# APPROXIMATION ORDER FROM CERTAIN SPACES OF SMOOTH BIVARIATE SPLINES ON A THREE-DIRECTION MESH ${ }^{1}$ 

RONG-QING JIA

#### Abstract

Let $\Delta$ be the mesh in the plane obtained from a uniform square mesh by drawing in the north-east diagonal in each square. Let $\pi_{k, \Delta}^{\rho}$ be the space of bivariate piecewise polynomial functions in $C^{\rho}$, of total degree $\leq k$, on the mesh $\Delta$. Let $m(k, \rho)$ denote the approximation order of $\pi_{k, \Delta}^{\rho}$. In this paper, an upper bound for $m(k, \rho)$ is given. In the space $3 \leq 2 k-3 \rho \leq 7$, the exact values of $m(k, \rho)$ are obtained:

$$
\begin{aligned}
& m(k, \rho)=2 k-2 \rho-1 \\
& m(k, \rho)=2 k-2 \rho-2
\end{aligned} \text { for } 2 k-3 \rho=3 \text { or } 4, ~ 子-3 \rho=5,6 \text { or } 7 .
$$

In particular, this result answers negatively a conjecture of de Boor and Höllig.

1. Introduction. In this paper we study the approximation order from certain spaces of smooth bivariate splines on a three-dimension mesh. The work in this respect has been initiated by de Boor and DeVore [BD], and de Boor and Höllig $\left[\mathbf{B H}_{1}-\mathbf{B H}_{3}\right]$. Here we follow them and introduce some notation. Let

$$
\Delta:=\bigcup_{n \in Z}\left\{\left(x_{1}, x_{2}\right) \in R^{2} ; x_{1}=n, x_{2}=n \text { or } x_{2}-x_{1}=n\right\}
$$

Namely, the mesh $\Delta$ is obtained from a uniform square mesh by drawing in the north-east diagonal in each square. Let

$$
S:=\pi_{k, \Delta}^{\rho}:=\pi_{k, \Delta} \cap C^{\rho}
$$

be the space of bivariate pp (piecewise polynomial) functions in $C^{\rho}$, of total degree $\leq k$, on the mesh $\Delta$. The approximation order of $S$ is, by definition, the integer $m$ for which the following holds: For any $f \in C^{m}$,

$$
\operatorname{dist}\left(f, S_{h}\right) \leq(\text { const }) h^{m}|f|_{m, \infty},
$$

while, for some $C^{m+1}$-function $f$ with $\|f\|_{m+1, \infty}<\infty$,

$$
\operatorname{dist}\left(f, S_{h}\right) \neq o\left(h^{m}\right)
$$

Here the scale $\left(S_{h}\right)$ of approximating spaces is generated from $S$ by simple scaling:

$$
S_{h}:=\sigma_{h}(S)
$$

with

$$
\left(\sigma_{h} f\right)(x):=f(x / h), \quad \text { all } f, x, h
$$

[^0]Further,

$$
\operatorname{dist}(f, S):=\inf _{s \in S}\|f-s\|
$$

and $\|\cdot\|$ is the sup norm on $\mathbf{R}^{2}$ :

$$
\|f\|:=\|f\|_{\infty}:=\sup _{x \in R^{2}}|f(x)| .
$$

Moreover,

$$
|f|_{m, \infty}:=\sum_{|\alpha|=m}\left\|D^{\alpha} f\right\|, \quad\|f\|_{m, \infty}:=\sum_{|\alpha| \leq m}\left\|D^{\alpha} f\right\| .
$$

We denote by $m(k, \rho)$ the approximation order of $\pi_{k, \Delta}^{\rho}$.
Only a few results about $m(k, \rho)$ are known:

$$
\begin{gathered}
m(k, \rho)= \begin{cases}k+1 & \text { for } k \geq 4 \rho+1(\text { see }[\mathbf{B Z}]), \\
0 & \text { for } 2 k-3 \rho \leq 1(\text { see }[\mathbf{B D}]), \\
2 k-2 \rho & \text { for } 2 k-3 \rho=2(\text { see }[\mathbf{B H} \mathbf{1}]), \\
m(3,1)=3 \quad\left(\text { see }\left[\mathbf{B H}_{\mathbf{2}}\right]\right)\end{cases}
\end{gathered}
$$

An upper bound for $m(k, \rho)$ has been obtained by de Boor and Höllig (see $\left[\mathbf{B H}_{\mathbf{3}}\right.$, Theorem 3]):

$$
m(k, \rho) \leq \min \{2(k-\rho), k+1\} .
$$

Also, they raised the following
CONJECTURE. $m(k, \rho) \geq \min \{2(k-\rho), k+1\}-1$.
By using a quasi-interpolant scheme, $[\mathbf{J}]$ gives

$$
\begin{equation*}
m(k, \rho) \geq \min \{2(k-\rho), k+1\}-2 \tag{1}
\end{equation*}
$$

A question naturally arises: Can the lower bound given by (1) be improved? This paper shows that this lower bound is sharp. More precisely, we will prove the following results:

$$
\begin{equation*}
m(k, \rho)=2 k-2 \rho-1 \quad \text { for } 2 k-3 \rho=3 \text { or } 4 \tag{2}
\end{equation*}
$$

$$
\begin{equation*}
m(k, \rho)=2 k-2 \rho-2 \text { for } 2 k-3 \rho=5,6 \text { or } 7 . \tag{3}
\end{equation*}
$$

In particular,

$$
m(k, \rho)=\min \{2(k-\rho), k+1\}-2 \text { for } 2 k-3 \rho=5,6 \text { or } 7 \text { and } k \leq 2 \rho+1 .
$$

This answers negatively the conjecture of de Boor and Höllig.
Here is an outline of this paper. $\S \S 2-4$ treat the algebra generated by the shift operators, the box splines and the jump operators, respectively. Those three sections are tools, and they prepare for the core of this paper, §5, which reduces the approximation problem to a determinant problem and hence gives an upper bound for the approximation order. In $\S 6$, the result of $\S 5$ is applied to obtain (2) and (3).

Before proceeding with the proofs of (2) and (3), we need to introduce more notation. For a set $E$, we denote by $|E|$ the cardinality of $E$. Let $\mathbf{Z}_{+}$be the set of nonnegative integers. Let $e_{1}, e_{2}$ be the unit coordinate vectors in the plane; i.e.,

$$
e_{1}=(1,0) \quad e_{2}=(0,1)
$$

As usual, $D_{i}$ denotes the derivative with respect to the $i$ th argument $(i=1,2)$. Let

$$
e_{3}=e_{1}+e_{2} \quad \text { and } \quad D_{3}=D_{1}+D_{2}
$$

For a bivariate function $f: \mathbf{R}^{2} \rightarrow \mathbf{R}$ and a real number $a$, the difference operators $\nabla_{r, a}$ are given by

$$
\nabla_{r, a} f:=f-f\left(\cdot-a e_{r}\right) \quad(r=1,2,3) .
$$

If $a=1, \nabla_{r, a}$ is abbreviated to $\nabla_{r}$. Let $\pi$ be the space of all bivariate polynomials, $\pi_{k}$ the space of all bivariate polynomials of total degree $\leq k$. For a polynomial $p$, its degree is denoted by $\operatorname{deg} p$.
2. The algebra generated by the shift operators. A mapping from $\mathbf{Z}^{\mathbf{2}}$ to $\mathbf{R}$ is called a bivariate sequence. The set of all the bivariate sequences equipped with addition and scalar multiplication forms a linear space, which we denote by $l\left(\mathbf{Z}^{2}\right)$. All the linear operators on $l\left(\mathbf{Z}^{2}\right)$ form a noncommutative algebra. We want to consider one of its subalgebras. Let $T_{r}$ be the shift operators given by

$$
T_{r} g:=g\left(\cdot-e_{r}\right), \quad \text { all } g \in l\left(\mathbf{Z}^{2}\right)(r=1,2,3)
$$

