المخلص

يقدم البحث خوارزمية جديدة لتصنيف صور قزحية العين باستخدام البعد الكسري (خوارزمية تغيير البعدين). تقسم التقنية المقترحة الى ثلاث خطوات رئيسية الخطوة الأولى هي عملية التقطيع لتحديد دائرة القزحية ومنطقة البؤبؤ مع إلغاء تأثير الرموش والأجفان ثم يتم تحويل المنطقة المستخلصة الى شكل مربع. في الخطوة الثانية استخلصت السمات للاعتماد على تقنية جديدة هي خوارزمية تغيير البعدين لحساب البعد الكسري للقزحية. وأخيرا استخدمت تقنية Normalized Correlation للتصنيف.

تم تطبيق الخوارزمية المقترحة في هذا البحث على ٩٩٥ صور ذات تدرج رمادي من قاعدة بيانات MMU (Multimedia University)، وتم إيجاد نسبة قبول الخطأ ونسبة رفض الخطأ ونسبة التمييز.

نتائج الخوارزمية أثبتت ان طريقة تغيير البعدين لحساب البعد الكسري هي طريقة جيدة جدا لاستخلاص الصفات حيث أعطت نتائج تمييز عالية. حيث كانت نسبة قبول الخطأ = (1.02) و نسبة رفض الخطأ = (0.52) ونسبة تمييز عالية بنسبة (98.45%).

Abstract

This paper proposes a novel algorithm for the automatic classification of iris images using a 2_D (two Dimension) Variation to estimate the fractal dimensions of the iris.

The new technique divided in to three main step. In the first step the segmentation process in iris recognition is used to localize the circular iris and pupil regions, excluding eyelids and eyelashes. The extracted iris region is normalized into a squares block with constant dimensions.

In the second step, the feature extraction techniques are improved and implemented. A new feature extraction technique based on a 2_D Variation to estimate the fractal dimensions is used. Finally The Normalized Correlation is used to classify the iris features. The techniques performed with perfect segmentation on a set of 995 iris images of greyscale eye images from MMU database. The as False Accept Rate (*FAR*) and False Reject Rate (*FRR*) and (*RR*) recognition rate are calculated for this technique. The results of the algorithm proved that. The a 2D (two Dimension) Variation to estimate the fractal dimensions method it is a good feature extraction technique. It gives *FAR*=(**1.02**) and *FRR*= (**0.52**) and a high recognition rate is **98.45%**..

1. Introduction

Biometrics makes use of certain physiological and behavioral characteristics of a person for identification or verification. These characteristics are called biometric modalities or traits. The physical characteristics like fingerprints, hand geometry, iris, retina, face, hand vein, facial thermo grams, palm print and behavioral characteristics like signature, voiceprint, gait, keystroke dynamics, etc. are examples of biometric modalities [10][12]. Using biometrics for identifying and authenticating human beings offers some unique advantages. Only biometric authentication bases an identification on an intrinsic part of a human being. Tokens, such as smart cards, magnetic stripe cards, physical keys, and so forth, can be lost, stolen, duplicated, or left at home. Passwords can be forgotten, shared, or observed [20][17].

Automated person authentication systems based on iris recognition are reputed to be the most reliable among all biometric methods because of the high level of stability and distinctiveness of the iris patterns [4]. However, the potential requirement of obtaining high accuracy is that users supply iris images of good quality. Current iris recognition systems require only frontal view images of good quality and remove poor quality images by evaluating qualities of images [5] [14] [19].

2. Related Work

Using iris patterns as an approach to personal identification and verification goes back to the late 19th century [8], [21], but most work on iris recognition is done in the last decade. Existing methods for iris recognition mainly concentrate on iris representation and matching which is also one of the focuses of this paper.

Prototype systems had been proposed earlier, John Daugman, implemented a working automated iris recognition system [9][2]. The Daugman system is patented [3]. Daugman's method, based on phase analysis, encodes the iris texture pattern into a 256 byte iris code by using some two dimensional Gabor filters, and taking the Hamming distance [3,4] to match the iris code. Wildes [19] matches images using Laplacian pyramid multi-resolution algorithms and a Fisher classifier. The Daugman system is the most successful and most well know have been developed.

Ma et al. [13] construct a bank of spatial filters whose kernels are suitable for use in iris recognition. They have also developed a preliminary Gaussian-Hermite moments-based method which uses local intensity variations of the iris [11]. They recently proposed an improved method based on characterizing key local variations [9]. Yu et al.[23] use box-counting method to estimate the fractal dimensions of the iris, then classify iris images into four categories in accordance with the fractal dimensions.

