## ABSTRACT

This report presents 1998 data on U.S. births according to a wide variety of characteristics. Data are presented for maternal demographic characteristics, including: (1) age, live-birth order, race, Hispanic origin, marital status, and educational attainment; (2) maternal lifestyle and health characteristics, such as medical risk factors, weight gain, and tobacco and alcohol use; (3) medical care utilization by pregnant women, including prenatal care, obstetric procedures, complications of labor and delivery, attendant at birth, and method of delivery; and (4) infant health characteristics, including period of gestation, birthweight, Apgar score, abnormal conditions, congenital abnormalities, and multiple births. Also presented are birth and fertility rates by age, live-birth order, Hispanic origin, and marital status. Selected data by mother's state of residence are shown including teenage birth rates and total fertility rates, as well as data on date of birth, sex ratio, and age of father. Trends in fertility patterns and maternal and infant characteristics are described and interpreted. Birth and fertility rates increased in 1998 by about 1\%, the first increase since 1990. (Contains 60 tables, 9 figures, and 78 references.) (Author/SLD)

#### Abstract

Objectives-This report presents 1998 data on U.S. births according to a wide variety of characteristics. Data are presented for matemal demographic charactenistics induding age, live-bith order, race, Hispanic origin, marital status, and educational attainment; matemal lifestyle and heath characteristics (medical nisk factors, weight gain, and tobacco and alcohol use); medical care utilization by pregnant women (prenatal care, obstetric procedures, complications of labor andor delivery, attendant at bith, and method of delivery); and infant health characteristics (period of gestation, birthweight, Apgar score, abnormal conditions, congenital anomalies, and mudtiple births). Also presented are birth and ferility rates by age, live-bith order, race, Hispanic origin, and manital status. Selected data by mother's State of residence are shown including teenage bith rates and total ferility rates, as well as data on month and day of birth, sex ratio, and age of father. Trends in fertility pattems and matemal and infant characteristics are described and interpreted.

Methods-Descriptive tabulations of data reported on the birth certificates of the 3.94 million births that occurred in 1998 are presented.

Results-Birth and fertility rates increased in 1998 by about 1 percent, the first increase since 1990. Birth rates for teenagers fell 25 percent. Rates for women in their twenties increased 1-2 percent each, whereas rates for women in their thirties rose $2-4$ percent. All measures of childbearing by unmarried women increased in 1998; the number of births rose 3 percent, the birth rate increased about 1 percent while the percent of births that were to unmarried women rose to 32.8 percent. Smoking by pregnant women overall dropped again in 1998, but continued to increase among teenagers. Improvements in prenatal care utilization continued. The cesarean delivery rate increased for the second year after declining for 7 consecutive years. The proportion of multiple births continued to rise; higher order multiple births (e.g., triplets, quadruplets) rose by 13 percent in 1998, following a 14 percent rise from 1996 to 1997 . Key measures of bith outcome-the percents of low bithweight and preterm births-increased. These changes are in large part the result of increases in multiple births.

Keywords: births • birth certificate • matemal and infant health • birth rates • maternal characteristics

## Highlights

Births in the United States increased 2 percent in 1998, to $3,941,553$, the first increase since 1990 . The birth rate rose slightly in 1998 to 14.6 births per 1,000 total population. The fertility rate, which relates births to the number of women of childbearing age, increased 1 percent to 65.6 births per 1,000 women aged 15-44 years.

Fertility rates for women in racial and Hispanic origin subgroups increased 1-5 percent for non-Hispanic white, non-Hispanic black, American Indian, and Puerto Rican women. Rates declined for Asian or Pacific Islander, Mexican, and Cuban women. The variation in rates found for recent years continued in 1998: rates were highest for Mexican women, followed by Puerto Rican, non-Hispanic black, and American Indian women. Rates were much lower for Asian or Pacific Islander, non-Hispanic white, and Cuban women.

The birth rate for teenagers declined again in 1998, falling 2 percent to 51.1 births per 1,000 women aged $15-19$ years. The rate has declined 18 percent since 1991 (62.1). The bith rate for young teenagers 15-17. years fell 5 percent from 1997 to 1998 to 30.4 per 1,000 , a record low. The rate for older teenagers 18-19 years declined

## Acknowledgments

This report was prepared under the general direction of James A. Weed, Acting Chief of the Reproductive Statistics Branch (RSB). Nicholas F: Pace, Chief of the Systems, Programming, and Statistical Resources Branch (SPSRB), and Manju Sharma and Jaleh Mousavi of SPSRB provided computer programming support and statistical tables. Robert N. Anderson of the Mortality Statistics Branch and Lester R. Curtin of the Office of Research and Methodology contributed to the Technical notes. Thomas D. Dunn and Vanetta Harrington of SPSRB and Melissa Park and Janet Gutierrez of RSB provided content review. Staff of the Data Acquisition and Evaluation Branch carried out quality evaluation and acceptance procedures tor the State data files on which this report is based. The Registration Methods staff of the Division of Vital Statistics consulted with State vital statistics offices regarding the collection of birth certificate data. This report was edited by Demarius V. Miller and typeset by Jacqueline M. Davis; graphics were produced by Jarmila Ogburn of the Publications Branch, Division of Data Services.

CDC

2 percent to 82.0. From 1991 to 1998, the rate for young teenagers dropped 21 percent, while the rate for older teenagers declined 13 percent. The declines in birth rates have been steepest for nonHispanic black teenagers; rates fell by 20 to 32 percent. The teenage pregnancy rate declined 15 percent from 1991 (116.5) to 1996 (98.7), reflecting concurrent declines in bith and abortion rates.

The birth rate for women in their early twenties increased in 1998, rising to 111.2 per 1,000 women aged $20-24$ years. The rate for women aged 25-29 years increased 2 percent to 115.9 per 1,000 women. Women in their twenties have the highest birth rates; therefore, their rates are critical to detemining overall childbearing pattems.

Birth rates for women in their thirties increased to 87.4 per 1,000 women aged $30-34$ years, up 2 percent, and to 37.4 per 1,000 women aged $35-39$ years, up 4 percent. The rates for these age groups are at their highest in at least three decades. The birth rate for women aged 40-44 years increased again in 1998 to 7.3 per 1,000.

The first birth rate declined again in 1998, to 26.4 first births per 1,000 women aged $15-44$ years, a record low. The medlan age at first brth increased to 24.3 years; the median has risen slowly but steadily since 1972 (22.0).

The birth rate for unmarried women increased 1 percent in 1998 to 44.3 biths per 1,000 unmarried women aged 15-44 years. The number of biths to unmaried women rose 3 percent to $1,293,567$, the highest number ever reported. Most of the increase was linked to the rise in the number of unmarried women in the childbearing ages. The percent of all births that were to unmarried women increased to 32.8 percent in 1998, compared with 32.4 percent in 1997.

Cigarette smoking durlng pregnancy declined again in 1998, to 12.9 percent. The overall rate has fallen steadily since 1989 . However tobacco use by pregnant teenagers continued to increase in 1998. Sizeable increases were reported for non-Hispanic black teenagers. Overall smoking rates remain lowest for non-Hispanic black, Hispanic, and Asian or Pacific Islander women. Infant bithweight is seriously compromised by matemal smoking: In 1998, 12.0 percent of biths to smokers compared with 7.2 percent of births to nonsmokers weighed less than 2,500 grams ( 5 lb 8 oz ).

The proportion of women beginning prenatal care in the first trimester of pregnancy rose slightly to 82.8 percent for 1998, the ninth consecutive year of increase. Atter showing little change in the 1980's, the percent of women with timely care has risen 10 percent during the 1990's. Gains in first trimester care for 1997-98 were found for all race and ethnic groups except non-Hispanic white mothers. The overall proportion of late or no care was unchanged at 3.9 percent, but is down from a high of 6.4 percent in 1989 . Over the decade, the largest gains in timely care have occurred among groups with the least favorable levels of care: Hispanic, non-Hispanic black, American Indian, and Hawaiian women.