Clearly

$$
T_{3}=T_{2} T_{1}=T_{1} T_{2}
$$

Let $A$ be the subalgebra generated by $T_{1}, T_{1}^{-1}, T_{2}$ and $T_{2}^{-1}$. Then $A$ is commutative. Let $I$ be the identity operator on $l\left(\mathbf{Z}^{2}\right)$. Then the difference operators can be represented as

$$
\nabla_{r}=I-T_{r} \quad(r=1,2,3)
$$

In particular,

$$
\begin{aligned}
\nabla_{3} & =I-T_{3}=I-T_{1} T_{2} \\
& =I-\left(I-\nabla_{1}\right)\left(I-\nabla_{2}\right)=\nabla_{1}+\nabla_{2}-\nabla_{1} \nabla_{2}
\end{aligned}
$$

If we impose a sup norm on $l\left(\mathbf{Z}^{2}\right)$, then we get the normed linear space $l_{\infty}\left(\mathbf{Z}^{2}\right)$. Thus we can talk about the norm of an operator on $l_{\infty}\left(\mathbf{Z}^{2}\right)$ in the usual sense. Moreover, we can talk about positive operators. A sequence $g \in l\left(\mathbf{Z}^{2}\right)$ is called positive, and denoted by $g \geq 0$, if

$$
g(j) \geq 0 \quad \text { for any } j \in \mathbf{Z}^{2} .
$$

An operator $L$ is called positive if

$$
L g \geq 0 \quad \text { whenever } g \geq 0
$$

A sequence $g \in l\left(\mathbf{Z}^{2}\right)$ is called constant if there exists a real number $b$ such that

$$
g(j)=b \quad \text { for any } j \in \mathbf{Z}^{2}
$$

We denote by 1 the constant sequence which takes value 1 . If $L$ is a positive operator on $l\left(\mathbf{Z}^{2}\right)$, then we have $\|L\|=\|L \mathbf{1}\|$. Indeed, since $-\|g\| \mathbf{1} \leq g \leq\|g\| \mathbf{1}$, we have

$$
-\|g\|(L \mathbf{1}) \leq L g \leq\|g\|(L \mathbf{1})
$$

and so

$$
\|L g\| \leq\|g\|\|L \mathbf{1}\| .
$$

This shows that $\|L\| \leq\|L 1\|$. The other direction holds because $\|1\|=1$. To give an example of positive operators, we consider

$$
\begin{equation*}
H_{r}:=\sum_{t=0}^{N-1} T_{r}^{t} \quad(r=1,2,3) \tag{4}
\end{equation*}
$$

where $N$ is a positive integer. Then $H_{r} \mathbf{1}=N$; hence

$$
\left\|H_{r}\right\|=N \quad \text { for } r=1,2,3
$$

3. Box splines. Box splines were introduced in [BD and $\left.\mathbf{B H}_{\mathbf{1}}\right]$ and have proved useful in approximation problems. The key point is that the approximation order of $S$ is determined by all the box splines contained in $S$ (see $\left.\left[\mathbf{B H}_{\mathbf{3}}\right]\right)$. Here we specify the definition of box splines from $\left[\mathbf{B H}_{\mathbf{1}}\right]$ to suit our discussion. For $\lambda=\left(\lambda_{1}, \lambda_{2}, \lambda_{3}\right) \in \mathbf{Z}_{+}^{3}$ with $|\lambda|=\lambda_{1}+\lambda_{2}+\lambda_{3}$ as usual, let $\Xi=\left(\xi_{i}\right)_{1}^{|\lambda|}$ be the sequence given by

$$
\xi_{1}=\cdots=\xi_{\lambda_{1}}=e_{1}, \quad \xi_{\lambda_{1}+1}=\cdots=\xi_{\lambda_{1}+\lambda_{2}}=e_{2}, \quad \xi_{\lambda_{1}+\lambda_{2}+1}=\cdots=\xi_{|\lambda|}=e_{3}
$$

Then the box spline $M_{\lambda}:=M_{\Xi}$ is defined as the distribution given by the rule

$$
M_{\Xi}: \phi \rightarrow \int \phi\left(\sum_{i=1}^{|\lambda|} u(i) \xi_{i}\right) d u
$$

where the integral is taken over the cube $[0,1]^{|\lambda|}$. Let

$$
d:=|\lambda|-\max \left\{\lambda_{r}\right\}-1
$$

Then $M_{\lambda} \subset L_{\infty}^{(d)} \cap C^{(d-1)}$. In addition, $d$ is the largest integer such that this relation is true. In particular, a box spline $M_{\lambda}$ belongs to $L_{\infty}$ if and only if $|\lambda|-\max \left\{\lambda_{r}\right\} \geq$ 1. In what follows, all the box splines are assumed to be in $L_{\infty}$.

A box spline series has the following nice property with respect to derivatives:

$$
D_{i}\left(\sum_{j \in Z^{2}} a(j) M_{\Xi}(\cdot-j)\right)=\sum_{j \in Z^{2}}\left(\nabla_{i} a\right)(j) M_{\Xi \backslash e_{i}}(\cdot-j), \quad \text { if } e_{i} \in \Xi .
$$

Let $S_{\lambda}:=$ the linear span of $M_{\lambda}(\cdot-j), j \in Z^{2}$; that is,

$$
S_{\lambda}:=\left\{\sum a(j) M_{\lambda}(\cdot-j) ; a \in l\left(Z^{2}\right)\right\}
$$

LEMMA 1. The following inclusion relations hold:

$$
\begin{array}{ll}
S_{\lambda_{1}, \lambda_{2}, \lambda_{3}} \subset S_{\lambda_{1}+1, \lambda_{2}, \lambda_{3}-1}+S_{\lambda_{1}+1, \lambda_{2}-1, \lambda_{3}} & \text { if } \min \left\{\lambda_{2}, \lambda_{3}\right\} \geq 1 \\
S_{\lambda_{1}, \lambda_{2}, \lambda_{3}} \subset S_{\lambda_{1}, \lambda_{2}+1, \lambda_{3}-1}+S_{\lambda_{1}-1, \lambda_{2}+1, \lambda_{3}} & \text { if } \min \left\{\lambda_{3}, \lambda_{1}\right\} \geq 1 \\
S_{\lambda_{1}, \lambda_{2}, \lambda_{3}} \subset S_{\lambda_{1}-1, \lambda_{2}, \lambda_{3}+1}+S_{\lambda_{1}, \lambda_{2}-1, \lambda_{3}+1} & \text { if } \min \left\{\lambda_{1}, \lambda_{2}\right\} \geq 1
\end{array}
$$