3. Iris Recognition System

Generally iris recognition system is composed of many stages as shown in Figure(1). Firstly, an eye image is captured by the system and preprocessed. Secondly, the image is localized to determine the iris boundaries. Thirdly, the iris boundary coordinates are converted to the stretched polar coordinates to normalize the scale and illumination of the iris in the image. Fourthly, features representing the iris patterns are extracted based on texture analysis. Finally, a human is identified by comparing his iris with the iris database [18].

3.1 Iris Database

The iris classification algorithm which is proposed in this paper was trained and tested on MMU2 iris database which consists of 995 iris images. The iris images are collected using Panasonic BM-ET100US Authenticam and its operating range is even farther with a distance of 47-53 cm away from the user. These iris images are contributed by 100 volunteers with different age and nationality. They come from Asia, Middle East, Africa and Europe. Each of them contributes 5 iris images for each eye. There are 5 left eye iris images which are excluded from the database due to cataract disease. Due to some privacy issue.

Biometric Identification Based on Iris Recognition.

3.2 Preprocessing

The iris region has two main circles, iris circle and pupil circle. The pupil always lies in a dark area in the iris region, an iris also displays a variety of textures which can be broadly classified.

Pupil Detection by Using (2×2) Mask with ones coefficients, The result of the masked image is threshold, by this the pupil coordinates are detected.

Canny edge detection is used for generate an edge map. Then the circular Hough transform for the iris/sclera boundary is performed. From the above techniques all important parameters are calculated(radius and center coordinates for both pupil and iris circles)[4][5].

After localizing an iris, the inner and outer boundaries are detected. In an eye image, the iris may be partially concealed by the upper eyelid, the lower eyelid, or the eyelash. To exclude these influences, image preprocessing directional filter.

As the size of an iris in a captured image always varies, the detected iris is normalized. The normalization is used to convert the Cartesian coordinate (x,y) to a polar coordinates (r,θ). Figure (2a) show normalization technique.

The remapping of the iris region from (x,y) Cartesian coordinates to the normalized non-concentric polar representation is modeled as

$$I(x(r, \theta), y(r, \theta)) \rightarrow I(r, \theta) \quad \dots\dots\dots 1$$

with

$$x(r, \theta) = (1-r)x_p(\theta) + rx_i(\theta) \quad \dots\dots\dots 2$$

$$y(r, \theta) = (1-r)y_p(\theta) + ry_i(\theta) \quad \dots\dots\dots 3$$

where $I(x,y)$ is the iris region image, (x,y) are the original Cartesian coordinates, (r, θ) are the corresponding normalized polar coordinates, and are the coordinates of the pupil and iris boundaries along the θ direction[23]. Figure (2b) show Cartesian and polar coordinates of an iris.

3.3 Feature Extraction

An iris image has a unique and complex structure made up of numerous minute interlacing characteristics such as freckles, coronas, furrows, stripes, and crypts. Nonetheless, an iris also displays a variety of textures which can be broadly classified. These textures can be represented numerically, as a calculation of the fractal dimension. The calculation of the fractal dimension begins with preprocessing the original image to localize and normalize the iris[23].

3.3.1 Fractal Dimension

In order to understand the fractal dimension exactly in the field of images processing, it is necessary to describe the topological dimension[16][8]. The topological dimension will be the same for a straight line or a curve, whereas the topological dimension for the bi-dimension (dual dimension) shapes or surface will be two like a square, rectangle and the topological dimension for the tri-shapes like the cube and the cylinder will be three. It will be difficult to decide the topological dimension for the landscape (natural shape) like mountains, clouds, trees, sky...etc. As it is difficult to use the traditional geometry in finding the dimension of this sort of shapes the fractal geometry has been used to calculate the fractal dimension of these shape [7][8].

There are three methods used in calculating the fractal dimension of the digital images. these are: The compass method, the Box Counting method, and the 2_D Variation Method [15][8].

