## ABSTRACT

**Background and Objectives:** Refugees are often further susceptible to food insecurity in host countries. This study was carried out to review food insecurity statuses of Afghan refugees in Iran.

**Materials and Methods:** A comprehensive search was carried out using keywords of "food insecurity", "food security", "Iran", "Afghan", "immigrant" and "refugee" in English databases, including Scopus, Web of Science, PubMed and Google Scholar, as well as Persian databases, including Scientific Information Database, Noor, Magiran and Irandoc, from the beginning of 2000 to the end of 2019. Prevalence of food insecurity reported in each study was recorded based on the types of questionnaires and food insecurity criteria. Meta-analysis was carried out using random effect model with publication bias and heterogeneity tests using STATA Software.

**Results:** Overall, four studies were reviewed; of which, one was carried out in two provinces of Tehran and Mashhad. Household food insecurity access scale, United States Department of Agriculture and Radimer/Cornell questionnaires were used as the measurement tools in 2, 1 and 1 studies, respectively. Prevalence of mild, moderate and severe food insecurities was reported as 11.6–16.1, 27.4–46.5 and 20–61%, respectively. Based on meta-analysis, prevalence of food insecurity in Afghan refugees in Iran was 89% (95% CI: 69–110%). Food insecurity was significantly more prevalent in Afghan immigrants with illegal residential statuses and female-headed and bigger family size households. Being Sunnis, living in various cities (Tehran and Mashhad) and duration of staying in Iran were associated with food insecurity in Afghan refugees.

**Conclusions:** The high prevalence of food insecurity in Afghan refugees in Iran reveals the necessity of policies to limit the prevalence of food insecurity in these refugees in Iran.

**Keywords:** Food security, Afghan refugees, Immigrant, Iran, Review

## Introduction

Food insecurity is defined as "ensuring physical and economic access to essential nutrients needed by all humans at all times for a healthy and active life" (1). Food insecurity is a major concern of the health issues and an indicator of health assessment and well-being (2). Refugees are often further susceptible to food insecurity in their host countries. Factors such as poor economics due to poverty, low-salary jobs, employment and educational insecurities, marginal and inappropriate social statuses and lack of valid immigration permissions are the factors that make immigrants susceptible to food insecurity (3, 4). Immigration is often a big crisis for the people and can

change their lives, leading to malnutrition and food insecurity. Within the last three decades, a large number of Afghan refugees have entered Iran. Nowadays, more than 2.5 million Afghan refugees live in Iran, accounting for 3% of the total population of Iran (5). Of Afghan refugees residing in Iran, 97% live in urban areas and 3% in settlements and governmental and non-governmental organization camps (6). Data show that nearly one-third (32.7%) of these immigrants live in Tehran Province (2015) and less than half of them (47%) were women (5, 7). Factors such as ethnic or religious wars, unemployment, inflations and low socioeconomic statuses

in Afghanistan are the most important factors for Afghan immigration to Iran. In contrast, factors such as security, geographical proximity, culture, religion and similar language are the most current reasons for the Afghans to migrate to Iran (8). The World Health Organization (WHO) concerns about immigrants' health, nutrition and access to healthy and adequate foods are socially acceptable (9). Despite the large number and long history of Afghan migration to Iran, little is known about their nutritional statuses (10). Therefore, the aim of the present study was to review literatures on food insecurity in Afghans living in Iran.

## Materials and Methods

### Literature search

This review study was carried out on food insecurity prevalence of Afghan refugees in Iran using searches in databases such as Scopus, PubMed, Web of Science, Google Scholar, Scientific Information Database (SID), Noor, Magiran and Irandoc in Persian and English languages (January 2001 to November 2019) and the following search criteria ("Food security"[All Fields] OR "Food insecurity"[All Fields]) AND ("Afghan"[All Fields] OR "migrant"[All Fields] OR "refugee"[All Fields] OR "Iran"[All Fields]).

### Article screening, data extraction and quality assessment

Initial screening was carried out using titles and abstracts. Full texts were downloaded if needed. After searching the articles, they were selected and reviewed by the project executives to remove irrelevant items. Inclusion criteria were assessing food insecurity in Afghan refugees in various regions of Iran. Data extracted from the selected studies included author's name(s), publication year, sampling method and size, food insecurity measurement tools/questionnaires, food security criteria and various degrees of food insecurity.