Data on method of deilvery show that the rate of cesarean delivery increased 2 percent between 1997 and 1998 (from 20.8 to 21.2 percent). This was the second consecutive increase in the cesarean rate after declining each year between 1989 and 1996. Despite the recent increase, the cesarean rate in 1998 was still 7 percent lower than in 1989 ( 22.8 percent). The primary cesarean rate in 1998 ( 14.9 per 100 live biths to women who had no previous cesarean) was 2 percent higher than in 1997 (14.6). This was the first time this rate increased during the 1989-98 period. The rate of vaginal birth following a previous cesarean delivery (VBAC) declined 4 percent
between 1997 and 1998 (from 27.4 to 26.3 per 100 births to women who had a previous cesarean). Between 1996 and 1998 the VBAC rate fell 7 percent after increasing 50 percent between 1989 (18.9) and 1996 (28.3). The rate of induction of labor has risen every year since 1989, rising from 9 percent to 19 percent, or nearly one in five births in 1998.

Muitipie births continued to climb in 1998; the number of twin births jumped 6 percent to 110,670 , the largest single year increase in several decades. The number of triplets and other higher order multiple births climbed 13 percent to 7,625 . Since 1980, the twin birth rate has risen 49 percent (from 18.9 to 28.1 per 1,000 live biths), and the triplet and other higher order multiple bith rate has risen 423 percent (from 37.0 to 193.5 per 100,000 ). In 1998 one in every six infants bom to women 45-49 years of age, and one in every three births to women $50-54$ years of age was bom in a multiple delivery.

The rate of preterm birth (less than 37 competed weeks of gestation) increased again for 1998 to 11.6 percent, from 11.4 percent for 1997. The percent of births bom preterm has risen 9 percent since 1990 ( 10.6 percent), and 23 percent since 1981 (from 9.4 percent). Most of the current year rise was among biths bom moderately preterm, or at between 32 and 36 weeks of gestation. For 1997-98, the preterm birth rate increased among non-Hispanic whites ( 9.9 to 10.2 percent) and Hispanics (from 11.2 to 11.4), and was unchanged among nonHispanic blacks ( 17.6 percent). The upswing in preterm births of recent years has been influenced in part by increases in multiple births, which are more likely to be born at shorter gestational ages than singleton biths; the preterm rate has risen slightly for singleton biths.

The overall rate of iow brthweight (LBW) (less than 2,500 grams) rose from 7.5 to 7.6 percent for 1997-98. The percent LBW has increased 9 percent for the 1990's. All of the current year rise, and much of the rise since 1990, is the result of increases in the multiple bith rate (multiple births are at much greater risk of LBW than singletons); LBW among singleton biths declined slightly for 1997-98, from 6.08 to 6.05 percent. Singleton LBW was down slightly for the current year among each of the three largest racial and ethnic groups: non-Hispanic white, non-Hispanic black, and Hispanic.

## lnetroduction

This report presents detailed data on numbers and characteristics of births in 1998, bith and fertility rates, matemal lifestyle and health characteristics, medical services utilization by pregnant women, and infant health characteristics. These data provide important information on fertility patterns among American women by such characteristics as age, live-bith order, race, Hispanic origin, marital status, and educational attainment. Up-to-date information on these fertility patterms is critical to understanding population growth and change in this country and in individual States. Data on matemal characteristics such as weight gain, tobacco and alcohol use, and medical risk factors are useful in accounting for differences in bith outcomes. Information on use of prenatal care, obstetric procedures, complications of labor and/or delivery, attendant at bith and place of delivery, and method of delivery by matemal demographic characteristics can also help to explain differences in bith outcomes. It is very important that data on bith outcomes, especially levels of plurality, low birthweight, and preterm bith, be continuously monitored because these variables are important predictors of infant mortality and morbidity.

A report of preliminary birth statistics for 1998 presented data on selected topics based on a substantial sample (more than 99 percent) of the 1998 birth file (1). The selected measures included birth rates by age, race, and Hispanic origin of mother, and by live-birth order, and biths by marital status, prenatal care, cesarean delivery, and low birthweight. Findings for these selected measures based on the preliminary data are essentially identical to those presented here based on final data.

In addition to the tabulations included in this report, more detailed analysis is possible by using the natality public-use data tape, which is issued for each year. Birth data have also been available in CD-ROM format since 1990, and a selection of tables of detailed data are available on the NCHS Internet site at http://www.cdc.gov/nchs/ biths.htm (2).

## Meithods

Data shown in this report are based on 100 percent of the birth certificates registered in all States and the District of Columbia. More than 99 percent of births occuring in this country are registered (3). Tables that show data by State also provide separate information for Puerto Rico, Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Marianas (Northem Marianas). However, these areas are not included in totals for the United States. Data for the Northern Marianas were available for the first time in 1998.

In this report, tabulations of births beginning with 1980 data are by race of mother; for years prior to 1980, tabulations are by race of child. Details of the differences in tabulation procedure are described in the Technical notes. Text references to black births and black mothers or white births and white mothers are used interchangeably.

Race and Hispanic origin are reported independently on the birth certificate. In tabulations of birth data by race and Hispanic origin, data for Hispanic persons are not further classified by race because the vast majority of women of Hispanic origin are reported as white. Most tables in this report show data for these categories: white, total; white, nonHispanic; black, total; black, non-Hispanic; and Hispanic. Except when presenting birth rates, data for Hispanic subgroups are presented for the following five groups: Mexican, Puerto Rican, Cuban, Central and South American, and other and unknown Hispanic. When reporting birth rates for Hispanic subgroups, births to Central and South American women are added to biths to other and unknown Hispanic women because detailed population data for Central and South American women are not separately available. Data are shown for five Asian or Pacific Islander (API) subgroups: Chinese, Japanese, Hawaiian, Filipino, and "other" API. In addition, nine States report data on API subgroups included in the "other API" category (Vietnamese, Asian Indian, Korean, Samoan, Guamanian, and remaining API); see Technical notes.
U.S. and State-level birth and fertility rates in this report were computed on the basis of population denominators provided by the U.S. Bureau of the Census. Rates by State shown in this report may differ from rates computed on the basis of other population estimates. Additional information on the measurement of marital status, gestational age, and birthweight; the computation of derived statistics and rates; population denominators; random variation and relative standard error, and the definitions of terms are presented in the Technical notes.

Inf-mation on bitths by age, race, or marital status of mother is if it is not reported on the birth certificate. These items were
not reported for less than 1 percent of U.S. births in 1998. (See Technical notes for additional information.) All other maternal and infant characteristics (except items on which length of gestation is calculated) are not imputed; see Technical notes. Biths for which a particular characteristic is unknown are subtracted from the figures for total births that are used as denominators before percents, percent distributions, and medians are computed. Thus, for example, the proportion of women receiving care in the first trimester of pregnancy is computed on the basis of biths for which the month of pregnancy prenatal care began was reported. Levels of nonreporting vary substantially by specific item and by State. Table I in the Technical notes provides information on the percent of records with missing information for each item by State for 1998. Readers should note that the levels of incomplete reporting for some of the medical items are quite high in some States. Data for Connecticut, Hawaii, and Oklahoma, as well as the Northem Marianas, are of particular concem.

## Denographic characteristics

## Births and birth rates

## Number of births

The number of births in the United States increased 2 percent in 1998, to $3,941,553$, compared with $3,880,894$ in 1997. This is the first increase in the number of births since 1990. Between 1990, the most recent high point in U.S. births, and 1997, the number of biths fell 7 percent (see tables 1-12 for national and State brith data by age, Ilve-birth order, race, and Hispanic origin).

The number of blths for nearly all race and Hispanic origin groups increased in 1998 (tables 1 and 6 ). Increases of up to 2 percent were reported for non-Hispanic white and non-Hispanic black births. Biths increased 3 to 4 percent for American Indian, Mexican, Puerto Rican, and Cuban women. Hawaiian biths increased 6 percent. Declines of 1 percent were reported for births to Chinese and Filipino women (data for 1998 are shown in table 13).

## Crude blith rate

The crude birth rate increased from 14.5 live births per 1,000 total population in 1997 to 14.6 in 1998. The increase in 1998 was the first since 1990 (16.7). Between 1990 and 1997, the rate fell 13 percent.

## Feritily rate

The fertility rate, which relates births to the number of women in the childbearing ages, was 65.6 live births per 1,000 women aged 15-44 years in 1998, 1 percent higher than in 1997 (65.0). Like the number of births and the birth rate, the recent high point for the fertility rate was 1990 (70.9); between 1990 and 1997, the fertility rate dropped 8 percent (table 1 and figure 1).