Proof. We need only prove ( $1^{\circ}$ ). Any $s \in S_{\lambda}$ can be expressed as a series $\sum a(j) M_{\lambda}(\cdot-j)$. Set, for $j=\left(j_{1}, j_{2}\right) \in Z^{2}$,

$$
b\left(j_{1}, j_{2}\right):= \begin{cases}a\left(0, j_{2}\right)+\cdots+a\left(j_{1}, j_{2}\right) & \text { for } j_{1} \geq 0 \\ 0 & \text { for } j_{1}=-1 \\ -a\left(-1, j_{2}\right)-\cdots-a\left(j_{1}+1, j_{2}\right) & \text { for } j_{1}<-1\end{cases}
$$

Then $\nabla_{1} b=a$; hence

$$
\begin{aligned}
s & =\sum\left(\nabla_{1} b\right)(j) M_{\lambda}(\cdot-j)=D_{1}\left(\sum b(j) M_{\lambda_{1}+1, \lambda_{2}, \lambda_{3}}(\cdot-j)\right) \\
& =\left(D_{3}-D_{2}\right)\left(\sum b(j) M_{\lambda_{1}+1, \lambda_{2}, \lambda_{3}}(\cdot-j)\right) \\
& =\sum\left(\nabla_{3} b\right)(j) M_{\lambda_{1}+1, \lambda_{2}, \lambda_{3}-1}(\cdot-j)-\sum\left(\nabla_{2} b\right)(j) M_{\lambda_{1}+1, \lambda_{2}-1, \lambda_{3}}(\cdot-j) .
\end{aligned}
$$

This shows that

$$
s \in S_{\lambda_{1}+1, \lambda_{2}, \lambda_{3}-1}+S_{\lambda_{1}+1, \lambda_{2}-1, \lambda_{3}} .
$$

The proof of Lemma 1 is complete.
4. Jump operators. We denote by $\mathbf{S}_{\Delta}$ the space of all splines (piecewise polynomials) on the mesh $\Delta$. For $s \in \mathbf{S}_{\Delta}$, we think of $s$ as defined on $\mathbf{R}^{2} \backslash \Delta$. To describe the jump of a given spline $s$ in the direction $e_{r}(r=1,2,3)$, we introduce the jump operators $J_{r}$ as follows:

$$
J_{r} s:=\lim _{\varepsilon \rightarrow+0}\left[s\left(\cdot+\varepsilon e_{r}\right)-s\left(\cdot-\varepsilon e_{r}\right)\right] .
$$

On each component of $\mathbf{R}^{2} \backslash \Delta, s$ is a polynomial; hence the above limit always exists. Clearly, if $s$ is continuous at $x$, then $J_{r} s(x)=0$ for all $r=1,2,3$. Thus the support of $J_{r} s$ is included in $\Delta$. Since we think of $s$ as defined on $\mathbf{R}^{2} \backslash \Delta, J_{r} s$ is thought of as defined on $\Delta \backslash \mathbf{Z}^{2}$. The operators $J_{r}$ are linear and bounded: $\left\|J_{r}\right\| \leq 2$.

If $g$ is defined on $\Delta \backslash \mathbf{Z}^{2}$, and if $g$ is a polynomial in each component of $\Delta \backslash \mathbf{Z}^{2}$, then we can define

$$
K_{r} g(j):=\lim _{\delta \rightarrow+0} g\left(j+\delta e_{r}\right), \quad j \in Z^{2}, r=1,2,3
$$

The operators $K_{r}$ given by the above are linear and bounded: $\left\|K_{r}\right\| \leq 1$.
We also want to give a description for the jump of the derivatives of a given spline. To this end we introduce the operators $R_{r, n}$ on $l\left(\mathbf{Z}^{2}\right)$ given by the rule

$$
R_{r, n} a:=\sum_{t=0}^{n} a\left(\cdot-t e_{r}\right) M_{n}(t), \quad r=1,2,3 ; n \geq 1
$$

(Recall that $M_{n}$ is the univariate $B$-spline with support [ $0, n$ ] on the uniform mesh Z.) When $n<1$, we interpret $R_{r, n}$ as zero. Since $\sum_{t=0}^{n} M_{n}(t)=1$, the operator $R_{r, n}$ is bounded by 1 .

We make some convention about the combination notation $\binom{m}{n}$. Whatever $m$ and $n$ might be, we agree that

$$
\binom{m}{n}= \begin{cases}1 & \text { if } m=n \\ 0 & \text { if } m<n\end{cases}
$$

Now we are ready to state the main result of this section.
LEMMA 2. The following formulae hold:

$$
\begin{align*}
& K_{1} J_{2} D_{2}^{k-1}\left(\sum a(j) M_{\lambda}(\cdot-j)\right) \\
& \quad=R_{1,|\lambda|-k}\binom{k-\lambda_{2}-1}{\lambda_{3}-1}\left(-\nabla_{1}\right)^{k-\left(\lambda_{2}+\lambda_{3}\right)} \nabla_{2}^{\lambda_{2}} \nabla_{3}^{\lambda_{3}} a \\
& K_{2} J_{3} D_{3}^{k-1}\left(\sum a(j) M_{\lambda}(\cdot-j)\right) \\
& \quad=R_{2,|\lambda|-k}\binom{k-\lambda_{3}-1}{\lambda_{1}-1} \nabla_{1}^{\lambda_{1}} \nabla_{2}^{k-\left(\lambda_{3}+\lambda_{1}\right)} \nabla_{3}^{\lambda_{3}} a \\
& K_{3} J_{1} D_{1}^{K-1}\left(\sum a(j) M_{\lambda}(\cdot-j)\right) \\
& \quad=R_{3,|\lambda|-k}\binom{k-\lambda_{1}-1}{\lambda_{2}-1} \nabla_{1}^{\lambda_{1}}\left(-\nabla_{2}\right)^{\lambda_{2}} \nabla_{3}^{k-\left(\lambda_{1}+\lambda_{2}\right)} a .
\end{align*}
$$

Proof. We need only prove $\left(1^{\circ}\right)$, because $\left(2^{\circ}\right)$ and $\left(3^{\circ}\right)$ can be proved in a similar way. For simplicity, write

$$
s=\sum a(j) M_{\lambda}(\cdot-j)
$$

The proof of $\left(1^{\circ}\right)$ will go case by case.
Case 1. $k \leq \lambda_{2}-1$.
In this case,

$$
D_{2}^{k-1} s=\sum\left(\nabla_{2}^{k-1} a\right)(j) M_{\lambda_{1}, \lambda_{2}-k+1, \lambda_{3}}(\cdot-j)
$$

Since $\lambda_{2}-k+1 \geq 2, M_{\lambda_{1}, \lambda_{2}-k+1, \lambda_{3}}$ is continuous in the $e_{2}$ direction. This shows that $J_{2} D_{2}^{k-1} s=0$. On the other hand, $k-\lambda_{2}-1<\lambda_{3}-1$; hence the right-hand side of $\left(1^{\circ}\right)$ is also zero in this case.

