbf{WC}(\mathcal{S})$  has the required structure by Corollaries 2.9 and 2.10, Theorem 2.7 (2)–(3), and Proposition 2.12;  $\mathbf{WC}(\mathcal{S})^{\mathbb{L}}$  admits tensor products and linear exponentials because it is locally presentable (and hence complete and cocomplete) as so is  $\mathcal{S}^{\mathbb{L}}$  (because  $\mathcal{S}$  is locally presentable and  $L$  has rank — see [4, Proposition II.4.3.6] and [1, 2.78]) and  $\mathbf{WC}(\mathcal{S})^{\mathbb{L}} = \mathbf{O}(\mathcal{S}^{\mathbb{L}}, F^{\mathbb{L}}\mathbf{J}_{\mathcal{P}})$  where  $F^{\mathbb{L}}\mathbf{J}_{\mathcal{P}}$  is the image of  $\mathbf{J}_{\mathcal{P}}$  under the *free* functor  $\mathcal{S} \rightarrow \mathcal{S}^{\mathbb{L}}$ ; finally to see that  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$  is  $\mathbf{WC}(\mathcal{S})$ -algebraically compact, by Theorem 1.13, it suffices to show that  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$  has bilimits of ep-sequences. For a quick argument observe that the cocompleteness of  $\mathbf{WC}(\mathcal{S})$  and the following:

**Theorem 3.2.** *([8, Theorem 5.3.14]) Let  $\mathcal{C}$  be a category with a dominance. For a diagram  $\Delta$  in  $\mathcal{C}$ , if  $L\Delta$  has colimit in  $\mathcal{C}$  then  $\Delta$  has colimit in  $\mathcal{C}_{\mathbb{L}}$ .  $\square$*

imply that every diagram in  $\mathbf{WC}(\mathcal{S})$  has colimit in  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$ . Then, as ep-sequences are chains of retractions, every ep-sequence in  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$  has sections in  $\mathbf{WC}(\mathcal{S})$  and hence we are done.

*Remark.* An argument that relies on the completeness (rather than the cocompleteness) of  $\mathbf{WC}(\mathcal{S})$  is also available: for every ep-sequence  $\langle A_n \hookrightarrow A_{n+1} \rangle$  in  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$ , the sequence  $\langle L(A_n \hookrightarrow A_{n+1}) \rangle$  is an ep-sequence in  $\mathbf{WC}(\mathcal{S})$  (because  $L : \mathbf{WC}(\mathcal{S})_{\mathbb{L}} \rightarrow \mathbf{WC}(\mathcal{S})$  is  $\mathbf{WC}(\mathcal{S})$ -enriched) and since  $\langle L(A_n \hookrightarrow A_{n+1}) \rangle$  has limit in  $\mathbf{WC}(\mathcal{S})$ , by the limit/colimit coincidence,  $\langle L(A_n \rightarrow A_{n+1}) \rangle$  has colimit in  $\mathbf{WC}(\mathcal{S})$  and, by Theorem 3.2,  $\langle A_n \rightarrow A_{n+1} \rangle$  has colimit in  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$ .  $\square$

*Remark.* In the proof of Theorem 3.1, note the use of the Grothendieck assumption on  $\mathcal{S}$  and the rank assumption on  $L$  to guarantee enough completeness and cocompleteness on  $\mathbf{WC}(\mathcal{S})$ ,  $\mathbf{WC}(\mathcal{S})^{\mathbb{L}}$  and  $\mathbf{WC}(\mathcal{S})_{\mathbb{L}}$ .

From Theorem 1.13 we further obtain:

**Corollary 3.3.** *For a GSDT model  $\mathcal{S}$ ,  $\mathbf{WC}(\mathcal{S})^{\mathbb{L}}$  is  $\mathbf{WC}(\mathcal{S})$ -algebraically compact.  $\square$*

### 3.2 Extending ADT models to SDT models

We incorporate monadic bases and KADT models to the synthetic setting via Yoneda:

**Theorem 3.4 (Conservative-extension theorem).** *Let  $\mathcal{C}$  be a small monadic base yielding a KADT model.*

1. *The Yoneda embedding  $\mathcal{C} \hookrightarrow \tilde{\mathcal{C}}$  preserves the initial object, limits, exponentials, the final lift-coalgebra, and the dominance. Moreover,*

$$\begin{array}{ccc} \mathcal{C} & \hookrightarrow & \tilde{\mathcal{C}} \\ L \downarrow & & \downarrow L \\ \mathcal{C} & \hookrightarrow & \tilde{\mathcal{C}} \end{array}$$