Fertility rates by race and Hispanic origin increased 1 percent each for non-Hispanic white ( 57.7 per 1,000 women aged 15-44 years) and non-Hispanic black women (73.0), 2 percent for American Indian women (70.7), and 5 percent for Puerto Rican women (75.5). Rates fell 3 to 4 percent for Asian or Pacific Islander (API) (64.0) and Mexican women (112.1). The rate for Cuban women dropped from 57.4 to 50.1

Figure 1. Live births and fertility rates: United States, 1930-98
per 1,000 (tables 1 and 6). Birth and fertility rates for specific API groups cannot be computed because the necessary populations are not available.

The modest increases in fertility rates for non-Hispanic white and black women account in large part for the 1 -percent uptum in the overall fertility rate. It is possible that the 7 -year downward trend in U.S. fertility has ended, at least temporarily. During the years 1990-97, the fertility rate for non-Hispanic white women declined 9 percent, and the rate for non-Hispanic black women fell 19 percent. The trends in feribily rates in the 1990's for Mexican, Puerto Rican, Cuban, and API women have not been consistent. The ferility rate for American Indian women has increased modestly for 2 consecutive years, marking a halt in the general downward trend in this rate during the 1990's.

The ferility rate for Hispanic women in 1998 was the lowest reported since 1989 when data accounting for virtually all Hispanic bitths in the United States first became available. The fertility rate for Mexican women in 1998 is also at its lowest since 1989,8 percent below the peak recorded in 1991 (121.6). Trends in fertility for Hispanic women by subgroup for 1989-95 are presented in more detail in a recent report (4).

## Age of mother

Teenagers-The birth rate for the youngest teenagers was 1.0 births per 1,000 females $10-14$ years in 1998, a record low for this age group (table 4). This rate has declined steadily since 1994 (the rate was 1.4 in each year 1989 through 1994). The number of biths to $10-14$-year-olds fell 7 percent from 1997 to 1998, to 9,462 , the lowest total reported in more than three decades ( 8,593 in 1967). The decline in the number of births to very young teenagers occurred solely as a result of the reduction in the birth rate; the number of female teenagers has increased steadily in the 1990's (5).

The birth rate for teenagers 15-19 years fell 2 percent to 51.1 per 1,000 . This rate was 18 percent lower than the recent peak reported in 1991 (62.1) (table A). The declines in the 1990's in the teenage birth rate almost fully reverse the 24 -percent increase that occurred from $1986(50.2$ per 1,000$)$ to 1991. State-specific birth rates for teenagers discussed in the section "Births and birth rates by State."

Table A. Birth rates for teenagers 15-19 by age, race, and Hispanic origin of mother: United States, 1991, 1997, and 1998, and percent change, 1991-98

${ }^{1}$ Includes races other than white and black and origin not stated.
${ }^{2}$ See reference 4 for information on reporting areas in 1991.

Birth rates for teenage subgroups 15-17 and 18-19 years also fell between 1997 and 1998. The rate for teenagers 15-17 years declined 5 percent to 30.4 per 1,000 , a record low $(3,6)$. This rate fell by 21 percent from 1991 (38.7) to 1998 (table 4 and figure 2). The number of biths to teenagers $15-17$ years fell 4 percent from 1997 to 1998 to 173,231 , the fewest since $1987(172,591)$.

The birth rate for older teenagers 18-19 years declined 2 percent, to 82.0 per 1,000 . This rate fell 13 percent from 94.5 in 1992 (its recent high) to 1998. However, the number of births to older teenagers increased 3 percent between 1997 and 1998 to 311,664 , the first increase since 1990 . This increase is due entirely to the 5 -percent rise in the number of female teenagers 18-19 years from 1997 to 1998. (5).

Teenage birth rates by race and Hispanic origin vary substantially (tables 3, 4, 8, and 9). Rates in 1998 were highest for Mexican, non-Hispanic black, Puerto Rican, and American Indian teenagers and lowest for non-Hispanic white, Cuban, and API teenagers, a pattem that has been observed since 1994. Between 1997 and 1998, teenage birth rates declined for all race and Hispanic origin groups except American Indian, Puerto Rican, and "other" Hispanic teenagers. The rate for Mexican teenagers fell 9 percent; declines for non-Hispanic white, non-Hispanic black, and API teenagers were 2 to 3 percent each. The rate for Puerto Rican teenagers rose 8 percent, while the rate for American Indian teenagers increased very slightly.

From 1991, when rates for teenagers generally were at a peak, to 1998 , birth rates fell 19 and 26 percent for non-Hispanic white and

Figure 2. Birth rates by age of mother: United States, 1960-98
black teenagers, respectively. Despite the 8 -percent increase in the rate for Puerto Rican teenagers, their rate in 1998 was still 26 percent lower than its recent peak in 1992 (110.4). The 1998 rates for American Indian and API teenagers were 15 to 16 percent lower, respectively, than in 1991. The rate for Mexican teenagers has declined by 12 percent just since 1995.

Teenage pregnancy rates (based on the sum of live births, induced abortions, and fetal losses) have also declined in recent years (6-8). The pregnancy rate for teenagers $15-19$ years fell 15 percent from 116.5 per 1,000 in 1991 to 98.7 in 1996, reversing an 11-percent rise from 1986 to 1991 (7). (The most recent year for which pregnancy rates are available is 1996.) From 1990 to 1996, pregnancy rates declined 20 to 22 percent for non-Hispanic white ( 68.1 per 1,000 in 1996) and non-Hispanic black (177.8) teenagers. The rate for Hispanic teenagers declined 6 percent from 1994 to 1996 (157.1) (7). Further declines in the teenage pregnancy rate since 1996 are indicated by the steady decline in the teenage birth rate and declines in abortions among teenagers, according to preliminary data (9).

The factors accounting for the current downtum in teenage pregnancy and bith rates are discussed in recent reports ( 6,7 ). Briefly, the proportion of teenagers who are sexually experienced stabilized in the mid 1990's, reversing the steady increases over the past two decades $(7,10)$. Many public and private initiatives have focused teenagers' attention on the importance of pregnancy prevention through abstinence (11). Moreover, teenagers are more likely to use contraceptives at first ERI rse, especially condoms (12). Some sexually active teenagers
have switched to implant and injectable contraceptives, which are effective new birth control methods (13).

Women aged 20 years and over: Women in their twentles-The birth rate for women aged 20-24 years increased 1 percent in 1998 to 111.2 per 1,000, (tables 3, 4,8, and 9). This rate had declined 5 percent during 1990-96, and was unchanged between 1996 and 1997. The birth rate for women aged 25-29 years rose 2 percent in 1998 to 115.9 per 1,000 ; this rate has increased by 3 percent over a 3 -year period, following steady declines during 1990-95. Birth rates for women in their twenties, the principal childbearing ages, have been relatively stable over the past two decades (figure 2).

Birth rates for women in age groups 20-24 and 25-29 years were consistently highest for Mexican women. For example, the rate for Mexican women aged $20-24$ years, 197.6 per 1,000 , was nearly three times the rate for API women in this age group (68.8) and more than double the rate for Cuban women (85.6).

Women in their thirtles-Birth rates for women in their thirties rose again in 1998. Rates for women in these, age groups have generally increased steadily since the late 1970's, a pattem unlike any other age group (tables 4 and 9 and figure 2) (14). The rate for women aged $30-34$ years increased 2 percent in 1998 to 87.4 per 1,000. This rate increased by 67 percent since its low point in 1975 (52.3), and the 1998 rate is higher than any year since 1965 (94.4). Most of this increase occurred by 1990 . Despite the higher bith rate, the number of bitths to women aged $30-34$ years increased only slightly in 1998 because the number of women in that age group declined 2 percent (5).

The blith rate for women in their mid- io laie thirtles increased 4 percent to 37.4 per 1,000 women aged $35-39$ years. This rate has nearly doubled since 1978 (19.0); the 1998 rate is higher than in any year since 1967 (38.3). Although the pace of increase slowed in the 1990's through 1997, the 1998 rate was still 18 percent higher than the rate in 1990 (31.7). The number of births to women aged 35-39 reached a record high in $1998(424,890), 4$ percent more than in 1997, and one-third more than in $1990(317,583)$. All of this increase resulted from the increase in the bith rate; the number of women aged 35-39 years was essentially unchanged in 1998 (5). Among women in their thirties, birth rates were highest for API, Mexican, and "other" Hispanic women (tables 3 and 8).