Case 2. $k=\lambda_{2}$.
This case is divided into three subcases.
Subcase 1. $\min \left\{\lambda_{1}, \lambda_{3}\right\} \geq 1$.
In this case,

$$
D_{2}^{k-1} s=\sum\left(\nabla_{2}^{k-1} a\right)(j) M_{\lambda_{1}, 1, \lambda_{3}}(\cdot-j)
$$

Since $M_{\lambda_{1}, 1, \lambda_{3}} \in C\left(R^{2}\right)$, we obtain the desired conclusion.
Subcase 2. $\lambda_{1}=0, \lambda_{3} \geq 1$.
In this case, $M_{\lambda}$ is continuous in the $e_{2}$ direction at the points $j+\delta e_{1}, j \in \mathbf{Z}^{2}$, $0<\delta<1$; hence $K_{1} J_{2} D_{2}^{k-1} s=0$, while the right-hand side of ( $1^{\circ}$ ) is also zero, because $k-\lambda_{2}-1<\lambda_{3}-1$.

Subcase 3. $\lambda_{1} \geq 1, \lambda_{3}=0$.
In this case

$$
D_{2}^{k-1} s=\sum\left(\nabla_{2}^{k-1} a\right)(j) M_{\lambda_{1}, 1,0}(\cdot-j)
$$

We have

$$
M_{\lambda_{1}, 1,0}\left(x_{1}, x_{2}\right)=M_{\lambda_{1}}\left(x_{1}\right) M_{1}\left(x_{2}\right)
$$

It follows that, for $i=\left(i_{1}, i_{2}\right) \in Z^{2}$ and $0<\delta<1$,

$$
J_{2} M_{\lambda_{1}, 1,0}\left(i+\delta e_{1}\right)= \begin{cases}M_{\lambda_{1}}\left(i_{1}+\delta\right) & \text { if } i_{2}=0 \\ -M_{\lambda_{1}}\left(i_{1}+\delta\right) & \text { if } i_{2}=1 \\ 0 & \text { otherwise }\end{cases}
$$

Therefore

$$
\begin{aligned}
& \left(K_{1} J_{2} D_{2}^{k-1} s\right)(i) \\
& \quad=\sum_{j_{1} \in Z}\left[\left(\nabla_{2}^{k-1} a\right)\left(j_{1}, i_{2}\right) M_{\lambda_{1}}\left(i_{1}-j_{1}\right)-\left(\nabla_{2}^{k-1} a\right)\left(j_{1}, i_{2}-1\right) M_{\lambda_{1}}\left(i_{1}-j_{1}\right)\right] \\
& \quad=\sum_{j_{1} \in Z}\left(\nabla_{2}^{k} a\right)\left(j_{1}, i_{2}\right) M_{\lambda_{1}}\left(i_{1}-j_{1}\right) \\
& \quad=\sum_{t=0}^{\lambda_{1}}\left(\nabla_{2}^{k} a\right)\left(i_{1}-t, i_{2}\right) M_{\lambda_{1}}(t) \\
& \quad=R_{1,|\lambda|-k} \nabla_{2}^{\lambda_{2}} a(i)
\end{aligned}
$$

This proves $\left(1^{\circ}\right)$ in this case, since $k-\lambda_{2}-1=-1=\lambda_{3}-1$ and $k-\left(\lambda_{2}+\lambda_{3}\right)=0$.

Case 3. $k>\lambda_{2}$.
In this case,

$$
D_{2}^{k-1} s=D_{2}^{k-1-\lambda_{2}}\left(\sum\left(\nabla_{2}^{\lambda_{2}} a\right)(j) M_{\lambda_{1}, 0, \lambda_{3}}(\cdot-j)\right)
$$

By the binomial theorem, we have

$$
D_{2}^{k-1-\lambda_{2}}=\left(D_{3}-D_{1}\right)^{k-1-\lambda_{2}}=\sum_{p=0}^{k-1-\lambda_{2}}\binom{k-1-\lambda_{2}}{p} D_{3}^{p}\left(-D_{1}\right)^{k-1-\lambda_{2}-p}
$$

If $p \geq \lambda_{3}$ or $k-1-\lambda_{2}-p \geq \lambda_{1}$, then

$$
D_{3}^{p}\left(-D_{1}\right)^{k-1-\lambda_{2}-p} M_{\lambda_{1}, 0, \lambda_{3}}(x)=0 \quad \text { for } x \notin \Delta ;
$$

hence

$$
J_{2}\left(D_{3}^{p}\left(-D_{1}\right)^{k-1-\lambda_{2}-p} M_{\lambda_{1}, 0, \lambda_{3}}\right)=0 .
$$

Assume $p<\lambda_{3}$ and $k-1-\lambda_{2}-p<\lambda_{1}$. Then

$$
\begin{aligned}
D_{3}^{p}(- & \left.D_{1}\right)^{k-1-\lambda_{2}-p}\left(\sum_{j}\left(\nabla_{2}^{\lambda_{2}} a\right)(j) M_{\lambda_{1}, 0, \lambda_{3}}(\cdot-j)\right) \\
& =\sum_{j}\left(\left(-\nabla_{1}\right)^{k-1-\lambda_{2}-p} \nabla_{2}^{\lambda_{2}} \nabla_{3}^{p} a\right)(j) M_{\lambda_{1}+\lambda_{2}+p+1-k, 0, \lambda_{3}-p}(\cdot-j)
\end{aligned}
$$

Note that

$$
M_{\lambda_{1}+\lambda_{2}+p+1-k, 0, \lambda_{3}-p}\left(x_{1}, x_{2}\right)=M_{\lambda_{1}+\lambda_{2}+p+1-k}\left(x_{1}-x_{2}\right) M_{\lambda_{3}-p}\left(x_{2}\right)
$$

If $\lambda_{3}-p \geq 2$, then $M_{\lambda_{3}-p}$ is continuous everywhere. Moreover, for fixed $\delta, 0<$ $\delta<1$, and $i=\left(i_{1}, i_{2}\right) \in Z^{2}$,

$$
\begin{aligned}
\lim _{\varepsilon \rightarrow+0}[ & M_{\lambda_{1}+\lambda_{2}+p+1-k}\left(i_{1}-i_{2}+\delta e_{1}+\varepsilon e_{2}\right) \\
& \left.-M_{\lambda_{1}+\lambda_{2}+p+1-k}\left(i_{1}-i_{2}+\delta e_{1}-\varepsilon e_{2}\right)\right]=0 .
\end{aligned}
$$

This shows that

$$
J_{2}\left[D_{3}^{p}\left(-D_{1}\right)^{k-1-\lambda_{2}-p}\left(\sum\left(\nabla_{2}^{\lambda_{2}} a\right)(j) M_{\lambda_{1}, 0, \lambda_{3}}(\cdot-j)\right)\right]=0
$$

unless $p=\lambda_{3}-1$ and $k<|\lambda|$. Thus

$$
\begin{aligned}
& J_{2} D_{2}^{k-1} s \\
& \quad=J_{2}\left[\sum\binom{k-\lambda_{2}-1}{\lambda_{3}-1}\left(-\nabla_{1}\right)^{k-\left(\lambda_{2}+\lambda_{3}\right)} \nabla_{2}^{\lambda_{2}} \nabla_{3}^{\lambda_{3}-1} a(j) M_{|\lambda|-k, 0,1}(\cdot-j)\right] .
\end{aligned}
$$

By straightforward calculation we have

$$
J_{2} M_{|\lambda|-k, 0,1}\left(i+\delta e_{1}\right)= \begin{cases}M_{|\lambda|-k}\left(i_{1}+\delta\right) & \text { if } i_{2}=0 \\ -M_{|\lambda|-k}\left(i_{1}-1+\delta\right) & \text { if } i_{2}=1, \\ 0 & \text { otherwise }\end{cases}
$$