### Data meta-analysis

In the present study, meta-analysis was carried out only on total food insecurity prevalence in Afghan refugees, because studies have not been reported all degrees of food insecurity (mild, moderate and severe). Data was analyzed using STATA Software v.11.0 (STATA, College Station, TX, USA). Meta-analysis was carried out using random effect model with publication bias and heterogeneity testing with weighting of these studies. Prevalence of food insecurity in Afghan refugees in Iran was estimated at 95% confidence interval (CI).

## Results

In general, four studies were reviewed (8, 11-13); of which, one study was carried out in two provinces of Tehran and Mashhad (12). Table 1 shows characteristics of the studies on food security statuses of Afghan refugees in Iran. The sample size varied 150–414 and household food insecurity access scale (HFIAS), United States Department of Agriculture (USDA) and Radimer/Cornell questionnaires were used as the measurement tools in 2, 1 and 1 studies, respectively. Prevalence of mild, moderate and severe food insecurities was reported as 11.6–16.1, 27.4–46.5 and 20–61%, respectively. The most heterogeneity was found in the prevalence of severe food insecurity. Based on the meta-analysis results from Fig. 1, prevalence of food insecurity in Afghan refugees in Iran was 89% (95% CI: 69–110%). Occupation, education and age of household heads and their wives, monthly incomes, house conditions and welfare facilities of the households were negatively associated to food insecurity. Food insecurity was significantly more prevalent in Afghan immigrants with illegal residential status (8, 12) as well as female-headed and bigger family size households (11-13). Being Sunnis, living in various cities (Tehran and Mashhad) (12) and duration of staying in Iran (12, 13) were associated to food insecurity in Afghan refugees.

Figure 1. Overall prevalence of food insecurity in Afghan refugees in Iran

**Table 1.** Summary of studies on food insecurity of Afghan refugees

No. of study	Authors/year of the study	Setting	Subjects/sampling	Measurement tool(s)	Definition of food insecurity	Food insecurity Prevalence (subgroup) %
1	Abdollahi et al., 2008 (11)	Afghan schools of Pakdasht in the neighborhood of Tehran	414 Afghan households/	USDA food security assessment questionnaire	Food security Mild Moderate Severe	11.2 - 27.4 61
2	Omidvar et al., 2012 (12)	Tehran and Mashhad city	310 Afghan households/ multistage sampling	HFIAS	Food security Mild Moderate Severe	22.9 13.9 42.9 20.3
3	Morshedi and Maarefvand, 2016 (8)	Farahzad and Shahrerey of Tehran city	150 Afghan households/ simple sampling	Radimer-Cornel	Food security Household Adult Child	- 96 93 84.7
4	Pakravan and Mohammadi-Nasrabadi, 2019 (13)	Southern areas of Tehran province	317 Afghan households/ simple random sampling	HFIAS	Food security Mild Moderate Severe	11.3 11.7 40.7 36.3

## Discussion

In the current study, prevalence of food insecurity was estimated 89% in Afghan refugees residing in Iran. A meta-analysis of experiential/perception based studies between 1991 and 2011 in Iran revealed lower rates of moderate (14.9%) and severe (6.0%) FI in Iranian households, respectively (14). However, in a study by Omidvar et al. (15) on data from 2016 Gallup World Poll (GWP), prevalence of moderate and severe FI in Iran and Afghanistan was reported as 47.4 and 39.4%, respectively. Furthermore, prevalence of household food insecurity in Canada was higher in recent immigrant households of less than five years in Canada (10.9%), compared to non-recent immigrant households (7.6%) (16). Food insecurity has gradually decreased over the years, with the prevalence of food insecurity in immigrants reaching nearly the national level after ten years (17-19). Food insecurity, dietary acculturation and inadequate access to healthcare were major contributing factors to newcomer health. Newcomer health decreased over time, which could increase burdens on the Canadian healthcare system. In general, a limited information is available on the relationships between food security and social determinants of health and how these relationships affect unique subgroups of newcomers. Further studies are needed to culturally identify appropriate and cost-effective ways to promote traditional foods and to assess nutritional quality and safety in Canada (20, 21). However, Khakpour et al. (22) reported that food insecurity was a consistent condition for Afghan refugee families in Pakistan regardless of their length of staying.