Women in their forties-The birth rate for women aged 40-44 years increased from 7.1 per 1,000 to 7.3 in 1998. This rate increased nearly a third from 1990 (5.5) to 1998. From 1981 to 1998, the rate increased by 92 percent; the 1998 rate is higher than in any year since 1970 (8.1). From 1997 to 1998, the number of births in this age group rose 6 percent to 81,027; the number has increased by two-thirds during the 1990's.

The birth rate for women aged $45-49$ years remained unchanged at 0.4 births per 1,000 in 1998 . Reflecting the continued increase in the number of women in this age group (who were bom during 1949-53), the number of biths to women aged 45-49 years rose 9 percent to 3,624 , the highest number recorded in three decades (3,790 in 1968).

Births to women aged 50 years and over-Birth data for women aged 50-54 years are reported for the second consecutive year in this report. These data were not available during 1964-96; for that period, mother's age was edited for ages 10-49 years (3). Additional information on the editing procedures is presented in the Technical notes. Because of the recent advances in fertility-enhancing therapies, an increasing number of women are giving birth at age 50 years and over. In 1998, 158 births were reported to women aged $50-54$ years (tables 2 and 7); 54 of these births were part of a multiple delivery (see section below on "Multiple biths"). This number is too small for computing a reliable age-specific birth rate. Therefore, in computing birth rates by age of mother, biths to women aged $50-54$ years have been included with births to women aged 45-49 years; the denominator for the rate is women aged 45-49 years.

Birth rates for women in their mid to late thirties and over increased somewhat more during 1997-98 than earlier in the 1990's when the pace of increase slowed (table 4). Contributing to the renewed rise may be several factors, including increasing bith expectations among childless women as the availability and use of fertility-enhancing therapies has increased (15). Among currently childless women aged $35-44$ years reporting impaired fecundity according to the National Survey of Family Growth, the proportion seeking fertility drug treatment rose considerably from 1982 to $1995(12,16)$.

## Llve-birth order

The first birth rate dropped slightly in 1998 to 26.4 first births per 1,000 women aged 15-44 years (table 5). This is a record low. The 1998 rate was 9 percent lower than in 1990 (29.0), its recent high point. The rates for second, third, and fourth births increased. Birth rates for higher bith orders were unchanged.

While the first birth rate declined less than 1 percent overall, there ; substantial differences in the trends by age of mother (table 3;
tabular data not shown for 1997 and earlier years). Rates declined for teenage subgroups 15-17 and 18-19 years by 5 and 2 percent, respectively. Rates for women in their twenties declined up to 1 percent. In contrast, first birth rates rose 3 to 4 percent for women in their thirties. The proportion of all first births occurring to women aged 30 years and over remained unchanged in 1998 at 23 percent; in 1975 it was just 5 percent (14).

Another measure that can be useful in interpreting age trends in childbearing is the median age at first birth. This measure has gradually increased since the mid-1970's as the tendency for women to postpone childbearing was underway. The median age at first birth was 24.3 years in 1998, compared with 23.8 in 1990 and 22.0 in 1972.

The birth raie for second births to teenagers who have had a first bith increased again slightly in 1998 compared with 1997, after falling 21 percent from 1991 to 1996 (6). All of the decline in teenage birth rates in 1998 was thus due to declines in first bith rates.

## Total fertility rate

The total fertility rate (TFR) indicates the number of births that a hypothetical group of 1,000 women would have if they experienced throughout their childbearing years the age-specific birth rates observed in a given year. This measure shows the potential impact of current fertility patterns on completed family size. Because it is computed from age-specific birth rates, the TFR is age-adjusted; it is not affected by changes over time in age composition.

The TFR in 1998 was $2,058.5,1$ percent higher than in 1997 (tables 4 and 9). The TFR has increased slightly from 1995-by 2 percent overall-following a 3-percent decline from 1990 to 1995. The increase in the TFR in 1998 resulted from the rise in age-specific birth rates for all women in age groups $20-44$ years, which more than compensated for the declines in the teenage birth rates.

The U.S. TFR remains below "replacement" level $(2,100)$, the rate at which a given generation can exactly replace itself. The TFR has been below "replacement" since 1971 ( $2,266.5$ ). TFR's vary substantially among racial and Hispanic origin groups. In 1998, as in recent years, the TFR was above "replacement" for Mexican, non-Hispanic black, and Puerto Rican women. Rates were below "replacement" for American Indian, API , Cuban, and non-Hispanic white women (tables 4, 9, 13, and 14). Increases and decreases between 1997 and 1998 in most TFR's were 2 percent or less; rates declined 3 percent for Mexican and API women and increased 5 percent for Puerto Rican women. Statespecific total ferility rates for 1998 are discussed in the next section.

## Births and birth rates by State

Bith data by race and by Hispanic origin for 1998 are shown in tables 10-12 for the 50 States and the District of Columbia, and Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Northem Marianas. Note that the American Indian, Asian or Pacific Islander (API) and Hispanic populations (and Hispanic subgroups) are highly concentrated geographically.

The number of births increased in 43 States and Guam and American Samoa, and declined in 7 States, the District of Columbia, Puerto Rico, and the Virgin Islands. Increases and declines of up to 3 percent were found in 42 of the States, the District of Columbia, Guam, and American. Samoa. The number increased 4 to 7 percent in

Colorado, Georgia, Idaho, Nevada, North Carolina, Tennessee, and Utah, and declined 5 to 11 percent in North Dakota, Puerto Rico, and the Virgin Islands.

Crude blth rates by State ranged from 11 biths per 1,000 total population (Maine and Vermont) to 22 per 1,000 (Utah) (table 10). Birth rates increased in 32 States and American Samoa, declined in 6 States, the District of Columbia, Puerto Rico, the Virgin Islands, and Guam, and were unchanged in 12 States. Changes were no more than 2 percent in most States, and were not significant in 34 of the States and the District of Columbia or in Guam and American Samoa. A statistically significant decline of 5 percent was recorded for North Dakota.

Fertllity rates per 1,000 women aged 15-44 years ranged by State from a low of 49 (Vermont) to a high of 91 (Utah) (table 10). Rates increased in 42 States, Guam, and American Samoa, and declined in 7 States, the District of Columbia, Puerto Rico, and the Virgin Islands; the rate was unchanged in New York. Changes in most States were no more than 2 percent and were not statistically significant in 23 States, the District of Columbia, Guam, and American Samoa. A significant increase of 5 percent was reported for Colorado, whereas a 4-percent decline was found for North Dakota; the rate for American Samoa fell 24 percent.

State-specific total fertility rates for 1998 are shown in table 10. These rates provide a summary measure of lifetime fertility at the State level; rates for 1980, 1990, and 1996-97 have been published (17-20).

Rates by State for 1998 vary substantially, from a low of $1,569.5$ (or 1.57 births per woman) for Vermont to a high of $2,712.0$ ( 2.71 births per woman) for Utah. Differences in the total fertility rates and changes between 1997 and 1998 by State are quite similar to those in the general fertility rate.

## Blth rates for teenagers

Bith rates for teenagers by age group and State are shown for 1998 in table 10. Rates per 1,000 women aged 15-19 years ranged by State from 24.4 (Vermont) to 73.0 (Mississippi). The highest rate was reported for Guam, 104.8. Birth rates for teenagers have been declining in the United States since 1991. Teenage bith rates were lower in 1998 than in 1997 in all but 9 States. However, the overall trend for the 1990's was downward: Rates for 1998 were lower than for 1991 in all States and the District of Columbia and the Virgin Islands; declines were statistically significant in all States and in the territories except for Puerto Rico and Guam which increased (table B). Declines exceeded 25.0 percent in 5 States, and exceeded 20.0 percent in 13 States, the District of Columbia, and the Virgin Islands. More detailed information on current trends and variations in State-specific teenage birth rates by age, race, and Hispanic origin is presented in recent reports (6,21).

Table B. Birth rates for teenagers aged 15-19 years by State, 1991 and 1998, and percent change, 1991-98: United States, each State and territory
[Birth rates per 1,000 estimated female population aged 15-19 years in each area]

## Sex ratio

There were $2,016,205$ male live biths in 1998 compared with $1,925,348$ female live births. These numbers yielded a sex ratio of 1,047 male per 1,000 female live biths (tabies 13 and 14). The sex ratio has changed very little over the last 50 years and was 1,048 in 1997. Similar to previous years, Asian or Pacific Islander mothers had the highest sex ratio $(1,061)$. The sex ratio for Hispanic mothers $(1,040)$ was intermediate between non-Hispanic white mothers $(1,052)$ and non-Hispanic black mothers ( 1,034 ). The ratio for American Indian biths was 1,038 .