For simplicity, write

$$
b=\binom{k-\lambda_{2}-1}{\lambda_{3}-1}\left(-\nabla_{1}\right)^{k-\lambda_{2}-\lambda_{3}} \nabla_{2}^{\lambda_{2}} \nabla_{3}^{\lambda_{3}-1} a .
$$

Then the above calculation yields

$$
\begin{aligned}
J_{2} D_{2}^{k-1} s(i) & =\sum_{j_{1} \in Z}\left[b\left(j_{1}, i_{2}\right) M_{|\lambda|-k}\left(i_{1}-j_{1}\right)-b\left(j_{1}, i_{2}-1\right) M_{|\lambda|-k}\left(i_{1}-j_{1}-1\right)\right] \\
& =\sum_{j_{1} \in Z} \nabla_{3} b\left(j_{1}, i_{2}\right) M_{|\lambda|-k}\left(i_{1}-j_{1}\right) \\
& =R_{1,|\lambda|-k} \nabla_{3} b(i)
\end{aligned}
$$

This proves ( $1^{\circ}$ ) in Case 3. The proof of Lemma 2 is complete.
For simplicity, we denote by $U_{k, r, \lambda}$ the operator appearing on the right-hand side of Lemma 2 $\left(r^{\circ}\right), r=1,2,3$, respectively. Further, let

$$
\begin{aligned}
L_{k, 1, \lambda} & :=\binom{k-\lambda_{2}-1}{\lambda_{3}-1}\left(-\nabla_{1}\right)^{k-\lambda_{2}-\lambda_{3}} \nabla_{2}^{\lambda_{2}}\left(\nabla_{1}+\nabla_{2}\right)^{\lambda_{3}}, \\
L_{k, 2, \lambda} & :=\binom{k-\lambda_{3}-1}{\lambda_{1}-1} \nabla_{1}^{\lambda_{1}} \nabla_{2}^{k-\lambda_{3}-\lambda_{1}}\left(\nabla_{1}+\nabla_{2}\right)^{\lambda_{3}}, \\
L_{k, 3, \lambda} & :=\binom{k-\lambda_{1}-1}{\lambda_{2}-1} \nabla_{1}^{\lambda_{1}}\left(-\nabla_{2}\right)^{\lambda_{2}}\left(\nabla_{1}+\nabla_{2}\right)^{k-\lambda_{1}-\lambda_{2}} .
\end{aligned}
$$

5. An upper bound for the approximation order. Let $E$ be a finite subset of $\mathbf{Z}_{+}^{3}$. Let $S$ be the span of $\left\{M_{\lambda}(\cdot-j) ; \lambda \in E, j \in \mathbf{Z}^{2}\right\}$. In this section, we will give an upper bound for the approximation order of $S$.

We want to put the operators $U_{k, r, \lambda}$ and $L_{k, r, \lambda}$ into a two-dimensional array. Note that $U_{k, r, \lambda}=0$ if $k \leq d=\min _{\lambda}\left\{\lambda_{1}+\lambda_{2}, \lambda_{2}+\lambda_{3}, \lambda_{3}+\lambda_{1}\right\}-1$ or $k \geq|\lambda|$. Thus the only interesting case is $d<k<|\lambda|$. Assume $|E|=n$. There is a one-to-one mapping from $\{1, \ldots, n\}$ onto $E$. The image of $q$ under this mapping is denoted by $\lambda(q)$. Let

$$
\begin{aligned}
& U_{3(k-d-1)+r, q}:=U_{k, r, \lambda(q)}, \\
& L_{3(k-d-1)+r, q}:=L_{k, r, \lambda(q)}, \quad r=1,2,3 . \\
& R_{3(k-d-1)+r, q}:=R_{r, \lambda(q)-k},
\end{aligned}
$$

We observe that $L_{k, r, \lambda}$ are homogeneous polynomials in $\nabla_{1}$ and $\nabla_{2}$ of degree $k$. Let

$$
\beta_{3(k-d-1)+r}=k, \quad r=1,2,3
$$

We are now in a position to prove the main result of this paper.
THEOREM 1. If $3(m-d) \geq n$, and if the determinant of $L=\left(L_{p q}\right)_{p, q=1}^{n}$ is nonzero, then the approximation order of $S$ does not exceed $m$.

Proof. Suppose to the contrary that to any $h>0$ and any $f \in C^{(m+1)}$ with $\|f\|_{m+1, \infty}<\infty$ there corresponds $u_{h} \in S_{h}$ such that $\left\|f-u_{h}\right\| \leq \varepsilon_{h} h^{m}$ with $\varepsilon_{h} \rightarrow 0$ as $h \rightarrow+0$. It follows that

$$
\begin{equation*}
\left\|\sigma_{1 / h} f-\sigma_{1 / h} u_{h}\right\| \leq \varepsilon_{h} h^{m} \tag{5}
\end{equation*}
$$

(Recall that $\sigma_{1 / h}$ is a scaling operator. See $\S 1$.) Assume

$$
u_{h}=\sum_{\lambda} \sum_{j} a_{\lambda, h}(j) M_{\lambda}(\dot{\grave{h}}-j) .
$$

Then

$$
\sigma_{1 / h} u_{h}=\sum_{\lambda} \sum_{j} a_{\lambda, h}(j) M_{\lambda}(\cdot-j) .
$$

Suppose that $f$ is a polynomial on a square $Q$. Then $\sigma_{1 / h} f$ is a polynomial on the square $Q / h$. In each component of $R^{2} \backslash \Delta$ included in this square, $\sigma_{1 / h}\left(f-u_{h}\right)$ is a polynomial, so we can invoke Markov's inequailty and obtain

$$
\left\|D_{2}^{k-1} \sigma_{1 / h} f-D_{2}^{k-1} \sigma_{1 / h} u_{h}\right\| \leq \text { const } \varepsilon_{h} h^{m}
$$

Moreover, since $K_{1}$ and $J_{2}$ both are bounded operators, we have

$$
\left\|K_{1} J_{2} D_{2}^{k-1} \sigma_{1 / h} f-K_{1} J_{2} D_{2}^{k-1} \sigma_{1 / h} u_{h}\right\| \leq \text { const } \varepsilon_{h} h^{m} .
$$

But $f \in C^{(m+1)}$; hence

$$
K_{1} J_{2} D_{2}^{k-1} \sigma_{1 / h} f=0 \quad \text { for } k \leq m
$$

Thus

$$
\left\|K_{1} J_{2} D_{2}^{k-1} \sigma_{1 / h} u_{h}\right\| \leq \operatorname{const} \varepsilon_{h} h^{m}
$$

By Lemma 2,

$$
K_{1} J_{2} D_{2}^{k-1} \sigma_{1 / h} u_{h}=\sum_{\lambda} U_{k, 1, \lambda} a_{\lambda, h}
$$

hence

$$
\left\|\sum_{\lambda} U_{k, 1, \lambda} a_{\lambda, h}\right\| \leq \text { const } \varepsilon_{h} h^{m} .
$$

The above estimate is also true for $r=2$ or 3 :

$$
\begin{equation*}
\left\|\sum_{\lambda} U_{k, r, \lambda} a_{\lambda, h}\right\| \leq \text { const } \varepsilon_{h} h^{m} . \tag{6}
\end{equation*}
$$