Data from 2001–2011 Restricted California Health Interview Survey ( $n = 245,679$ ) showed prevalence of food insecurity in white residents (7–9%) and Asian

Americans (5–9%) increased to 11% in 2011 for the two populations. Moreover, food insecurity was higher in illegal immigrants and Asian Americans than white Americans. It was estimated that one in four Latino immigrants and one in five Asian immigrants in California reported food insecurity, even after considering program assistance, English language proficiency and duration of residence (55). Chilton et al. (23) compared risks of household food insecurity and poor health in young children from immigrant ( $n = 7216$ ) and native mothers in US, 1998–2005. Increased risks of fair or poor health and food insecurity were reported in children of recent immigrant households, compared to those in children of US-born mothers ( $p < 0.05$ ). Household food insecurity increased risks of fair or poor child health ( $p < 0.001$ ) and mediated associations between the immigrant status and poor child health. Participations in Food Stamp Program and Special Supplemental Nutrition Program for Women, Infants and Children (WIC) in US-born mothers were respectively higher and lower than that of immigrants. Another study in US by Miller et al. (24) investigated the longitudinal trends of FI in children of immigrants using growth curve modeling and data from 1998 Early Childhood Longitudinal Study-Kindergarten Cohort. The researchers found that children of immigrants included significantly higher initial rates of FI than children of US households. These rates increased significantly over the time; however, rates were slower in next generations. All differences were mediated by poverty. Based on these findings, interventions addressing food insecurity in immigrant households must be carried out to promote child health, considering cultural aspects (25).

Based on cultural food insecurity concept, which is assessed at three levels of food availability, accessibility and use, high costs or variations in tastes of particular foods in every culture may increase food insecurity in immigrants and refugees. Their inability to procure and consume alien foods may damage cultural values regarding food consumption. This can be a potential determinant of cultural identity loss that may affect individual mental health. In addition, cultural food insecurity can determine immigrants' dietary changes to unhealthy diets resulted in non-communicable and nutritional-linked illnesses. Therefore, cultural food insecurity can lead to deteriorating health and well-being of immigrants and refugees (26). Although foods in Canadian urban centers are tailored to various cultures, access to foods through low-processed, healthy favorite ways is difficult. Many immigrants were worried about where and how their foods were prepared. Use of pesticides and fertilizers, availability of Halal products for particular cultures and lack of easy access to organic foods due to their high costs have been major concerns of immigrants and refugees in Canada. Furthermore, it is important that many immigrants do not have the proper knowledge of healthy foods and need financial supports, especially within the first five years of entry, to achieve healthy and adequate foods (26, 27).

Causes of high FI in Afghan immigrant households were not studied in this study. Based on the previous studies on food insecurity in immigrants and refugees, especially Afghans, causes could mostly be attributed to employment in low-level jobs which might lead to low salaries for the head of households and hence low incomes for the families. Stress and anxiety of immigrants and overwhelming efforts to have a normal life with other indigenous families in the country, urge the immigrants to ask jobs that need low skills and wages. In addition, most immigrants enter countries illegally and thus do not receive social and economic protections from the governments. In fact, immigrants are not able to live comfortably because of unfamiliarity with the new environments and sense of unfamiliar identities. Traditional foods and various livelihoods from ethnic-cultural identities custom the nations, which are endangered by the immigration (49). Based on several studies, food insecurity is more prevalent in low-income immigrants, especially in unskilled ones, and is strongly associated to lower consumptions of fruits and vegetables, resulting in lower intakes of micronutrients (2, 24, 28, 29).

### Limitations

To the best of the authors' knowledge, this is the first study reviewing all studies on FI in Afghan refugees in Iran. However, limitations were reported in this study, which might affect results of the review. A major

limitation of the study included the little number of published studies (only four) on FI in Afghan households. Moreover, studies were majorly limited to Tehran Province and only a study on Afghans FI was partially carried out in cities other than Tehran. This made generalizability of the study results difficult in Iran as well as other countries. Low quality and heterogeneity of the studies could be reported as other limitations of the current study.

### Conclusion

Based on the literature reviews, almost 90% of Afghan immigrant households in Iran are food insecure. The high prevalence of food insecurity, especially severe FI, in Afghan refugees in Iran reveals the necessity of legal policies to limit the prevalence of food insecurity in these groups. Furthermore, studies on the underlying causes of food insecurity in Afghan refugees seem necessary. Nutrition and stress management educations for the better food selections, equal job opportunities and modification of legal regulations on using Afghan immigrants in various jobs can be helpful as well.

### Acknowledgement

This review was carried out in National Nutrition and Food Technology Research Institute (NNFTRI), Tehran, Iran. The authors thank the Research Deputy of NNFTRI and all the researchers who helped the current review.

### Financial disclosure

The authors declared no financial interest.