## Month of birth

Monthly bith rates in 9 months of 1998 were above the rates for the same months observed in 1997. The peak months of occurrence of births in 1998 were July, August, and September (table 15). If the birth and fertility rates are adjusted to account for the characteristic seasonal variation, it is then possible to observe the underlying trends in these rates. The months of January, May, and July had the lowest seasonally adjusted birth rates since 1976. The seasonally adjusted birth rate for 7 months was higher in 1998 than for the same months in 1997.

## Day of the week

The average number of births on any given day in 1998 was 10,799 (tabie 16). There is a large variation in the number of births by day of the week. For Tuesdays, the most common day to have a birth, the average was 12,393 while for Sundays, the least common day, the average was 7,829 .

Variation in the daily pattem of births can also be measured by an index of occurrence. In 1998 the Sunday index was 72.5, an indication that there were 27.5 percent fewer births on Sundays than the daily average, considered to be 100.0 . The Saturday index was 80.8 . As in past years, Tuesdays had the highest index in 1998, 114.8.

A weekend deficit is apparent for vaginal and cesarean deliveries, but is far larger for cesarean deliveries, particularly repeat cesareans. In 1998 the Sunday index for vaginal births was 77.6, compared with 63.4 for primary cesareans and 37.9 for repeat cesareans.

## Births to unmarried women

The birth rate for unmarried women in 1998 was 44.3 births per 1,000 unmarried women aged 15-44 years, 1 percent higher than in 1997 (44.0), but still 6 percent below its highest level, 46.9 in 1994. The number of births to unmarried women increased 3 percent to $1,293,567$ in 1998, the highest number ever reported. Most of this 3 -percent increase is due to the 2 -percent growth in the population of unmarried women. The percent of ail births occurring to unmaried women rose from 32.4 to 32.8 percent in 1998. (See tabie C and tables 17,18 .)

The procedures for reporting the mother's marital status changed only in Connectlcut, beginning June 15, 1998. Connecticut now reports the mother's marital status from a direct question, and the question is on the State's birth certificate. The reporting change in Connecticut, which accounts for just 1 percent of U.S. births, is discussed in more detail in the Technical notes. Prior to June 1998, the er's marital status was inferred in Connecticut by comparing the

Table C. Number, rate, and percent of births to unmarried women, and birth rate for married women: United Siates, 1980 and 1985-98

| Year | Births to unmarried women |  |  | Birth rate for married women ${ }^{3}$ |

| 1986. | 878,477 | 34.2 | 23.4 | 90.7 |
| 1985. | 828,174 | 32.8 | 22.0 | 93.3 |
| 1980. | 665,747 | 29.4 | 18.4 | 97.0 |

'Births to unmarried women per 1,000 unmarried women aged 15-44 years.
${ }^{2}$ Percent of all births to unmarried women.
${ }^{3}$ Births to married women per 1,000 married women aged 15-44 years.
sumames of the mother, father, and child. Reporting procedures for marital status in Connecticut are now essentially the same as those in all but two States (Michigan and New York); see Technical notes.

If the reporting change in Connecticut had not occurred, it is estimated that the number of nonmarital births would have been about 1,000 higher. The birth rate and the percent of biths to unmarried women for the Nation, however, were not affected by the change in Connecticut. It is important to note that as a result of the change implemented by Connecticut, its birth data by marital status are more accurate in 1998 than in prior years.

Birth rates for unmarried women vary considerably by race and Hispanic origin. In 1998 the rates per 1,000 unmaried women were 27.4 per 1,000 for non-Hispanic white women, 73.3 for black women, and 90.1 for Hispanic women. The only rate to increase was for non-Hispanic white women, up 1 percent. The birth rate for unmarried black women has declined 19 percent since 1989 (90.7); the 1998 rate is lower than in any year since 1969 when data for black women became available. The birth rate for unmarried Hispanic women in 1998, 90.1 per 1,000, was at its lowest level since 1990 (89.6)

Birth rates for unmarried women by age continue to be highest for women aged 18-19 and 20-24 years, followed closely by women aged 25-29 years (figure 3). Rates for younger teenagers and women in age groups 30 years and over are considerably lower (tables 17 and 18). Among teenagers and women aged $20-24$ years, rates for unmarried black and Hispanic women on average were 2 to 4 times the rates for non-Hispanic white women in the same age groups. Among age groups 25-29 years and over, rates were considerably higher for Hispanic women than for black or non-Hispanic white women.

Age-specific birth rates for unmarried women declined only for teenagers in 1998, continuing a trend underway since 1994. During the 1994-98 period, the rates for unmarried teenagers 15-17 and 18-19 years declined 16 and 8 percent, respectively. The rate for young black teenagers has been falling since 1991, and dropped steeply, by 30 percent, during 1991-98.

Birth rates for unmarried women in age groups 20-24 and 25-29 years increased by 2 and 4 percent, respectively, between 1997 and

Figure 3. Birth rates for unmarried women, by age of mother: United States, 1980-98

1998, reaching record highs in 1998. Bith rates for unmarried women in age groups $30-34$ through $40-44$ years were essentially unchanged in 1998. These pattems by age were generally found for all population groups; among women 30 years and over, increases were found only for non-Hispanic white women.

The proportion of all births occurring to unmarried women increased to 32.8 percent in 1998, compared with 32.4 percent in 1997. The proportions for subgroups in 1998 were 21.9 percent, non-Hispanic white; 69.3 percent, non-Hispanic black; and 41.6 percent, Hispanic; each changed very little in recent years (see tables 13, 14, 17, and 19 for 1998 data).

Changes in the proportion of biths to unmarried women are affected by trends in biths and birth rates for married as well as unmarried women (table C). Because of compensating changes in these measures and in the populations of women by marital status, the proportion of births to unmarried women has changed relatively little since 1994. The birth rate for unmarried women has generally declined, but increased 1 percent from 1997 to 1998. The number of nonmarital births fluctuated during 1994-98, with a small overall increase, reflecting the 6 -percent rise in the number of unmarried women during that period (22). In 1998 total biths-mostly biths to married women-increased for the first time since 1990. However, the increases in the number of unmarried women and their birth rate were larger than the increases in marital fertility. Thus, the proportion of biths to unmarried women rose in 1998. Trends in the factors affecting the number and proportion of biths to unmarried women should be kept in mind when examining trends in these measures (23).

The numbers and proportions of biths to unmarried women by State and by race and Hispanic origin for 1998 are shown in table 19 for the 50 States and the District of Columbia, and each teritory. The numbers increased in 46 States, Guam, and American Samoa, and declined in four States (Califomia, Connecticut, New York, and North Dakota). the District of Columbia, Puerto Rico, and the Virgin Islands. ERIC increases in the proportions exceeded declines: The
proportion increased in 44 States, Puerto Rico, the Virgin Islands, and Guam, declined in three States, the District of Columbia, and American Samoa, and was unchanged in three States.

## Age of father

The birth rate per 1,000 men aged $15-54$ years reversed a 7 year decline in 1998, rising 1 percent to 51.0 (table 20). This rate fell by 14 percent between 1990 and 1997. Birth rates increased for men in age groups 20-24 through $45-49$ years, and declined for teenagers. Information on age of father is often missing on birth certificates of children bom to unmarried women, greatly inflating the number of "not stated" in all tabulations by age of father. In 1990 age of father was not reported for 16 percent of births; by 1998 this figure had declined to 14 percent of births. The procedures for computing birth rates by age of father are described in the Technical notes.

## Educational attainment

The educational attainment of women who give birth is important because higher educational attainment is associated with more timely receipt of prenatal care and fewer lifestyle and health behaviors during pregnancy that are detrimental to bith outcome (discussed in later sections).

Data from the birth certificate show that the educational attainment of women who gave birth increased substantially over the last few decades, partly reflecting the increases in educational attainment of all women during the time period (24). More than three-fourths of women who gave birth in 1998 had at least 12 years of schooling ( 78 percent), and 23 percent had at least 4 years of college (table 21). The percent of mothers with at least a high school diploma increased with additional age, to about 90 percent for women who gave birth in their 30 's, and then declined slightly for mothers 40 years of age and over ( 88 percent). The percent of mothers with at least 4 years of college was highest for women 35 years of age and over ( 43 percent). The median educational attainment for all mothers in 1998 was 12.9 years.