Let

$$
a_{q}:=a_{\lambda(q), h}, \quad q=1, \ldots, n
$$

and

$$
\begin{equation*}
\xi_{p}:=\sum_{q=1}^{n} U_{p q} a_{q} . \tag{7}
\end{equation*}
$$

Then (6) reads

$$
\begin{equation*}
\left\|\xi_{p}\right\| \leq \text { const } \varepsilon_{h} h^{m}, \quad p=1, \ldots, n \tag{8}
\end{equation*}
$$

Let

$$
\mathbf{a}=\left(a_{1}, \ldots, a_{n}\right)^{\tau}, \quad \boldsymbol{\xi}=\left(\xi_{1}, \ldots, \xi_{n}\right)^{\tau}
$$

Here $\tau$ means "transpose". Equation (7) can be written

$$
\begin{equation*}
U \mathbf{a}=\boldsymbol{\xi} \tag{9}
\end{equation*}
$$

where $U$ is the matrix $\left(U_{p q}\right)_{p, q=1}^{n}$.
Let $I_{n}$ be the $n \times n$ identity matrix. Let $\operatorname{adj}(U)$ be the adjugate matrix of $U$. Then

$$
U(\operatorname{adj} U)=(\operatorname{adj} U) U=(\operatorname{det} U) I_{n}
$$

By (9), we have

$$
\begin{equation*}
(\operatorname{det} U) \mathbf{a}=(\operatorname{adj} U) U \mathbf{a}=(\operatorname{adj} U) \boldsymbol{\xi} \tag{10}
\end{equation*}
$$

Take $h$ to be $1 / N$, where $N$ is a positive integer. Let $\beta:=\sum_{p=1}^{n} \beta_{p}$. Then $\operatorname{det} U$ has the form

$$
\operatorname{det} U=\sum_{\alpha_{1}+\alpha_{2}=\beta} R_{\alpha_{1}, \alpha_{2}} \nabla_{1}^{\alpha_{1}} \nabla_{2}^{\alpha_{2}}
$$

where $R_{\alpha_{1}, \alpha_{2}} \in A$, the algebra generated by the shift operators (see $\S 2$ ), and $\left\|R_{\alpha_{1}, \alpha_{2}}\right\| \leq$ const. Assume adj $U=\left(V_{p q}\right)_{p, q=1}^{n}$. Then each $V_{p q}$ has the form

$$
V_{p q}=\sum_{\alpha_{1}+\alpha_{2}=\beta-\beta_{p}} R_{\alpha_{1}, \alpha_{2}}^{(p, q)} \nabla_{1}^{\alpha_{1}} \nabla_{2}^{\alpha_{2}}
$$

with $R_{\alpha_{1}, \alpha_{2}}^{(p, q)} \in A$ and $\left\|R_{\alpha_{1}, \alpha_{2}}^{(p, q)}\right\| \leq$ const. Let

$$
W:=h^{\beta} H_{1}^{\beta} H_{2}^{\beta}(\operatorname{det} U)
$$

where $H_{1}$ and $H_{2}$ are the operators defined in (4). We observe that

$$
\nabla_{r} H_{r}=\left(I-T_{r}\right)\left(\sum_{t=0}^{N-1} T_{r}^{t}\right)=I-T_{r}^{N}=\nabla_{r, N} \quad(r=1,2,3)
$$

Hence

$$
W=\sum_{\alpha_{1}+\alpha_{2}=\beta} R_{\alpha_{1}, \alpha_{2}} h^{\beta} H_{1}^{\beta-\alpha_{1}} H_{2}^{\beta-\alpha_{2}} \nabla_{1, N}^{\alpha_{1}} \nabla_{1, N}^{\alpha_{2}}
$$

Since $\left\|H_{r}\right\| \leq N$, we have

$$
\left\|h^{\beta} H_{1}^{\beta-\alpha_{1}} H_{2}^{\beta-\alpha_{2}}\right\| \leq(1 / N)^{\beta} N^{2 \beta-\left(\alpha_{1}+\alpha_{2}\right)}=1 .
$$

In addition, $\left\|R_{\alpha_{1}, \alpha_{2}}\right\| \leq$ const and $\left\|\nabla_{1, N}^{\alpha_{1}} \nabla_{2, N}^{\sigma_{2}}\right\| \leq$ const; therefore

$$
\begin{equation*}
\|W\| \leq \text { const } \tag{11}
\end{equation*}
$$

Next, we want to estimate Wa. It follows from (10) that

$$
W \mathbf{a}=h^{\beta} H_{1}^{\beta} H_{2}^{\beta}(\operatorname{det} U) \mathbf{a}=h^{\beta} H_{1}^{\beta} H_{2}^{\beta}(\operatorname{adj} U) \boldsymbol{\xi}
$$

Consider $h^{\beta} H_{1}^{\beta} H_{2}^{\beta} V_{p q}$. We have

$$
h^{\beta} H_{1}^{\beta} H_{2}^{\beta} V_{p q}=\sum_{\alpha_{1}+\alpha_{2}=\beta-\beta_{p}} R_{\alpha_{1}, \alpha_{2}}^{(p, q)} h^{\beta} H_{1}^{\beta-\alpha_{1}} H_{2}^{\beta-\alpha_{2}} \nabla_{1, N}^{\alpha_{1}} \nabla_{2, N}^{\alpha_{2}} .
$$

Note that, for $\alpha_{1}+\alpha_{2}=\beta-\beta_{p}$,

$$
\left\|h^{\beta} H_{1}^{\beta-\alpha_{1}} H_{2}^{\beta-\alpha_{2}}\right\| \leq N^{\beta_{p}} \leq N^{m} .
$$

Also $\left\|R_{\alpha_{1}, \alpha_{2}}^{(p, q)}\right\| \leq$ const and $\left\|\nabla_{1, N}^{\alpha_{1}} \nabla_{2, N}^{\alpha_{2}}\right\| \leq$ const. Therefore

$$
\left\|h^{\beta} H_{1}^{\beta} H_{2}^{\beta} V_{p q}\right\| \leq \text { const } N^{m}
$$

This combined with (9) enables us to conclude that

$$
\begin{equation*}
\|W \mathbf{a}\| \leq \text { const } N^{m}\|\boldsymbol{\xi}\| \leq \text { const } \varepsilon_{h} \tag{12}
\end{equation*}
$$

We restrict the domain of $\sigma_{1 / h} f$ and $\sigma_{1 / h} u_{h}$ to $\mathbf{Z}^{2}$. Thus they become elements of $l\left(\mathbf{Z}^{2}\right)$. Let $G_{\lambda} \in A$ be defined by the rule

$$
G_{\lambda} a=\sum a(j) M_{\lambda}(\cdot-j)
$$

Since $\sum M_{\lambda}(\cdot-j)=1$, we have

$$
\left\|G_{\lambda}\right\| \leq 1
$$

Recall that $q \rightarrow \lambda(q)$ is a one-to-one map from $\{1, \ldots, n\}$ onto $E$. Let $G_{q}=G_{\lambda(q)}$. Then

$$
\begin{equation*}
\sigma_{1 / h} u_{h}=\sum_{q=1}^{n} G_{q} a_{q} \tag{13}
\end{equation*}
$$

