## I. INTRODUCTION

The goal of this project is to design single-chip low-pass filters with constant group delay in the pass band and 60 dB minimum attenuation in the stop band. The desired 3 dB frequencies are (in Hz ):

$$
2.5,5,10,20,40,80,160,320
$$

A filter class that satisfies the constant delay (linear phase) requirement while providing quite a narrow transition band is the Bessel-Chebyshev filters [1]. It was found that the 7th order Bessel-Chebyshev response satisfied the requirements of the filter. The filter transfer function is

$$
\begin{equation*}
H_{a}(s)=K \frac{\left(s^{2}+8.329^{2}\right)\left(s^{2}+10.57^{2}\right)\left(s^{2}+19.31^{2}\right)}{s^{7}+28 s^{6}+378 s^{5}+3150 s^{4}+17325 s^{3}+62370 s^{2}+135135 s+135135} \tag{1}
\end{equation*}
$$

where $K$ is a normalization constant so that $H(0)=1$. The 3 dB frequency (normalized) is at $\Omega=$ 2.286. The denominator is the 7th order Bessel polynomial. The magnitude and phase plots of $H_{a}(j \Omega)$ are shown in figure 1.

Figure 1. Loss and group delay of the 7th order Bessel-Chebyshev filter

The implementation was as a switched-capacitor (SC) network. These are sampled data systems, but the signal amplitude is not quantized [2]. The SC technique allows high order filters to be integrated on silicon with very good accuracy. The shape of the transfer function depends on the capacitor ratios which are quite precisely controlled. The frequency axis can be scaled by changing the system clock frequency.

## II. CASCADE SYNTHESIS

The transfer function in equation (1) can be expressed as the product of lower order functions of $s$, namely bilinear and biquadratic functions. The desired transfer function is obtained when circuits realizing these simpler functions are cascaded. The rest of this section describes the design steps.

## A. Factorization of the transfer function:

The numerator of (1) is already factorized, the denominator can be factorized using the Newton-Raphson root-finding algorithm. The poles and zeros of (1) are given below:

$$
\begin{array}{ll}
p_{0}=-4.9717869 & \\
p_{1}=-2.6856769+\mathrm{j} 5.4206941 & p_{4}=-2.6856769-\mathrm{j} 5.4206941 \\
p_{2}=-4.0701392+\mathrm{j} 3.5171760 & p_{5}=-4.0701392-\mathrm{j} 3.5171760 \\
p_{3}=-4.7582905+\mathrm{j} 1.7392861 & p_{6}=-4.7582905-\mathrm{j} 1.7392861 \\
z_{0}=\infty & z_{4}=-\mathrm{j} 8.329 \\
z_{1}=\mathrm{j} 8.329 & z_{5}=-\mathrm{j} 10.57 \\
z_{2}=\mathrm{j} 10.57 & z_{6}=-\mathrm{j} 19.31 \\
z_{3}=\mathrm{j} 19.31 &
\end{array}
$$

Therefore, the transfer function can be decomposed into one bilinear and three biquadratic functions.

## B. Pairing of poles and zeros:

After we pair $z$, and $p$, to form the bilinear factor, there remains the issue of pairing the remaining three complex conjugate pairs of poles with the three complex conjugate pairs of zeros.

Out of the many possible pairings of poles and zeros some result in transfer functions that are less sensitive to element nonidealities of the actual circuit implementation. It is known that the magnitude of a bounded transfer function is not sensitive to element variations at the frequencies where it achieves its maximum [3]. Motivated by this property, we can define our objective in the pairing of poles and zeros as that the magnitude of the transfer function of each of the building blocks must be as flat as possible in the pass band of the filter [4].

The flattest blocks occur when the pole-zero pairs are $\left(p_{1}, z_{1}\right),\left(p_{2}, z_{2}\right),\left(p_{3}, z_{3}\right)$. The $Q$ factors of each block (pole) are as follows:

$$
\begin{aligned}
& Q_{1}=1.126,\left(p_{1}\right) \\
& Q_{2}=0.661,\left(p_{2}\right) \\
& Q_{3}=0.532,\left(p_{3}\right)
\end{aligned}
$$

