## Abstract

To understand the roles of bcl-2 for the survival of leukemic cells, we constructed human leukemic HL60 transformant lines in which full length bcl-2 antisense message was conditionally expressed by a tetracycline-regulatable expression system. Cell growth was completely inhibited after antisense message induction and massive cell death was induced. Electron microscopic examinations show that cells died by autophagy, but not by apoptosis. The morphology and the function of mitochondria remained intact: neither the reduction in mitochondrial membrane potential nor the nuclear translocation of AIF, a mitochondrial protein that translocates to nuclei in cases of apoptosis, was observed. Caspase inhibitors did not rescue bcl-2-antisense-mediated autophagy. Thus, bcl-2 is essential for leukemic cell survival and its down-regulation results in autophagy. *Cell Death and Differentiation* (2000) 7, 1263–1269.

**Keywords:** autophagy; bcl-2; antisense; tet-ON; HL60

**Abbreviations:** AIF, apoptosis-inducing factor; IMDM, Iscove's Modified Dulbecco's Medium; IL-3, interleukin-3; SCF, stem cell factor; PBS, phosphate-buffered saline; WST, 2-(2-methoxy-4-nitrophenyl)-3-(4-nitrophenyl)-5-(2,4-disulphophenyl)-2H-tetrazolium

## Introduction

Apoptosis and autophagy, the two central mechanisms for programmed cell death,<sup>1–4</sup> play important roles for the elimination of malignant cells. Mitochondria<sup>5</sup> and lysosomes<sup>1–4</sup> are the key organelles in the execution of apoptosis and autophagy, respectively.

The molecular mechanism of apoptosis has been well studied. In the regulation of apoptosis, bcl-2 family proteins play important roles. An oncogene bcl-2 inhibits apoptosis against various toxic stresses through stabilization of mitochondrial membrane potential ( $\Delta\Psi_m$ ).<sup>6</sup> Expressed on the outer mitochondrial membranes, it blocks the release of apoptosis inducer proteins such as cytochrome C,<sup>7,8</sup> AIF,<sup>9</sup> caspase-9 and caspase-2<sup>10</sup> from mitochondria to cytoplasm and thus inhibits the subsequent apoptosis-executing signaling events. It is believed that bcl-2 contributes to tumorigenesis by interfering an appropriate execution of apoptosis against death stimuli. Bcl-2 protein is, however, expressed on other membranous compartments of cells<sup>11,12</sup> and the roles of bcl-2 outside mitochondria and its effects on autophagy remain unknown.