In general, Japanese and Filipino mothers were the most likely to have completed high school-98 percent and 93 percent, respectively (tables 13 and 14). Eighty-seven percent of non-Hispanic white mothers compared with 73 percent of non-Hispanic black mothers and 51 percent of Hispanic mothers had completed high school. Although the overall proportion of Hispanic mothers with at least 12 years of schooling was low, there was tremendous variation among Hispanic subgroups, ranging from 45 percent of Mexican mothers to 87 percent of Cuban mothers (table 14). Only two-thirds of American Indian mothers had 12 or more years of schooling. Thirty percent of nonHispanic white mothers had at least 4 years of college compared with 11 percent of non-Hispanic black mothers and 7 percent of Hispanic mothers.

## Mraternal lifestyle and healft characteristics

## Weight gain

Matemal weight gain is one of the components in the complex relationship between lifestyle characteristics of the mother and the development of the fetus (25). In 1990 the National Academy of Sciences published weight-gain guidelines that varied according to
mother's body mass index (BMI), which is calculated from her prepregnancy weight and height. The guidelines recommend that women who are underweight (low BMI) gain 28 to 40 pounds, those who are of nomal weight (average BMI) gain 25 to 35 pounds, those who are overweight (high BMI), gain 15 to 25 pounds, and obese women, gain not more than 15 pounds (26).

Information on matemal weight gain is collected on the birth certificate, but information on the mother's prepregnancy weight and height is not. Therefore, it is not possible to determine whether the weight gain was within the recommendations for the mother's BMI. Differences between subgroups in matemal weight gain may reflect differences in the proportion of mothers who gained outside the recommended range but could also be the result of group differences in matemal height and prepregnancy weight.

In 1998 all States except Califomia reported information on weight gain. Births to mothers residing in those States accounted for 87 percent of all births in the United States. In 1998 the majority of women ( 64 percent) gained 26 pounds or more during pregnancy (table 22). The median weight gain changed very little during the 1989-98 period and was 30.5 pounds in 1998. Despite the consistency of the median weight gain, the percent of mothers who gained at either end of the weight gain spectrum was higher in 1998 than in 1989 -weight gains of less than 16 pounds increased from 9.4 percent in 1989 to 11.3 percent in 1998, while weight gains of 46 pounds or more increased from 9.1 percent in 1989 to 11.9 percent in 1998.

The weight gain of the mother during pregnancy varled considerably by period of gestation. Mothers who had pretem infants (gestations of under 37 completed weeks) gained 3 pounds less during pregnancy ( 27.9 pounds) than mothers who had babies with gestations of 40 weeks and over ( 30.9 pounds). The median weight gain for non-Hispanic white women ( 30.8 pounds) was about a pound higher than for either non-Hispanic black women ( 29.8 pounds) or Hispanic women ( 30.0 pounds).

The percent of non-Hispanic black mothers who had weight gains of less than 16 pounds ( 16.8 percent) was much higher than for Asian or Pacific Islander (API) and non-Hispanic white mothers ( 9.6 percent each) while American Indian mothers were intemediate ( 15.3 percent) (tables 24 and 25).

Within Hispanic subgroups, the percent of Mexican mothers who gained less than 16 pounds ( 14.7 percent) was nearly double that for Cuban mothers ( 7.8 percent) while the remaining groups were intermediate (table 25).

Matemal welght gain has been shown to have a positive correlation with the birthweight of the Infant (27). This relationship is substantiated by the data in table 23. The percent of infants with low bithweight drops steadily with increasing weight gain through 45 pounds, from 14.2 to 5.1 percent, and then increases slightly for mothers who gained 46 pounds or more ( 5.4 percent). The general decline in the percent low birthweight with greater maternal weight gain is replicated when the data are examined according to the period of gestation.

## Medical risk factors

Matemal medical risk factors have a major influence on pregnancy complications and infant survival (28-30). Some of the more serious conditions necessitate close medical supervision to prevent complications. Sixteen medical risk factors affecting pregnancy
are separately identified on the bith certificate. Data for this item were missing from only 1.4 percent of records for 1998, but birth cerificate data may underreport overall medical risk factor prevalence (31). Also, rates for rarely occurring medical risk factors and for smaller population groups can vary widely from year to year and should be used with caution.

The most frequently reported medical risk factor is pregnancyassoclated hypertension. The rate for this factor rose for the seventh consecutive year, from 36.8 to 37.6 per 1,000 for 1997-98. This rate has risen by nearly a third during the 1990's. (See table 26 for 1998 data.) The pregnancy-associated hypertension rate has risen among all age and race and ethnic groups since the early 1990's. Rates for the related hypertensive disorders, chronic hypertension and eclampsia, were largely unchanged for 1998 , at 7.1 and 3.2 per 1,000 , respectively, and have not risen notably during the 1990's.

Dlabetes and anemla are the second and third most frequently reported complications of pregnancy. The diabetes rate was 26.7 per 1,000 for 1998 compared with 26.4 in 1997. The anemia rate rose to 21.8 from 20.2 in 1997. Despite slight fluctuations in rates for these two conditions, rates have not risen markedly during the 1990's.

Overall, and for the majority of all racial and ethnic groups, the reported rate of hydramnios/ollgohydramnlos (the excess or shortage of amniotic fluid) has consistently increased each year since data for this factor first became available in 1989, and has more than doubled during the 1990's (from 5.9 to 13.2 per 1,000 between 1990 and 1998). Acute or chronic fung dlsease (e.g., asthma, tuberculosis) has exhibited an even more dramatic upward trend. Significant increases for 1990-98 were found for all racial and ethnic groups. Although lung disease is reported in only 1 percent of all pregnant women, the level of lung disease has more than tripled overall since 1990 (from 3.0 per 1,000 to 10.3 between 1990 and 1998).

Medical risk factors during pregnancy vary greatly by race and ethnicly (tables 27 and 28). American Indian women have consistently had the highest rates of pregnancy-associated hypertension, diabetes, and anemia, comprising about 5 percent of all American Indian pregnancies for each condition in 1998. In comparison, only about 1 percent of Chinese mothers had pregnancy-associated hypertension or anemia. Overall rates can sometimes mask striking differences in age-specific rates among racial and ethnic groups. For example, although the overall diabetes rate for white mothers was 25.9 , higher than the black rate of 25.1 , black mothers aged 40 years and over ( 77.7 per 1,000 ) have a rate 28 percent higher than white mothers 40 years and over ( 60.8 per 1,000 ).

Medical risk factor rates also often differ widely by maternal age (table 26). Anemia, for example, is more common among younger mothers ( 30.6 per 1,000 for mothers under 20 years of age compared with 17.6 for mothers 40 years of age and over). Older mothers, conversely, are more prone to chronic conditions such as diabetes ( 65.7 for mothers 40 years and over compared with 8.2 for mothers under 20 years of age). Some risk factors, however, such as pregnancyassociated hypertension follow a U-shaped pattem, with the highest levels at the extremes of the matemal age distribution.

## Tobacco use during pregnancy

Smoking during pregnancy continued to decline according to birth certificate data. In 1998, 12.9 percent of women giving birth were reported to have smoked, down 2 percent compared with 1997
( 13.2 percent) and 34 percent since 1989 ( 19.5 percent), when this information first became available on the birth certificate $(20,32)$. Tobacco use was reported in a comparable manner on the birth certificate in 1998 by 46 States, the District of Columbia, and New York City, comprising 81 percent of U.S. births. Comparable information was not available for Califomia, Indiana, South Dakota, and the remainder of New York State. (See tables 24, 25, and 29-32 for 1998 data.)

Some studies have suggested that smoking may be underreported on birth certificates due to a variety of factors, including the lack of a specific time reference for smoking status, variations in the source of this information for each birth, and the growing stigma associated with smoking (32-35). Nevertheless, trends in matemal smoking based on the birth certificate are generally consistent with those reported for recent years from the National Survey of Family Growth and more recently from the Centers for Disease Control and Prevention's (CDC) Behavioral Risk Factor Surveillance Summary, and variations in smoking among population subgroups found in birth certificate data have been corroborated in other studies ( $12,36-38$ ).

Tobacco use during pregnancy is associated with a variety of adverse outcomes, including increased risk of miscarniage, intrauterine growth retardation, low birthweight, and infant mortality, as well as negative consequences for child health and development (39-42).