## C. Ordering of the blocks:

As it is with the pairing of poles and zeros, different orderings of the blocks result in different sensitivities to the nonidealities in the implementation. The objective is again to have the flattest possible response in the pass band at the output of the each block. It turns out that the best ordering is $\left(p_{0}, z_{0}\right) \rightarrow\left(p_{1}, z_{1}\right) \rightarrow\left(p_{2}, z_{2}\right) \rightarrow\left(p_{3}, z_{3}\right)$. Let us define the transfer functions for each block:

$$
\begin{gather*}
H_{0 a}(s)=k_{0} \frac{1}{s+4.9717869}  \tag{2}\\
H_{1 a}(s)=k_{1} \frac{\left(s^{2}+8.329^{2}\right)}{\left(s^{2}+5.3713538 s+36.5967852\right)}  \tag{3}\\
H_{2 a}(s)=k_{2} \frac{\left(s^{2}+10.57^{2}\right)}{\left(s^{2}+8.1402784 s+28.9365601\right)}  \tag{4}\\
H_{3 a}(s)=k_{3} \frac{\left(s^{2}+19.31^{2}\right)}{\left(s^{2}+9.5165906 s+25.6664902\right)} \tag{5}
\end{gather*}
$$

## D. Mapping to the discrete time domain:

We have dealt with the continuous-time frequency transfer function until now. We use the bilinear mapping to the discrete-time complex frequency, $z$, domain:

$$
\begin{equation*}
s=\frac{2}{T} \frac{z-1}{z+1} \tag{6}
\end{equation*}
$$

where $T$ is the sampling period and the continuous- and discrete-time complex frequencies are respectively,

$$
\begin{gathered}
s=\Sigma+j \Omega \\
z=r e^{j \omega T}
\end{gathered}
$$

From (6) we obtain

$$
\begin{equation*}
\omega T / 2=\arctan (\Omega T / 2) \tag{7}
\end{equation*}
$$

If $\Omega T$ is very small then the relationship between $\omega$ and $\Omega$ is almost linear.

Applying (6) to (2) through (5) gives the transfer functions to be realized. The numerical values
depend on the particular value of $T$.

## E. Filter sections:

We realized the filter as a cascade of one bilinear and three biquadratic sections.

The circuit diagram of the bilinear filter section is shown in figure 2.

Figure 2. The bilinear SC section.
The transfer function in terms of the capacitor values is given below ( $C_{A}$ is set to 1 ):

$$
\begin{equation*}
H_{0}(z)=-\frac{C_{1} z+\left(C_{3}-C_{1}\right)}{\left(1+C_{2}\right) z-1} \tag{8}
\end{equation*}
$$

The circuit diagram of the high- $Q$ biquadratric filter section is shown in figure 3.

Figure 3. The high- $Q$ biquadratic $S C$ section.
The transfer function in terms of the capacitor values is given below ( $C_{A}$ and $C_{B}$ are set to 1 ):

$$
\begin{equation*}
H_{1}(z)=-\frac{C_{5} z^{2}+\left(C_{1} C_{3}+-2 C_{5}\right) z+C_{5}}{z^{2}+\left(C_{2} C_{3}+C_{3} C_{4}-2\right) z+\left(1-C_{3} C_{4}\right)} \tag{9}
\end{equation*}
$$

The circuit diagram of the low- $Q$ biquadratric filter sections is shown in figure 4.

Figure 4. The low- $Q$ biquadratic $S C$ section.

The transfer function in terms of the capacitor values is given below ( $C_{A}$ and $C_{B}$ are set to 1 ):

$$
\begin{equation*}
H_{2,3}(z)=-\frac{C_{5} z^{2}+\left(C_{1} C_{3}+-2 C_{5}\right) z+C_{5}}{\left(1+C_{4}\right) z^{2}+\left(C_{2} C_{3}-C_{4}-2\right) z+1} \tag{10}
\end{equation*}
$$

The calculated capacitor values are such that when the clock frequency ( $1 / T$ ) is 10 kHz , the 3 dB frquency is 40 Hz . The capacitors are also scaled for maximum dynamic range and minimum size. The resulting values are shown in Table 1.

TABLE 1
Capacitor values for $\mathbf{3 d B}$ frequency at 40 Hz with 10 kHz clock

|  | Capacitor | Value (in unit capacitors) |
| :--- | :---: | :---: |
| Bilinear Section | $C_{A}$ | 35.58923 |

|  | $C_{5}$ | 1.0 |

## E. Filter sections with reduced capacitor spread:

A second filter was designed to realize much lower passband edge frequencies with moderate clock speeds. We used capacitive voltage dividers to reduce the capacitor spread to realizable levels. The filter has 3 dB loss at 2.5 Hz when operated with 10 kHz clock.