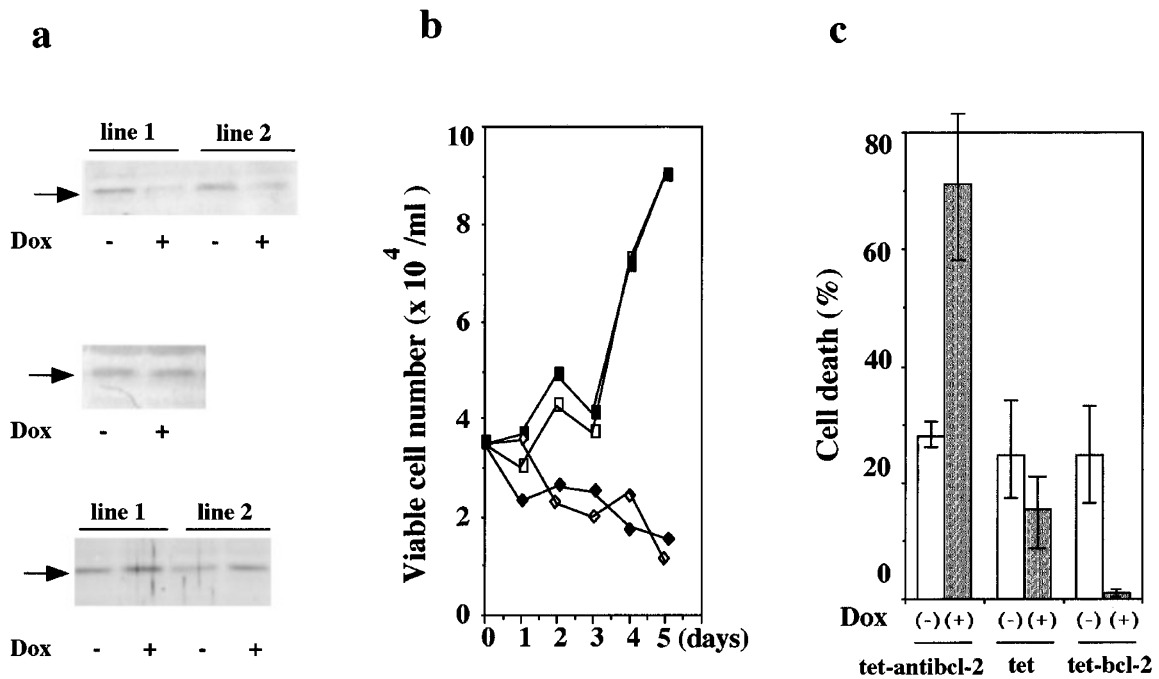

The physiological roles of bcl-2 family proteins have been studied by gene targeting experiments. In contrast to bcl-x<sub>L</sub> knockout mice which are embryonic lethal with massive hemorrhage,<sup>13</sup> bcl-2 knockout mice are viable with almost intact bone marrow functions.<sup>14</sup> Thus, bcl-2 does not seem to be required for normal hematopoiesis. The expression of bcl-2 is, however, often enhanced in leukemic cells especially in malignant cases,<sup>15</sup> suggesting the possible roles of bcl-2 in leukemic cell survival. To address this point and to clarify the roles of bcl-2 in leukemogenesis, we took advantage of a tetracycline-regulatable gene expression system to knockdown Bcl-2 protein in human leukemic HL60 cells.

In this paper we describe the novel extra-mitochondrial role of Bcl-2, showing that down-regulation of Bcl-2 induces an autophagy in leukemic cells. The molecular mechanism of autophagy and possible applications for leukemia therapy will be discussed.

## Results

### Bcl-2 down-regulation induces a massive cell death in leukemic HL60 cells

To study the roles of bcl-2 for the survival of leukemic cells, we took advantage of a tetracycline-regulatable gene expression system. Two transformant lines of human leukemic HL60 cells were prepared, in which the full-length bcl-2 antisense message was inducibly expressed by doxycycline treatment (HL60/tet-antibcl-2). As shown in Figure 1a, Bcl-2 protein expression was apparently reduced after the antisense message induction. On the other hand, no significant changes in Bcl-2 expression were observed in the parental HL60/tet. Two lines of bcl-2-sense-message-expressing transformants were also prepared (HL60/tet-bcl-2), in which Bcl-2 protein expression was up-regulated after doxycycline

**Figure 1** Bcl-2 knockdown by its full-length antisense message induction. (a) The two bcl-2-antisense-message-inducible lines of HL60/tet-antibcl-2 (upper), the parental HL60/tet (middle) and the two bcl-2-sense-message-inducible sublines of HL60/tet-bcl-2 (bottom) were cultured with or without 2  $\mu$ g/ml doxycycline as indicated. After 5 days, cell lysate was prepared from the equivalent number of viable cells and Western blotting was performed. (b) The growth curve of the two lines of HL60/tet-antibcl-2 after doxycycline treatment. (closed square: line-1 doxycycline (-), closed diamond: line-1 doxycycline (+), open square: line-2 doxycycline (-), open diamond: line-2 doxycycline (+)). (c) The percentages of dead cell numbers in HL60/tet-antibcl-2 line 1, HL60/tet and HL60/tet-bcl-2 line 1 at day 5 were shown. Similar results were obtained from line 2 (data not shown). Results from the three independent experiments were shown

