# Assessing the Impact of School Subsidy Program in Mexico: Using a Social Experiment to Validate a Dynamic Behavioral Model of Child Schooling and Fertility 

Petra Todd and Kenneth I. Wolpin

## Ex post evaluation

- Policy evaluation based on a randomized experiment.
- The results obtained in the experiments are limited. Usually the data that can be obtained from the experiments are over short time horizon, and the set of policy instrument that can be changed as well as the magnitude of the policy changes are small.
- The program specific treatment effect can be obtained with miminal functional form assumptions. Interpretation of the result is more difficult.

## Ex ante evaluation

- Estimate parameters of a structural behavioral model of decision makers, which are assumed to be policy invariant.
- After the estimation of the structural parameters, wide range of policy experiments can be easily conducted. (Rust: structural models: virtual crash dummies).
- Estimation of structural models often require strong functional form assumptions. In complex models, identification often rely on functional form assumptions.

## Validation of Structural Models Using Randomized Experiments

- Estimate structural models using the data from the control group.
- Based on the estimated strcutural parameters, solve the model given the policy change imposed on the treatment group.
- If the simulated data is close to the data obtained from the treatment group, then the model specification has good predictive performance for policy experiments.
- Once the estimated model is validated by the treatment data, then one can use the model and the parameter estimates for other policy experiments.

## The PROGRESA Program

- Treatment group: 320 villages, control group: 186 villages.
- baseline survey: Oct. 1997, March 1998, followup survey: Oct. 1998, May 1999, November 1999.
- Household demographics, income, school attendance, employment, wages of children of all households in villages.
- local data: distance to nearest secondary school, nearest city.
- household in treatment villages get subsidies if the benefit is one fourth of average family income.
- parents receive subsidies for each grade eligible child that attends school $85 \%$ of the time.
- subsidies increase with the grade level, up to grade 9.
- Data: landless nuclear household, spouse less than 50 years old.
- 1,316 households in control villages, 1,885 households in treatment villages.
- Both eligible and ineligible households were used for estimation.
- School attendance almost universal from age 7 to age 11 .
- Attendance rate decline rapidly after 12 , more for girls.
- Once children leave school, they never return.
- Fertility occurs rapidly after marriage.

## The Model

Parents maximize the discounted present value of lifetime utility:

$$
V(\Omega, t)=\operatorname{Max}_{d_{k}(t)} E\left[\sum_{t=1}^{T} \delta^{\tau-t} U(t) \mid \Omega(t)\right]
$$

$T$ : terminal period: woman's age 59.
Bellman equation:

$$
\begin{aligned}
V(\Omega, t)= & \operatorname{Max}_{k \in K(t)}\left[V^{k}(\Omega, t)\right] \\
V^{k}(\Omega, t)= & U^{k}(t, \Omega(t))+\delta E\left(V\left(\Omega(t+1), t+1 \mid d_{k}(t)=1, \Omega(t)\right)\right) \\
& , t<T \\
V^{k}(\Omega, t)= & U^{k}(T, \Omega(T)), t=T
\end{aligned}
$$

Parents' per period utility function:

$$
\begin{aligned}
U(t)= & U\left(C(t), p(t), n(t), s_{b}(t), s_{g}(t), S_{b}(t), S_{g}(t)\right. \\
& \left., I_{b}(t), \lg (t), z_{s} ; \epsilon(t), \mu\right)
\end{aligned}
$$

$C$ : household consumption.
$p$ : pregnancy
$n$ : history of birth.
$s$ : school attendance.
S: cumulative schooling.
$I$ : children at home (homework).
$\mu$ : household unobserved heterogeneity.
$\epsilon$ : i.i.d. shock.
$z_{s}$ : distance to the nearest village with the secondary school.

## Other

- utility loss of child lagging in grades completed,
- utility loss of child attending grade 10.
- Value of having older girl home depends on whether young children at home.

## Family consumption

$$
C(t)=y_{p}(t)+\sum_{n} y_{o}\left(t, \tau_{n}\right) h\left(t, \tau_{n}\right)
$$

$y_{p}(t)$ : parents' income in time $t$.
$y_{o}\left(t, \tau_{n}\right)$ child's income born in year $\tau_{n}$
Parents' Income

$$
\log _{p}(t)=y_{p}\left(a_{p}(t), z_{c}, \epsilon_{y_{p}} ; \mu_{y_{p}}\right)
$$

$a_{p}$ :husband's age
$z_{c}$ : distance to the nearest city.
$\epsilon_{y_{p}}$ :income shock.
$\mu_{y_{p}}$ : parents specific unobserved heterogeneity.

Other Income

$$
\log \left(y_{o}\left(t, \tau_{n}\right)\right)=y_{o}\left(t-\tau_{n}, I\left(b\left(\tau_{n}\right)=1\right), z_{c}, \epsilon_{y_{o}}(t) ; \mu_{y_{o}}\right)
$$

$b\left(\tau_{n}\right)$ : gender
$t-\tau_{n}$ : age
Grade completion probability

$$
\pi_{c}\left(t, \tau_{n}\right)=\pi\left(t-\tau_{n}, S\left(t, \tau_{n}\right) \mid s\left(t, \tau_{n}\right)=1, \mu_{c}\right)
$$

$S\left(t, \tau_{n}\right)$ : years of schooling
$\epsilon$ : seriall uncorrelated, jointly normally distributed.
$\mu$ : discrete $k$ types.

## Parents' choice variable

- pregnancy
- which children to send to school
- which children to work in the market
- which children to stay home

## Control Sample and Treatment Sample Fit

In general, the model fits well in both control sample and treatment sample.

Table 7
Predicted Selected Characteristics by Unobserved Type

|  | Type 1 |  | Type 2 |  | Type 3 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Girls | Boys | Girls | Boys | Girls | Boys |
| \% of children age 6-11 in school | 98.5 | 99.4 | 97.6 | 99.9 | 78.7 | 64.2 |

| Mean Number Children | 4.20 | 4.25 | 4.23 | 4.25 | 4.29 |

c. The bonus is set at 30,000 pesos for girls and boys.

## Long Term Impacts of Education Subsidy

- The existence of subsidy from the start of marriage would increase years of completed education at age 16 by 0.54 years for both boys and girls.
- Fertility without policy: 4.24 children Fertility with policy: 4.28 children Fertility does not change much.

## Counterfactual Experiments

- Compulsory school attendance between ages 6 to 15. Because of failure rates, mean completed schooling is 8.37 (girls), 8.29 (boys) where the baseline without policy is $(6.29,6.42)$ and the original data $(6.83,6.96)$
- Restrict subsidy to attendance in the 6th grade or higher. Zero subsidy for 3 to 5 grades. Fall in completed schooling : 30 \% (girls), 33 \% (boys), even though attendance of 3 to 5 years old children are almost universal.
No subsidy for young childrens' attendance reduce income to parents, thus induce more work and less school attendance for older children.
- Enforcing child labor law: prohibit children under age 16 to work. Little effect on schooling since they would do home production.
- Build a junior secondary school in every village: increases mean schooling years by 0.1 (girls), 0.13 (boys)

[^0]:    a. based on 200 simulation draws per family
    b. cross-section treatment effect (T98-C98) p-value $\leq .10$
    c. longitudinal treatment effect (T98-T97) p-value $\leq .10$
    d. difference-in-difference treatment effect ((T98-T97) - (C98-C97)) p-value $\leq .10$