- The 2D Variation Method

The 2D variation method algorithm is an analysis of the pixel environment, and it is one of the best methods used in calculating the fractal dimension of gradating gray image for all scales r as r represents the side length of the square surrounding the pixel whose fractal dimension is to be calculated (r is calculated by the number of the pixel). To calculate the fractal dimension by using this method, the image centre can be specified by the use of certain scale, and r value is specified then the square gradating value is calculated together with its algorithm. By repeating the process with the change of the scale, it will be possible to approximate r value (3, 5, 7,...); the predilection calculation can be carried out from $\log(1/r)$ and $\log N(r)$ such as values as illustrated in the equation and S value will be obtained:

$$S = \frac{\log N}{\log(1/r)} \quad \dots\dots(4)$$

Finally, the fractal dimension is calculated from the following equation

$$D = 3 - \frac{S}{2} \quad \dots\dots(5)$$

Figure (ξ) illustrates the 2D variation method by the use of three different dimensions for r [$r=5, r=7, r=9$] [7][8]:

Figure (ξ): 2D variation method

4. Algorithm for Calculating the Fractal Dimension by the Use of 2D Variation Method

The steps of 2D variation method algorithm are [7][8]:

- 1- Reading the image and changing its two dimensions into similar dimensions.
- 2- Finding the image's center pixel.
- 3- Specifying window w with two dimensions r as r represents the pixel numbers for the window dimension and the window centre is symmetric with the centre of the image.
- 4- Calculating the number of the pixel which contains the $N(r)$ texture and which is in the domain of w .
- 5- Calculating $\log N(r)$, $\log (1/r)$.
- 6- Increasing the w window dimension by two pixels and in all directions. The steps from 4 to 6 are repeated until the w window is covered by the image.
- 7- Calculating the linear regression S from $\log N(r)$ values by depending on the scale values of $\log (1/r)$.

8- Calculating the fractal dimension from the following equation:

$$D = 3 - \frac{S}{2}$$

5. Classifying an iris using the Normalized Correlation:

Normalized correlation between the acquired and database representation was used for goodness of match [21]. This is represented by the following equation:

$$NC = \frac{\sum_{i=1}^n \sum_{j=1}^m (p_1[i, j] - \mu_1)(p_2[i, j] - \mu_2)}{nm\sigma_1\sigma_2} \dots\dots\dots (6)$$

σ_1 are the mean and standard deviation of p_1 , and μ_2 and σ_2 are the mean and standard deviation of p_2 . Normalized correlation is advantageous over standard correlation, since it is able to account for local variations in image intensity that corrupt the standard correlation calculation [21].

6. Experimental Results

Tests are carried out to confirm that iris recognition can perform accurately as a biometric for recognition of individuals. Experiments are also conducted in order to confirm the uniqueness of human iris patterns.

To obtain the maximum features in the irises, the iris region is normalized to 256×64 for radial and angular resolution for the Fractal Dimension implementation, a preprocessed iris image are divided into blocks.. 128×64 image blocks were obtained from original iris image. This blocks are concatenate to convert image to a square shape (128×128 pixels). Then 2D Variation method were used with different windows size (5,7,9,13,17,19,23) to calculate the fractal dimensions of these image blocks.

Errors and recognition rate for the proposed and improved techniques are investigated. Errors are known as False Accept Rate (*FAR*) and False Reject Rate (*FRR*) which are given by [22]:

$$FAR = \frac{\text{Number of incidents of false accepted}}{\text{Total number of samples}} \times 100\% \dots (7)$$

$$FRR = \frac{\text{Number of incidents of false rejected}}{\text{Total number of samples}} \times 100\% \dots (8)$$

while the recognition rate is given by:

$$RR \% = 100 - (FAR + FRR) \dots\dots\dots (9)$$

Table(1) shows the performance of the new algorithm which proposed in this paper with different window size. The proposed algorithm gives a recognition rate of **98.45%** with FAR of **1.022%** and FRR of **0.52%**.

Table (1): shows the performance with different window size

Window size	FAR	FRR	RR
5	8.4335	0	91.5665
7	1.022381	0.522321	98.455298
9	6.191655	1.832571	91.975774
13	0	3.370787	96.629213
17	7.228916	0	92.771084
19	0.787402	1.574803	97.637795
23	4.36659	1.33782	94.29559

7. Conclusion

The human iris contains a very unique pattern that can be used as the basis for biometric identification of individuals. this paper presents a novel iris classification algorithm based on 2D (two Dimension) Variation method of fractal dimension. The iris recognition system has revealed a number of interesting conclusions. It can be stated that segmentation is the critical stage of iris recognition, since areas that are wrongly identified as iris regions will corrupt biometric resulting in very poor recognition.

The classification method has been tested and evaluated of 995 iris images of greyscale eye images from MMU database. the best result was obtained using the window size 7 which was 98.45% accurate. It is a good performance for iris identification.