**Figure 2** Light microscopic observations of bcl-2-down-regulated cells. HL60/tet-antibcl-2 cells were cultured for 5 days in the absence (upper) or presence (lower) of doxycycline. (a) The direct microscopic observation (magnitude  $\times 100$ ). (b) The Wright-Giemsa staining of the fixed cells (magnitude  $\times 1000$ ). (c) The photographs by Normarsky differentiated interference contrast (DIC) (left) and by Hoechst 33342 staining (right) (magnitude  $\times 400$ )

treatment (Figure 1a, bottom). Using these lines we examined the effect of bcl-2 on the survival of leukemic cells. In HL60/tet-antibcl-2, cell growth was completely inhibited after doxycycline treatment (Figure 1b) and a massive cell death was observed at day 5 (Figures 1c and 2a). In contrast, doxycycline treatment did not affect the growth rate of the parental HL60/tet cells nor HL60/tet-bcl-2 (the percentages of cell number of doxycycline-treated samples against untreated ones at day 5 were  $91.7 \pm 7.64\%$  and  $121.0 \pm 10.6\%$ , respectively). Moreover, no significant changes in dead cell numbers were observed in HL60/tet after doxycycline treatment (Figure 1c). Interestingly, cell death was remarkably suppressed in doxycycline-treated HL60/tet-bcl-2 although basal cell death rates without doxycycline did not significantly differ among HL60/tet-antibcl-2, HL60/tet and HL60/tet-bcl-2 cells (Figure 1c). This finding indicates that the up-regulated expression of Bcl-2 effectively inhibits the death which inevitably occurs during the course of *in vitro* growth as we previously documented as 'the cell-density-dependent apoptosis'.<sup>16</sup> It also supports that doxycycline treatment *per se* may not be toxic or advantageous for HL60 survival, but rather, it only functions in the expressional regulation of the genes of interest in our system.

Thus, bcl-2 plays important roles in the control of leukemic cell survival: its down-regulation induces massive cell death and its up-regulation blocks the induction of an unavoidable cell death observed *in vitro* culture.

### Autophagy, but not apoptosis, is induced by bcl-2 down-regulation

To characterize the cell death induced by bcl-2 down-regulation, morphological examinations were performed. Although the direct observation of cultured cells by inverted microscope showed the shrunk features of bcl-2-down-regulated cells as in a case of apoptosis (Figure 2a), the light microscopic observation after fixation and staining of cells demonstrated the vacuolous changes of cytoplasm with or without chromatin condensation (Figure 2b), suggesting that other types of cell death than apoptosis was executed in these cells. Cells were poorly stained with Hoechst fluorochrome (Figure 2c), which was uncommon to apoptosis. An apoptosis-related intra-nucleosomal DNA breakdown was not detected in 2% agarose electrophoresis (Figure 3a).

Moreover, we could find only a smear-formed chromosomal DNA breakdown, but not the apoptosis-related 50 kbp DNA cleavage, in 0.3% agarose electrophoresis (Figure 3b). These findings strongly suggest that certain mechanisms other than apoptosis were carried out in bcl-2-down-regulated cells.

The concept of cell death can be divided into three categories: the classical caspase-dependent apoptosis, the necrosis with edematous or lytic changes of organelles and the autophagy with multiple autophagic vacuole formation in cytoplasm.<sup>1-4</sup> To understand the cell death mechanism, which had been taken place in bcl-2-down-regulated cells, the electron microscopic examinations were carried out. As shown in Figure 4b, bcl-2-down-regulated cells contained multiple cytoplasmic autophagic vacuoles with intact nuclei. The mitochondria also remained intact with clear crista structure (arrows in Figure 4c). All these findings are compatible to autophagy.

We next examined the mitochondrial function by assessing its membranous potential ( $\Delta\Psi_m$ ). We found no significant changes in the distribution pattern of fluorescence intensity in cells stained by  $\Delta\Psi_m$ -sensitive dye (Figure 5), indicating that the mitochondrial function is well preserved in bcl-2-down-regulated cells. For further confirmation, intracellular localization of AIF, a mitochondrial apoptosis-inducing

**Figure 3** DNA fragmentation assay. Parental HL60/tet or HL60/tet-antibcl-2 cells were cultured in the absence or presence of doxycycline for 5 days as indicated. The low molecular weight chromosomal DNA was extracted and applied on 2% agarose (a) or 0.3% agarose (b)