Substitute (13) into (5). Let $W$ act on both sides of this inequality. Since $\|W\| \leq$ const by (11), we obtain

$$
\left\|W \sigma_{1 / h} f-\sum_{q=1}^{n} G_{q} W a_{q}\right\| \leq \text { const } \varepsilon_{h} h^{m} .
$$

Invoking estimate (12), we have

$$
\left\|\sum_{q=1}^{n} G_{q} W a_{q}\right\| \leq \text { const }\|W a\| \leq \text { const } \varepsilon_{h}
$$

From the foregoing two inequalities we conclude that

$$
\begin{equation*}
\left\|W \sigma_{1 / h} f\right\| \leq \text { const } \varepsilon_{h} \tag{14}
\end{equation*}
$$

Suppose now det $L \neq 0$. Then in the expression

$$
\operatorname{det} L=\sum_{\gamma_{1}+\gamma_{2}=\beta} C_{\gamma_{1}, \gamma_{2}} \nabla_{1}^{\gamma_{1}} \nabla_{2}^{\gamma_{2}}
$$

there exists some $\left(\delta_{1}, \delta_{2}\right)$ such that $\delta_{1}+\delta_{2}=\beta$ and $C_{\delta_{1}, \delta_{2}} \neq 0$. We can find a function $f \in C^{m+1}$ such that $f$ has compact support and

$$
f\left(x_{1}, x_{2}\right)=x_{1}^{\delta_{1}} x_{2}^{\delta_{2}} /\left(\delta_{1}!\delta_{2}!\right) \quad \text { for }\left(x_{1}, x_{2}\right) \in[-\alpha, \alpha] \times[-\alpha, \alpha]
$$

where $\alpha$ is a sufficiently large real number.
Recall that

$$
R_{r, n}=\sum_{t=0}^{n} M_{n}(t) T_{r}^{t}
$$

Since $\sum M_{n}(t)=1$, we have

$$
\begin{aligned}
I-R_{r, n} & =\sum_{t=0}^{n} M_{n}(t)\left(I-T_{r}^{t}\right) \\
& =\sum_{t=0}^{n} M_{n}(t) \nabla_{r}\left(I+\cdots+T_{r}^{t-1}\right)
\end{aligned}
$$

We also have observed that $\nabla_{3}-\left(\nabla_{1}+\nabla_{2}\right)=-\nabla_{1} \nabla_{2}$. Now think of det $U$ as a polynomial in $\nabla_{1}$ and $\nabla_{2}$. Decompose $\operatorname{det} U$ into homogeneous components. Then
the above facts tell us that $\operatorname{det} L$ is its component of the lowest degree. Therefore we may write

$$
\operatorname{det} U=\operatorname{det} L+\sum_{\gamma_{1}+\gamma_{2}>\beta} c_{\gamma_{1}, \gamma_{2}} \nabla_{1}^{\gamma_{1}} \nabla_{2}^{\gamma_{2}}
$$

Let

$$
\gamma=\max \left\{\gamma_{1}+\gamma_{2} ; c_{\gamma_{1}, \gamma_{2}} \neq 0\right\} .
$$

Since $\sigma_{1 / h} f$ is a monomial of degree $\beta$ on the square $[-N \alpha, N \alpha] \times[-N \alpha, N \alpha]$, and since $\operatorname{det} U-\operatorname{det} L$ is a polynomial in $\nabla_{1}$ and $\nabla_{2}$ of degree bigger than $\beta$, we have

$$
(\operatorname{det} U) \sigma_{1 / h} f=(\operatorname{det} L) \sigma_{1 / h} f \quad \text { on } \mathbf{Z}^{2} \cap[-N(\alpha-\gamma), N(\alpha-\gamma)]^{2}
$$

Moreover,

$$
\nabla_{1}^{\gamma_{1}} \nabla_{2}^{\gamma_{2}} \sigma_{1 / h} f=0 \quad \text { if }\left(\gamma_{1}, \gamma_{2}\right) \neq\left(\delta_{1}, \delta_{2}\right)
$$

Hence

$$
(\operatorname{det} L) \sigma_{1 / h} f=c_{\delta_{1}, \delta_{2}} \nabla_{1}^{\delta_{1}} \nabla_{2}^{\delta_{2}} \sigma_{1 / h} f
$$

Furthermore,

$$
\begin{aligned}
H_{1}^{\delta_{1}} H_{2}^{\delta_{2}}(\operatorname{det} L) \sigma_{1 / h} f & =c_{\delta_{1}, \delta_{2}}\left(H_{1} \nabla_{1}\right)^{\delta_{1}}\left(H_{2} \nabla_{2}\right)^{\delta_{2}} \sigma_{1 / h} f \\
& =c_{\delta_{1}, \delta_{2}} \nabla_{1, N}^{\delta_{1}} \nabla_{2, N}^{\delta_{2}} \sigma_{1 / h} f=c_{\delta_{1}, \delta_{2}} \nabla_{1}^{\delta_{1}} \nabla_{2}^{\delta_{2}} f=c_{\delta_{1}, \delta_{2}}
\end{aligned}
$$

Finally, we obtain

$$
\begin{aligned}
W \sigma_{1 / h} f & =h^{\beta} H_{1}^{\beta} H_{2}^{\beta}(\operatorname{det} U) \sigma_{1 / h} f \\
& =h^{\beta} H_{1}^{\beta-\delta_{1}} H_{2}^{\beta-\delta_{2}}\left(H_{1}^{\delta_{1}} H_{2}^{\delta_{2}}(\operatorname{det} U) \sigma_{1 / h} f\right) \\
& =c_{\delta_{1}, \delta_{2}} h^{\beta} H_{1}^{\beta-\delta_{1}} H_{2}^{\beta-\delta_{2}} \mathbf{1} \\
& =c_{\delta_{1}, \delta_{2}} \quad \text { on }[-N(\alpha-\gamma-2 \beta), N(\alpha-\gamma-2 \beta)]^{2}
\end{aligned}
$$

Therefore (14) becomes

$$
\left|c_{\delta_{1}, \delta_{2}}\right| \leq \text { const } \varepsilon_{h}
$$

But $c_{\delta_{1}, \delta_{2}}$ does not depend on $h$. Letting $h \rightarrow+0$ in the above inequality, we obtain $c_{\delta_{1}, \delta_{2}}=0$. This contradiction shows that the approximation order of $S$ does not exceed $m$. The proof of Theorem 1 is complete.
6. The approximation order of $\pi_{k, \Delta}^{\rho}$ in the case $3 \leq 2 k-3 \rho \leq 7$. De Boor and Höllig have shown that $\pi_{k, \Delta}^{\rho}$ has the same approximation order that $S_{\text {loc }}$ does. Here

$$
S_{\mathrm{loc}}:=\text { the span of }\left\{M_{\lambda}(\cdot-j) ; M_{\lambda} \in \pi_{k, \Delta}^{\rho} \text { and } j \in Z^{2}\right\}
$$

(see $\left[\mathbf{B H}_{3}\right]$ ). This fact enables us to apply Theorem 1 to obtain the approximation order of $\pi_{k, \Delta}^{\rho}$ in the case $3 \leq 2 k-3 \rho \leq 7$.