Maternal smoking declined or was unchanged in most racial and Hispanic origin groups; smoking rates increased for Japanese and Hawaiian women, the second year of increase for Hawaiians. As in previous years, rates were highest for non-Hispanic white, American Indian, and Hawaiian women, and lowest for Mexican, Cuban, Central and South American, and Asian or Paciicic Islander women (API) (except Hawaiian) (tables 24 and 25). The generally very low smoking rates found for Mexican, Central and South American, Chinese, and Filipino women from bith certilicate data have been confirmed by other studies $(36,37)$. Women bom in the 50 States and the District of Columbia had substantially higher smoking rates than women bom outside these areas, a pattem that has been described elsewhere (tables 24 and 25) (43).

Maternal smoking among teenagers rose about 1 percent overall, the fourth consecutive year of increase, with all of the 1997-98 increase confined to older teenagers (up from 18.8 to 19.2 percent) (figure 4) (32). Smoking rates increased among non-Hispanic white and black teenagers 15-19 years in 1998; the rate for Hispanic teenagers was unchanged at 4.9 percent. The smoking rate for non-Hispanic black teenagers was 7.0 percent in 1998, compared with 5.0 percent in 1994 when the rate began to rise (see table 30 for 1998 data.) The rate for non-Hispanic white teenagers increased to 29.8 percent; their rates are still 4 to 5 times the rates for non-Hispanic black teenagers. NonHispanic white women aged 18-19 years had the highest smoking rate of any group, 30.4 percent (table 30). Smoking during pregnancy generally declined for women in age groups $20-39$ years. Pattems of smoking rates and trends by age, race, and Hispanic origin are described in detail in a recent NCHS report (32).

Among smokers, the proportion smoking at least half a pack of cigarettes dally has declined steadily in recent years-to 31 percent in 1998 (compared with 41 percent in 1990) (32). Non-Hispanic white mothers and older mothers are more likely than other mothers to smoke half a pack or more (tables 29 and 31).

Figure 4. Percent of mothers who smoked during pregnancy by age: Total reporting areas, 1990-98

Smoking rates by maternal educational attainment continue to be highest for women with 9-11 years of education, 26 percent in 1998, and lowest for women with 4 years or more of college, 2 percent (table 31). Even among women aged 20 years and over, smoking rates were highest for mothers who attended but did not graduate from high school-29 percent overall and 48 percent of non-Hispanic white women (tabular data not shown).

Bables borm to mothers who smoke during pregnancy are at greatly elevated risk of low birthweight (LBW), a finding documented in bith certificate data as well as in numerous other studies $(39,44)$. In 1998, 12.0 percent of infants bom to smokers weighed less than 2,500 grams ( 5 lb 8 oz ) compared with 7.2 percent of biths to nonsmokers (table 32). This substantial differential is found for every race and Hispanic origin group. Heavier smoking heightens the LBW risk, although LBW is elevated even among babies bom to the lightest smokers ( 1 to 5 cigarettes daily), 11.0 percent (tabular data not shown). Advancing matemal age exacerbates the risk, probably a consequence of the much greater cigarette consumption among older women (table 29).

## Alcohol use during pregnancy

Pregnancy and bith outcome can be jeopardized by maternal alcohol use during pregnancy. Even low to moderate alcohol use has been shown to jeopardize bith outcome, independent of other risk factors such as tobacco use and other matemal risk factors $(45,46)$. All States except Califomia and South Dakota included items on alcohol use on their birth certificates in 1998. This reporting area accounted for 87 percent of U.S. births.

Alcohol use during pregnancy is substantially underreported on the birth certificate (31). According to bith certificate data, alcohol use declined again in 1998 to just 1.1 percent of mothers reporting any alcohol use compared with 1.2 percent in 1997 and 4.1 percent in 1989, the first year this information was reported on the birth certificates (see tables 24 and 25 for 1998 data) (20). A recent study based on an analysis of responses by about 1,300 pregnant women in CDC's nationally representative Behavioral Risk Factor Surveillance System
found that about 15 percent of women used alcohol during pregnancy in 1995. The researchers also reported that although alcohol use declined from 1988 ( 23 percent) to 1992 ( 10 percent), there was a statistically significant rise to 15 percent in 1995 (47).

The nature of the birth certificate questions on alcohol use apparently has contributed to the underreporting because the questions focus on the number of drinks per week, whereas other studies inquire about drinks per month (47). Women who drink, but less than one drink per week, may report no alcohol use for the birth certificate question. The stigma associated with alcohol use also contributes to the underreporting $(25,47)$.

## Medical services utidization

## Prenatal care

The percent of women who began prenatal care In the first trimester of pregnancy rose for the ninth consecutive year, to 82.8 percent for 1998. This measure of prenatal care showed little improvement during the 1980's, but has risen by 10 percent during the 1990's. (See table D and tables 33-35.) The proportion of mothers with late (care beginning in the third trimester) or no care was 3.9 percent for the current year, unchanged from 1997. The percent of women with late or no care is down from a high of 6.4 percent reported for 1989.

The effects of prenatal care are difficult to quantify ( 48,49 ), but appropriate care can promote healthier pregnancies by detecting and managing preexisting medical conditions, and providing health behavior advice (50). Prenatal care can also serve as a gateway into the health care system, especially for socially disadvantaged women (49).

The proportion of women beginning in the first trimester of pregnancy improved by about 1 percent for the current year for all of the race and ethnic groups except non-Hispanic white women, among whom the level was stable. Since 1989 timely care has risen for all groups, but gains have been most evident among groups with lower levels of timely care. For example, levels continue to be comparatively low, but increases of 19 to 28 percent have been reported among the following groups for the period 1989-98: American Indian, non-Hispanic black, Puerto Rican, Central and South American, and Mexican. (See table E and tables 24 and 25 for 1998 data.). Despite these gains, there remained a 33 -percent differential between the groups with the highest (Cuban at 91.8 percent) compared with the lowest levels (American Indian at 68.8 percent) of timely care.

Improvements in the timely receipt of prenatal care have been quite widespread throughout the country during the 1990's; however, the largest increases have occurred in the South. Five southem States or reporting areas reported increases of about 20 percent or more in the percent of mothers with first trimester care for 1989-98: the District of Columbia, Florida, Georgia, South Carolina, and Texas (table 34 for 1998 data).

The Adequacy of Prenatal Care Utillzation Index (APNCU), an altemative measure of prenatal care utilization, which adjusts for some of the weaknesses of the trimester care began and the Kessner Index, also indicates a slight increase in prenatal care utilization for the current year (51). According to this measure, the proportion of women with at least adequate care rose from 74.0 percent to 74.3 percent between 1997 and 1998 (table F). The proportion of women with intensive use

| 1989. | 24.1 | 42.0 | 15.9 | 18.0 |

NOTES: Levels may differ slightly from those previously published; see Technical notes. See reference 51 for information on calculation of this measure.

College of Obstetricians and Gynecologists' recommendations by a ratio of observed to expected visits of at least 110 percent) was up slightly (from 30.7 to 31.0 percent) and the proportion of women with intermediate or inadequate care declined (from 26.0 to 25.7 percent). For 1989-98, the APNCU shows the percent of mothers with at least
adequate care increasing by 12 percent, (with most of the increase occurring among women with intensive use of care), and the percent of women with inadequate care declining by about one-third.

## Obstetric procedures

The most prevalent obstetric procedure in 1998 was electronic fetal monitoring, reported for nearly 3.3 million births, or 84 percent of all live biths in the United States (table 36). Six specific obstetric procedures are reported on the birth cerificate.

According to data from the birth certificate, 65 percent of mothers who had live biths in 1998 received ultrasound. The overall rates per 1,000 live biths of stimulation of labor and induction of labor in 1998 were 178 (17.8 percent) and 192 ( 19.2 percent) respectively. The rates of both of these procedures have been rising steadily every year since $1989(52,53)$. Some of the increase may be due to better reporting; a study based on 1989 births found that obstetric procedures were underreported on the birth certificate (54). While the highest rates of induction are found for the longest gestation periods as would be expected, rates have been rising for all gestation groups (figure 5).

## Complications of labor and/or delivery

Of the 15 reported complications of labor and/or delivery, 3 were reported at a rate greater than or equal to 30 per 1,000 live births in 1998: Meconium, moderate/heavy ( 55 per 1,000 ), fetal distress ( 40 per 1,000 ), and breech/malpresentation ( 39 per 1,000 ) (table 37 ). Rates for these three complications varied by race and Hispanic origin (tables 27 and 28). It has been shown that levels of these complications may be underreported on the birth certificate (54).