**Figure 4** Electron microscopic observations of bcl-2-down-regulated cells. HL60/tet-antibcl-2 cells were cultured for 5 days with or without doxycycline and the electron microscopic observation was performed. Doxycycline-untreated (a) and -treated cells (b, c) (magnitude  $\times 1800$  (a, b) and  $\times 3600$  (c)). (An arrow in c indicates the intact mitochondrial crista structure)

protein that translocates to nuclei following the  $\Delta\Psi_m$  reduction in cases of apoptosis,<sup>9</sup> was examined. Actinomycin D treatment induces apoptosis of HL60 cells<sup>17</sup> and a greater number of the cells showed nuclear translocation of AIF (Figure 6a). In contrast, the immunostaining pattern of AIF in doxycycline-treated dead HL60/antibcl-2 cells was completely distinct from that of the nuclei (Figure 6b). This finding indicates that AIF did not translocate to nuclei as in cases of apoptosis, but rather, it remained within mitochondria throughout the course of autophagy.

Thus, bcl-2-down-regulation causes autophagy without the impairment of mitochondrial functions.

### Caspases are not involved in bcl-2-knockdown-mediated autophagy

Because bcl-2 is a well-known anti-apoptosis gene, we investigated the possible involvement of apoptosis-related intracellular signaling events in bcl-2-knockdown-mediated autophagy. First we examined the involvement of caspases, the central actors in apoptosis execution. A broad caspase inhibitor, z-VAD-fmk, was added prior to the bcl-2 antisense

**Figure 5** Mitochondrial membrane potential ( $\Delta\Psi_m$ ) assessment. HL60-tet-antibcl-2 cells were cultured in the absence (left) or presence (right) of doxycycline for 4 days and mitochondrial membrane potential was examined as described in 'Materials and Methods'. Value in each figure indicates the percentage of the cells with reduced  $\Delta\Psi_m$

induction. We found, however, no rescue in the cell viability at day 4 (Figure 7) and day 5 (data not shown), indicating that the bcl-2-down-regulation-induced autophagy was executed in a caspase-independent manner. We next examined the mitochondrial clustering, one of the early events during apoptosis execution,<sup>18</sup> by staining the cells with anti-AIF antibody for the detection of mitochondria. Interestingly, apparent mitochondrial clustering was observed at day 4 before cell death became evident (Figure 8). Thus, bcl-2 down-regulation induces autophagy by a distinct mechanism from caspase activation although certain signaling events common to apoptosis might be involved.

### Bcl-2 protein expression in normal bone marrow CD34<sup>+</sup> cells

It is of importance to know the expression level of Bcl-2 protein in normal hematopoietic progenitor cells when bcl-2 knockdown systems are taken into an account for clinical purposes. Western blotting was performed using the lysate of normal human bone marrow CD34<sup>+</sup> cells. As shown in Figure 9, we could detect no expression of Bcl-2 protein in freshly isolated CD34<sup>+</sup> cells. When cells were cultured with IL-3 and SCF, a weak expression of Bcl-2 protein was detected but in a lesser amount than in the knockdown HL60 cells. Thus, Bcl-2 protein knockdown to the level of normal CD34<sup>+</sup> cells sufficiently induces autophagy in leukemic cells.

### Discussion

We demonstrated that bcl-2 down-regulation results in an induction of autophagy in human leukemic cells without impairing the mitochondrial functions. Our findings not only determine essential roles of bcl-2 in leukemic cells but also confirm the extra-mitochondrial roles of bcl-2. The involvement of bcl-2 in the regulation of autophagy was suggested by a report, which showed the strong enrichment of Bcl-2 protein on the autophagic vacuoles in aged and neurodegenerative-diseased brains.<sup>12</sup> Our results directly proved that bcl-2 functions in the control of autophagy.