Let

$$
E^{\prime}:=\left\{\lambda ; \rho+2 \leq \min \left\{\lambda_{1}+\lambda_{2}, \lambda_{2}+\lambda_{3}, \lambda_{3}+\lambda_{1}\right\}<|\lambda| \leq k+2\right\} .
$$

Then $M_{\lambda} \in \pi_{k, \Delta}^{\rho}$ is equivalent to $\lambda \in E^{\prime}$. By Lemma 1 , we may reduce $E^{\prime}$ to its subset $E$ such that

$$
S_{\mathrm{loc}}=\text { the span of }\left\{M_{\lambda}(\cdot-j) ; \lambda \in E \text { and } j \in Z^{2}\right\} .
$$

Then we form the matrix $L$ as in $\S 5$ and check whether $\operatorname{det} L \neq 0$. In this way we can prove the following theorem.

## Theorem 2.

$$
\begin{array}{ll}
m(k, \rho)=2 k-2 \rho-1 & \text { for } 2 k-3 \rho=3 \text { or } 4 . \\
m(k, \rho)=2 k-2 \rho-2 & \text { for } 2 k-3 \rho=5,6 \text { or } 7 .
\end{array}
$$

Proof. (i) The case $2 k-3 \rho=3$.
In this case $\rho$ must be an odd number. There exists some integer $\mu \geq 1$ such that $\rho=2 \mu-1$. Then $k=3 \mu$ and $2 k-2 \rho-1=2 \mu+1=\rho+2$. By Lemma 1 ,

$$
S_{\mathrm{loc}}=S_{\mu, \mu+1, \mu+1}+S_{\mu+1, \mu, \mu+1}
$$

Then $E=\{(\mu, \mu+1, \mu+1),(\mu+1, \mu, \mu+1)\}$ and $n=|E|=2$. It is known from $\left[\mathbf{B H}_{1}\right]$ that $m(k, \rho) \geq \rho+2=2 \mu+1$. We want to prove $m(k, \rho)=2 \mu+1$.

We have, for $m=2 \mu+1$, that

$$
L=\left[\begin{array}{cc}
0 & \nabla_{2}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu+1} \\
\nabla_{1}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu+1} & 0
\end{array}\right]
$$

Clearly, $\operatorname{det} L \neq 0$. By Theorem 1 we obtain $m(k, \rho) \leq 2 \mu+1$. Thus

$$
m(k, \rho)=2 \mu+1=2 k-2 \rho-1 \quad \text { in the case } 2 k-3 \rho=3
$$

(ii) The case $2 k-3 \rho=4$.

If $\rho=0$, then $m(2,0)=3$ is a well-known fact. Assume $\rho \geq 1$. There exists an integer $\mu \geq 2$ such that $\rho=2 \mu-2$. Then $k=3 \mu-1$ and $2 k-2 \rho-1=2 \mu+1=$ $\rho+3$. It is known from [DM] that $m(k, \rho) \geq 2 k-2 \rho-1$. We want to prove $m(k, \rho) \leq 2 \mu+1$. By Lemma 1,

$$
S_{\mathrm{loc}}=S_{\mu+1, \mu, \mu}+S_{\mu, \mu+1, \mu}+S_{\mu, \mu, \mu+1}+S_{\mu, \mu, \mu}
$$

For $m=2 \mu+1$, we have

$$
L=\left[\begin{array}{cccc}
\nabla_{2}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu} & 0 & 0 & \nabla_{2}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu} \\
0 & \nabla_{1}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu} & 0 & \nabla_{1}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu} \\
0 & 0 & \nabla_{1}^{\mu}\left(-\nabla_{2}\right)^{\mu} & \nabla_{1}^{\mu}\left(-\nabla_{2}\right)^{\mu} \\
\mu\left(-\nabla_{1}\right) \nabla_{2}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu} & \nabla_{2}^{\mu+1}\left(\nabla_{1}+\nabla_{2}\right)^{\mu} & \nabla_{2}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu+1} & \mu\left(-\nabla_{1}\right)_{2}^{\mu}\left(\nabla_{1}+\nabla_{2}\right)^{\mu}
\end{array}\right] .
$$

Then

$$
\operatorname{det} L=(-1)^{\mu+1} \nabla_{1}^{2 \mu} \nabla_{2}^{3 \mu}\left(\nabla_{1}+\nabla_{2}\right)^{3 \mu}\left(\nabla_{1}+2 \nabla_{2}\right) \neq 0 .
$$

This shows that

$$
m(k, \rho)=2 k-2 \rho-1 \quad \text { in the case } 2 k-3 \rho=4
$$

(iii) The case $2 k-3 \rho=5$.

There exists an integer $\mu \geq 1$ such that $\rho=2 \mu-1$. Then $k=3 \mu+1$ and $2 k-2 \rho-2=2 \mu+2$. It is shown by [J] that $m(k, \rho) \geq 2 k-2 \rho-2$. We want to prove $m(k, \rho) \leq 2 k-2 \rho-2$. By Lemma 1 ,

$$
S_{\mathrm{loc}}=\text { the span of }\left\{M_{\lambda}(\cdot-j) ; \lambda \in E, j \in Z^{2}\right\}
$$

where

$$
\begin{aligned}
& E=\{(\mu+2, \mu+1, \mu),(\mu+2, \mu, \mu+1),(\mu+1, \mu+2, \mu) \\
& \quad(\mu+1, \mu, \mu+2),(\mu+1, \mu+1, \mu),(\mu+1, \mu, \mu+1)\} .
\end{aligned}
$$

Let $m=2 \mu+2$. To check whether $\operatorname{det} L$ is nonzero, we may use the following technique to simplify the computation. We observe that each entry of the matrix $L$ is a polynomial of $\nabla_{1}$ and $\nabla_{2}$, so we may assign values to $\nabla_{1}$ and $\nabla_{2}$. Write $L=L\left(\nabla_{1}, \nabla_{2}\right)$. If $\operatorname{det} L(1,1) \neq 0$, then $\operatorname{det} L \neq 0$. Let us now look at $L(1,1)$ :

$$
L(1,1)=\left[\begin{array}{cccccc}
2^{\mu} & 2^{\mu+1} & 0 & 0 & 2^{\mu} & 2^{\mu+1} \\
0 & 0 & 2^{\mu} & 0 & 2^{\mu} & 0 \\
0 & 0 & 0 & (-1)^{\mu} & 0 & (-1)^{\mu} \\
-\mu 2^{\mu} & -(1+\mu) 2^{\mu+1} & 2^{\mu} & 2^{\mu+2} & -\mu 2^{\mu} & -(1+\mu) 2^{\mu+1} \\
2^{\mu} & 0 & (\mu+1) 2^{\mu} & 0 & (\mu+1) 2^{\mu} & 2^{\mu+1} \\
0 & (-1)^{\mu} & 0 & 2 \mu(-1)^{\mu} & (-1)^{\mu+1} & 2 \mu(-1)^{\mu}
\end{array}\right] .
$$

By straightforward computation, we conclude that $\operatorname{det} L(1,1) \neq 0$. This shows that

$$
m(k, \rho)=2 k-2 \rho-2 \quad \text { in the case } 2 k-3 \rho=5
$$

(iv) The case $2 k-3 \rho=6$ or 7 .

The process goes as before. Since the computation is tedious, we omit the details.
The proof of Theorem 2 is complete.