*commutes up to isomorphism.*

2. *The Yoneda embedding  $\mathcal{C} \hookrightarrow \tilde{\mathcal{C}}$  cuts down to an embedding  $\mathcal{C} \hookrightarrow \mathbf{WC}(\tilde{\mathcal{C}})$ .*
3. *The topos  $\tilde{\mathcal{C}}$  is a GSDT model; and hence  $\mathbf{WC}(\tilde{\mathcal{C}})$  is a monadic base yielding a KADT model.*

*The embeddings  $\mathcal{C} \hookrightarrow \mathbf{WC}(\tilde{\mathcal{C}}) \hookrightarrow \tilde{\mathcal{C}}$  preserve the initial object, limits, exponentials, the final lift-coalgebra, and the dominance. Moreover,*

$$\begin{array}{ccccc} \mathcal{C} & \hookrightarrow & \mathbf{WC}(\tilde{\mathcal{C}}) & \hookrightarrow & \tilde{\mathcal{C}} \\ L \downarrow & & L \downarrow & & \downarrow L \\ \mathcal{C} & \hookrightarrow & \mathbf{WC}(\tilde{\mathcal{C}}) & \hookrightarrow & \tilde{\mathcal{C}} \end{array}$$

*commutes up to isomorphism.*

4. *The embeddings  $\mathcal{C} \hookrightarrow \mathbf{WC}(\tilde{\mathcal{C}}) \hookrightarrow \tilde{\mathcal{C}}$  yield embeddings  $\mathcal{C}_{\perp} \hookrightarrow \mathbf{WC}(\tilde{\mathcal{C}})_{\perp} \hookrightarrow \tilde{\mathcal{C}}_{\perp}$  that preserve partial products and Kleisli exponentials. If a diagram in  $\mathcal{C}_{\perp}$  has limit both in  $\mathcal{C}_{\perp}$  and  $\mathbf{WC}(\tilde{\mathcal{C}})_{\perp}$  then the limit in  $\mathcal{C}_{\perp}$  is preserved by the embedding  $\mathcal{C}_{\perp} \hookrightarrow \mathbf{WC}(\tilde{\mathcal{C}})_{\perp}$ ; such diagrams include the cochains of retractions of standard ep-sequences.*
5. *For a  $\mathcal{C}$ -endofunctor  $F$  on  $\mathcal{C}_{\perp}$  and a  $\mathbf{WC}(\tilde{\mathcal{C}})$ -endofunctor  $F'$  on  $\mathbf{WC}(\tilde{\mathcal{C}})_{\perp}$  satisfying*

$$\begin{array}{ccc} \mathcal{C}_{\perp} & \hookrightarrow & \mathbf{WC}(\tilde{\mathcal{C}})_{\perp} \\ F \downarrow & & \downarrow F' \\ \mathcal{C}_{\perp} & \hookrightarrow & \mathbf{WC}(\tilde{\mathcal{C}})_{\perp} \end{array} ,$$

*a free  $F$ -invariant object becomes a free  $F'$ -invariant object.*

*Proof.* (1) We only note that the embedding  $\mathcal{C} \hookrightarrow \tilde{\mathcal{C}}$  preserves the final lift-coalgebra because, by (2), it is computed as a limit.

(2) By Corollary 2.8 we need only show that every object in  $\mathcal{C}$  is complete.

Recall that the lifting on  $\tilde{\mathcal{C}}$  preserves connected colimits (Theorem 1.7 (2)) and hence the cone  $\langle \iota \rangle : A \dot{\rightarrow} I$  is colimiting in  $\tilde{\mathcal{C}}$ . Moreover, writing  $\sigma : L\bar{\omega} \cong \bar{\omega}$  for the inductive fixed-point object,  $(A \xrightarrow{\langle \sigma \rangle} \bar{\omega}) = (A \xrightarrow{\langle \varphi^{-1} \rangle} F \cong \bar{\omega})$  is colimiting in  $\mathcal{C}$  and since  $(A \xrightarrow{\langle \iota \rangle} I \xrightarrow{\kappa} F) = (A \xrightarrow{\langle \varphi^{-1} \rangle} F)$  it follows that every object in  $\mathcal{C}$  is orthogonal to  $\kappa$ . The result follows from the following equivalences:

$$\begin{aligned}
& \forall D \in |\mathcal{C}|. D \text{ is orthogonal to } \kappa \\
& \text{iff } \forall D \in |\mathcal{C}|. \forall C \in |\mathcal{C}|. D^C \text{ is orthogonal to } \kappa \\
& \text{iff } \forall D \in |\mathcal{C}|. \forall C \in |\mathcal{C}|. D \text{ is orthogonal to } \kappa \times C \\
& \text{iff } \forall D \in |\mathcal{C}|. \forall P \in |\tilde{\mathcal{C}}|. D \text{ is orthogonal to } \kappa \times P \\
& \quad \text{(by Proposition 2.2 (2))} \\
& \quad \text{because every presheaf is a colimit of representables)} \\
& \text{iff } \forall D \in |\mathcal{C}|. D \text{ is complete} \\
& \quad \text{(by Proposition 2.2 (1)).}
\end{aligned}$$

(3)  $\tilde{\mathcal{C}}$  is a GSMT model by Theorems 3.4 (1) and 1.7 (2).

(4) We only consider the preservation of limits of diagrams in  $\mathcal{C}_{\mathbb{L}}$  with limits both in  $\mathcal{C}_{\mathbb{L}}$  and  $\mathbf{WC}(\tilde{\mathcal{C}})_{\mathbb{L}}$ .

Let  $D \dot{\rightarrow} \Delta : \mathcal{G} \rightarrow \mathcal{C}_{\mathbb{L}}$  and  $P \dot{\rightarrow} \Delta : \mathcal{G} \rightarrow \mathbf{WC}(\tilde{\mathcal{C}})_{\mathbb{L}}$  be limiting and let  $D \rightarrow P$  be the unique mediating morphism between them. Since the embedding  $\mathcal{C} \hookrightarrow \mathbf{WC}(\tilde{\mathcal{C}})$  and the forgetful functors  $\mathcal{C}_{\mathbb{L}} \rightarrow \mathcal{C}$  and  $\mathbf{WC}(\tilde{\mathcal{C}})_{\mathbb{L}} \rightarrow \mathbf{WC}(\tilde{\mathcal{C}})$  preserve limits, it follows that  $L(D \rightarrow P)$  is iso. Finally, as  $L$  reflects isos [8, Proposition 3.2.11 (4)], also  $D \rightarrow P$  is iso.

(5) Follows from a generalisation of [8, Theorems 7.1.5 and 7.3.11 (6)] in the context of [28].  $\square$

*Remark.* There is an alternative synthetic viewpoint of domains (à la [17, 36]) via replete objects [16]. In general a conservative-extension result in which domains are taken to be the replete objects (rather than the well-complete ones) is impossible, because embeddings that preserve dominances reflect the property of being a replete object and there are models of ADT in which not every object is replete (e.g. in the category  $\mathbf{Cpo}$  as recently discovered by Makkai and Rosolini [33], and in the category  $\mathbf{VPoset}_{\wedge}$  introduced in [10]).

## 4 Comments on our approach

This paper is an initial investigation of the relation between axiomatic and synthetic domain theory. For this, we had to restrict both the axiomatic and the synthetic (à la [22, 23]) approaches.

- On the axiomatic side, one may, more generally, work with models arising from an arbitrary commutative monad or even from a monoidal adjunction, and may also work with other models than the Kleisli category (e.g. the category of Eilenberg-Moore algebras).

Since the synthetic approach is currently restricted to lifting monads we restricted the axiomatic models to those arising from them.

- Concerning the extension of ADT models based on Eilenberg-Moore algebras to SDT models we only have partial results (among which is Corollary 3.3).
- On the synthetic side, the trend has been to investigate realisability models [30, 26, 13, 23] (though see [30, 36, 14]). Here our main means for finding models of ADT within models of SDT (via well-complete objects [23]) is a non-elementary axiom (Axiom 3) that is not satisfied in that setting. In this context it is worth noting our extrinsic characterisation of well-complete objects (Theorem 2.15) which is not known to hold of realisability models.

Therefore reconciling both approaches completely is an open problem.

**Acknowledgements.** Our approach to SDT has been shaped by ideas of Alex Simpson. Discussions with Martin Hyland and Pino Rosolini were also very helpful. The diagrams were drawn with Paul Taylor’s commutative-diagrams package.