**Figure 6** Subcellular localization of mitochondrial AIF protein. (a) HL60 cells were cultured in the absence (upper) or presence (lower) of 1  $\mu$ g/ml of actinomycin D for 5 h. Examination by Normarsky differentiated interference contrast observation, Hoechst 33342 staining and anti-AIF immunostaining was performed as indicated. (b) HL60/tet-antibcl-2 cells were cultured in the absence (upper) or presence (lower) of doxycycline for 5 days and the examination was performed as in a

Although the process of autophagy in mammalian cells is not sufficiently understood, recent studies are now unveiling its molecular mechanism. Two genes, beclin-1<sup>19</sup> and oncogenic ras,<sup>20</sup> have been identified to be responsible for autophagy. Because oncogenic Ras-mediated autophagy could not be blocked by an over-expression of bcl-2,<sup>20</sup> bcl-2 knock down-mediated autophagy may be executed by other mechanisms. It is of note that Beclin-1 is a Bcl-2-interacting protein. It is suggested

that decreased expression of Beclin-1 contributes to the development of human tumors.<sup>19</sup> It may be possible that Bcl-2 interferes with the functions of Beclin-1 during the execution of autophagy in malignant cells and thus contributes to tumorigenesis. In this context, an effective knockdown of Bcl-2 protein expression might be a good therapeutic tool for malignant diseases including leukemia. Whether bcl-2 down-regulation has certain toxic effects on normal hematopoietic stem cells is a matter of importance. The absence of hematopoietic disorder in bcl-2 knockout mice suggests that bcl-2 knockdown is not toxic to hematopoietic stem cells. Although bcl-2 antisense oligonucleotides reportedly inhibit CD34<sup>+</sup> cell survival,<sup>21</sup> this experiment was performed under serum-free conditions. So the *in vivo* effects of bcl-2 knockdown on the survival of hematopoietic stem cells await further investigations. Anyway, the quiescent hematopoietic stem cells are far more resistant to gene transfer than the proliferating leukemia cells. An effective introduction of full-length bcl-2 antisense message by certain vectors may be a benefit for leukemia therapy.

**Figure 7** Involvement of caspase activation in bcl-2-down-regulation-mediated cell death. HL60/tet-antibcl-2 cells were cultured with or without doxycycline for 4 days in the presence of DMSO or 50  $\mu$ M z-VAD-fmk. WST-reducing activity was shown by the percentage to the doxycycline-untreated control (results from three independent experiments were shown)

## Materials and Methods

### Plasmids, cells and reagents

bcl-2 cDNA was from Professor Tsujimoto (Osaka University Medical School Japan). Its coding region was inserted into the *Bam*HI site in tetracycline-responsive-element-containing vector of pTRE2 (Clontech Lab Inc, Palo Alto, CA, USA) either in antisense (pTRE-antibcl-2) or sense (pTRE-bcl-2) direction. Tetracycline-controlled transactivating factor (rTA)-expression vector of pTet-On (Clontech) was transfected into HL60 cells by Gene Pulser II electroporation apparatus (Bio-Rad Lab. Alfred Nobel Drive Hercules, CA, USA) and transformants were selected by 800  $\mu$ g/ml of G418 (WAKO Pure Chemicals Co., Ltd, Osaka, Japan). One

**Figure 8** Occurrence of mitochondrial clustering in bcl-2-down-regulated cells. HL60/tet-antibcl-2 cells were cultured in the absence (upper) or presence (lower) of doxycycline for 4 days and subcellular localization of AIF was examined as in Figure 6

**Figure 9** Bcl-2 protein expression in normal bone marrow CD34<sup>+</sup> cells. Lysates of freshly isolated bone marrow CD34<sup>+</sup> cells (lane 3) and cultured CD34<sup>+</sup> cells in the presence of IL-3 and SCF for 4 days (lane 4) were applied on polyacrylamide gel, and Western blotting was performed using anti-bcl-2 antibody. In lane 1 and lane 2, lysates of HL60/tet-antibcl-2 cells cultured in the absence and presence of doxycycline for 5 days were applied, respectively. The lysate of an equivalent cell number was applied to each lane ( $5 \times 10^4$  cells/lane)