The circuit diagrams for the filter sections with capacitive voltage dividers ( $T$-sections) are shown in Figures 5 through 7.

Figure 5. Bilinear section with voltage dividers.

Figure 6. High- $Q$ biquadratic section with voltage dividers.

Figure 7. Low- $Q$ biquadratic section with voltage dividers.

The capacitor values are given in Table 2.

TABLE 2
Capacitor values for $\mathbf{3 ~ d B}$ frequency at 2.5 Hz with 10 kHz clock

|  | Capacitor | Value with $T$ | Value without $T$ |
| :---: | :---: | :---: | :---: |

|  | $C_{1 S}$ | 1.0 |  |
|  | $C_{1 T}$ | 19.25835 |  |
|  | $C_{2}$ | 1.02497 | 1.0 |
|  | $\mathrm{C}_{2 S}$ | 1.02497 |  |
|  | $C_{2 T}$ | 19.25835 |  |
|  | $C_{3}$ | 1.0 | 1.0 |
|  | $C_{3 S}$ | 12.0 |  |
|  | $C_{3 T}$ | 19.25835 |  |
|  | $\mathrm{C}_{4}$ | 1.02497 | 1.0 |
|  | $C_{5}$ | 2.17828 | 46.30406 |

## 2nd Low-Q Biquadratic Section

| $C_{A}$ | 26.28833 | 539.59912 |
| :--- | :---: | :---: |
| $C_{B}$ | 14.85170 | 152.42438 |
| $C_{1}$ | 1.18146 | 1.0 |
| $C_{1 S}$ | 1.18146 |  |
| $C_{1 T}$ | 26.28833 |  |
| $C_{2}$ | 1.0 | 1.0 |
| $C_{2 S}$ | 1.5 |  |
| $C_{2 T}$ | 26.28833 |  |
| $C_{3}$ | 1.70085 | 1.0 |
| $C_{3 S}$ | 1.70085 |  |
| $C_{3 T}$ | 26.28833 |  |
| $C_{4}$ | 2.0 | 1.0 |
| $C_{5}$ | 1.02569 | 10.52675 |

As can be seen from Table 2, the overall capacitor area is reduced by a power of 2.

## III. FABRICATION AND TEST RESULTS

Both of the designs were fabricated as a single chip using $5-\mu \mathrm{m}$ double-poly CMOS process provided by MOSIS, a federal government supproted agency. We obtained the samples in March 1988. Table 3 gives some of the physical properties of the fabricated chips:

TABLE 3
Some Physical Properties of the Fabricated Filter

| Technology: | p-well CMOS, double poly |
| :--- | :--- |
| Minimum feature size: | $5 \mu \mathrm{~m}$ |
| Chip size: | $6800 \mu \mathrm{~m} \times 4595 \mu \mathrm{~m}$ |
|  | $(265 \mathrm{mil} \times 179 \mathrm{mil})$ |
| Unit capacitor: | 0.978 pF |
| Power supplies: | $\pm 5 \mathrm{~V}$ |
| Power consumption: | 280 mW |
| Clock input: | $\pm 5 \mathrm{~V}$ square-wave with $50 \%$ duty cycle |
| Package: | 40 pin ceramic DIP |

The chip phograph is shown in Figure 8.

The yield was somewhat low, around $50 \%$. This could have been due to the large size of the chip by typical MOSIS standards. The frequency domain measurments were done using a network analyzer. The magnitude and phase response plots are provided at the end of the section. The
results for both sets of filters are in close agreement with the design values. Due to the limitations of the network analyzer the plots do not show the response in the 0 to 5 Hz range. Because of this limitation, the plots for the filter with the voltage dividers were obtained with 160 kHz clock frequency.

The manual testing at DC showed that the filter with voltage dividers had quite high output offset voltage, around 0.8 V . But the other filter had much lower output offset, around 20 mV . We have found that the offset voltage can be reduced by adjusting the rising and falling times of the input clock signal.

The filter that was designed to give 40 Hz passband edge at 10 kHz clock operated without problems for clock frequencies in the range 625 Hz to 100 KHz .