clone showing about twofold increase in tetracycline-responsive-element-containing-luciferase reporter activity after 2 days from the addition of  $2 \mu\text{g/ml}$  of doxycycline (Sigma Chemical Co., St. Louis, MO, USA) was selected as HL60/tet. The pTRE-antibcl-2 or pTRE-bcl-2 was transfected into HL60/tet together with hygromycin-resistant-gene-expression-vector of pTK-Hyg (Clontech) and the transformants were selected by  $100 \mu\text{g/ml}$  of hygromycin. The clones were further selected by checking the decrement or increment of Bcl-2 protein expression after addition of  $2 \mu\text{g/ml}$  of doxycycline. HL60/tet cells were maintained in RPMI1640 (Life Technologies, Inc., Grand Island, NY, USA) supplemented with 10% heat inactivated fetal calf serum and  $800 \mu\text{g/ml}$  of G418. HL60/tet-antibcl-2 and HL60/tet-bcl-2 cells were maintained with further addition of  $100 \mu\text{g/ml}$  of hygromycin. HL60/tet cells were maintained without hygromycin. Normal CD34<sup>+</sup> cells were purchased from Biowittaker Acambrex Co. (Gaithersburg, MD, USA) and cultured with IMDM (Life Technologies) supplemented with 20% fetal calf serum and  $100 \text{ ng}$  of IL-3 (Pepro Tech, Inc., Rocky Hill, NJ, USA) and SCF (Pepro Tech) at the cell density of  $3 \times 10^4/\text{ml}$  in 24 multiwell dish.

### Western blotting and immunostaining

The  $5 \times 10^5$  cells were lysed by  $100 \mu\text{l}$  of  $1 \times$  Laemuli's sample buffer and boiled. The  $10 \mu\text{l}$  of this lysate was applied to SDS-PAGE using 12.5% ( $5 \times 10^4$  cells/lane) and transferred to nitrocellulose membrane. Western blotting of Bcl-2 was performed using anti-bcl-2 monoclonal antibody (Pharmingen, San Diego, CA, USA) as the first antibody, and the second antibody reaction and the final detection procedure were performed as previously described.<sup>22</sup> Immunostaining of AIF was performed as described elsewhere<sup>9</sup> using cells fixed on slide glasses by cytospin apparatus (Cytospin2, Shandon, Pittsburgh, PA, USA) with further fixation with acetone/methanol solution (1 : 3).

### Evaluation of cell death by DNA fragmentation, DNA content analysis and morphological examinations

DNA fragmentation assay was performed by extracting the low molecular weight DNA as previously described.<sup>22</sup> As DNA molecular marker, marker 4 or marker 7 (Wako Pure Chemicals) was used. Morphological study was performed either by culture microscopy (Olympus Optical Co. Ltd, Tokyo, Japan), by light microscopy for cells stained with Wright and Giemsa solution (Muto Pure Chemical Co., Ltd, Tokyo, Japan), by fluorescent microscopy (Olympus) for immunocytochemically-stained cells or by light microscopy with Normarsky differentiated interference contrast (Olympus). For electronmicroscopic study, cells were directly fixed with 1% glutaraldehyde and post-fixed with 2% osmium tetroxide. The cell pellets were embedded in epon resin and cut with an ultramicrotome by  $70 \text{ nm}$  thick. The sections were stained with uranyl acetate and lead citrate and photographed by Bio Medical Laboratories Co. Ltd (Tokyo, Japan).<sup>16</sup>

### Assessment of mitochondrial membrane potential

The  $5 \times 10^5$  cells were collected after 4 days from the induction, washed and resuspended in  $500 \mu\text{l}$  of PBS containing  $5 \mu\text{g/ml}$  of Rhodamin 123 (Molecular Probes, Inc. Eugene, OR, USA). Cells were incubated at  $37^\circ\text{C}$  for 30 min, washed and resuspended in PBS containing  $2 \mu\text{g/ml}$  of propidium iodide (Sigma). Mitochondrial membrane potential was detected by flow-cytometric analysis of Rhodamin 123 accumulation by FACScalibur (Beckton Dickinson, Mountain View, CA, USA). Rhodamin 123 was excited with a 488 nm argon ion laser; fluorescence emission was measured at 530 nm.

### Cell viability assay

Cell viability was measured by WST-reducing activity using Cell Counting Kit-8 (Wako). The cells were incubated for 2 h with WST-8 solution, and then the absorbance at 490 nm (A490) and 595 nm (A595) was determined.

### Acknowledgments

The authors would like to thank Mrs. Satoko Kida Kitaoka for excellent technical assistance. This work was partially supported by a Grant-in-Aid for the Second Term Comprehensive 10-year Strategy for Cancer Control from the Ministry of Health and Welfare, Japan.