## Attendant at birth and place of delivery

In 1998 more than 9 out of 10 births ( 91.9 percent) were attended by a physician in a hospital, making this arrangement by far the most typical (table 38). However, the percent of biths with this arrangement was slighty lower in 1998 than in 1997 ( 92.3 percent)

NOTES: Louisiana, Nebraska, and Oklahoma did not report induction in 1989. Oklahoma did not report induction in 1990. Rates are plotted on a log scale.
and has declined from 98.4 percent in 1975. For physician-attended births, 4.3 percent were by doctors of osteopathy ( DO 's) while the remaining were attended by doctors of medicine (MD's). Although small, the number and percent of births attended by DO 's has grown steadily since 1989, the first year data on DO's were available from the birth certificate, from 2.8 percent of all births to 4.0 percent. The percent of births attended by midwives increased shaply between 1975 (1.0 percent) and 1998 ( 7.4 percent). A recent report found that nearly all of the growth in midwife-attended births was for those in hospitals (53). About 95 percent of midwife-attended biths in 1998 were by certfiled nurse midwives (CNM's).

About 99 percent of births in 1998 were delivered in hospitals, almost unchanged from the 1975 level. The majority of out-of-hospital births were in a residence ( 63 percent) whereas 29 percent were in a freestanding birthing center.

About 93 percent of biths to non-Hispanic white women were attended by a physician in a hospital compared with about 92 percent of biths to non-Hispanic black women and 90 percent of biths to Hispanic women. Hispanic women were more likely to have midwifeattended hospital biths ( 9 percent) than were either non-Hispanic white or black women ( 6 to 7 percent each).

## Method of delivery

The rate of cesarean dellvery increased 2 percent between 1997 and 1998 (from 20.8 per 100 live biths to 21.2), retuming to the level observed in 1994. This was the second consecutive year that the rate increased after falling each year during 1989-96 (table $\mathbf{G}$ and table 39). Despite the increase, the 1998 rate was 7 percent lower than the rate of 22.8 in 1989, the first year this information was available on the birth certificate. The primary cesarean rate in 1998 ( 14.9 per 100 live births to women who had no previous cesarean) was 2 percent higher than in 1997 (14.6). This was the first time this rate increased during the 1989-98 period; it declined each year between 1989 and 1996 and remained steady between 1996 and 1997 (table G). The primary rate in 1998 was 7 percent lower than in 1989 (16.1) but retumed to the level of 1994. The rate of vaginal bith after previous cesarean dellivery (VBAC) declined 4 percent between 1997 and 1998 -from 27.4 per 100 women with a previous

Table G. Total and primary cesarean rates and vaginal births after previous cesarean delivery rates: United States, 1989-98

| Year | Cesarean rate |  | VBAC rate ${ }^{3}$ |
| :---: | :---: | :---: | :---: |
|  | Total ${ }^{1}$ | Primary ${ }^{2}$ |  |
| 1998 | 21.2 | 14.9 | 26.3 |
| 1997 | 20.8 | 14.6 | 27.4 |
| 1996 | 20.7 | 14.6 | 28.3 |
| 1995 | 20.8 | 14.7 | 27.5 |
| 1994 | 21.2 | 14.9 | 26.3 |
| 1993 | 21.8 | 15.3 | 24.3 |
| 1992 | 22.3 | 15.6 | 22.6 |
| 1991 | 22.6 | 15.9 | 21.3 |
| 1990 | 22.7 | 16.0 | 19.9 |
| 1989 | 22.8 | 16.1 | 18.9 |

[^0]cesarean to 26.3. The VBAC rate has declined 7 percent between 1996 and 1998 after increasing by 50 percent between 1989 and 1996 (from 18.9 to 28.3).

Overall cesarean rates increased steadily with advancing age of the mother and were more than twice as high for mothers $40-54$ years of age (33.1) than for teenagers (14.5) (table 40). Primary cesarean rates increased with additional age after age 24, to 23.3 for women $40-54$ years of age. VBAC rates declined with increasing age-slightly under a third of teenagers who had a previous cesarean had a VBAC delivery ( 31.7 percent) compared with 20.8 percent of mothers 40-54 years of age. All age groups experienced increases in their total cesarean rate between 1997 and 1998 with mothers 25 years of age and over having slightly greater percent increases than younger women. All age groups experienced declines in VBAC rates between 1997 and 1998 except for mothers 40-54 years of age whose rate increased from 20.5 in 1997 to 20.8 in 1998.

Non-Hispanic black women had a higher cesarean rate in 1998 (22.4) than either non-Hispanic white women (21.2) or Hispanic women (20.6). The percent increase between 1997 and 1998 was highest for black women, thus increasing the disparity. Similarly, the primary cesarean rate for non-Hispanic black women (16.0) was higher than the rate for non-Hispanic white women (15.1) and Hispanic women (13.6). All groups experienced increases in their primary cesarean rate from 1997 to 1998, but the percent increase for non-Hispanic black women was slightly higher than for non-Hispanic white and Hispanic women. The VBAC rate in 1998 was highest for non-Hispanic white women (27.3), lowest for Hispanic women (22.4), and intemediate for nonHispanic black women (25.7). The VBAC rate for each group declined between 1997 and 1998 with Hispanic women having a slightly greater percent decline than the other groups.

American Indian and Asian or Pacific Islander (API) mothers had lower cesarean rates (18.6 and 19.4, respectively) than either nonHispanic white or black mothers (tables 24 and 25). With the exception of Filipino mothers, all specified API categories had lower rates of cesarean delivery than either non-Hispanic white or black mothers. The rate of cesarean delivery varied between 19.8 and 22.2 for all Hispanic subgroups except for Cuban mothers whose rate was much higher (31.0) (table 25).

There was considerable variation in cesarean rates by State ranging from a high of 27.0 in Mississippi to a low of 14.7 in Alaska; the rate for Puerto Rico was 35.1 (table 41). There was also considerable variation in VBAC rates by State, from 40.6 in Vermont to 13.1 in Louisiana.

All of the selected medical risk factors in table 42 were associated with overall cesarean rates that were equal to or higher than the national average. Cesarean rates for the medical risk factors ranged from 21.2 for mothers with Rh sensitization to 48.8 for mothers with eclampsia. Certain complications of labor and/or delivery are also associated with high cesarean rates. Nearly all births with cephalopelvic disproportion were cesarean deliveries ( 96.2 ) while the cesarean rates for breech/malpresentation (84.2) and placenta previa (81.5) were also very high.

During the 1989-98 period, the percent of births that were delivered by either forceps or vacuum extraction remained steady at around 9 percent. During that period, however, there was a shift as the number and percent of biths delivered by forceps declined each year whereas $0^{\text {t- }}$ - use of vacuum extraction generally increased (tabular data not
shown). In 1998, 2.6 percent of biths were delivered by forceps compared with 5.5 percent in 1989-a 53 -percent decline. Vacuum extraction was used in 6.0 percent of biths in 1998, a slighty lower proportion than in 1997 (6.2), but 71 percent higher than in 1989 (3.5). The slight decline between 1997 and 1998 in the percent of biths deliveried by vacuum extraction was also apparent when examining vaginal biths only-from 7.8 percent of all vaginal biths in 1997 to 7.7 percent in 1998.

## Infant health characteristics

## Period of gestation

The preterm birth rate rose again for 1998, to 11.6 percent, following a rise from 11.0 to 11.4 percent for 1996-97. The percent of births bom preterm, or at earlier than 37 completed weeks of gestation, has risen 9 percent since 1989-90 (from 10.6 percent), and 23 percent since 1981 ( 9.4 percent). Most of the current year rise was among moderately preterm biths ( $32-36$ weeks), which increased from 9.43 to 9.63 percent; the percent of biths bom very preterm, (prior to 32 completed weeks of gestation) was 1.94 percent for 1997 compared with 1.96 percent for 1998. (See tables 43, 44, and figure 6.) Preterm birth, especially very preterm birth, is a major cause of infant mortality and has been associated with long-term neurodevelopmental and respiratory disorders $(55,56)$.

The steady climb in the preterm rate among non-Hispanic white births continued, rising from 9.9 to 10.2 percent between 1997 and 1998. Since 1989 the non-Hispanic white preterm rate has risen more than 20 percent (from 8.4 percent). This upswing is influenced by increases in the rate of multiple births (multiple births are about 6 times more likely to be bom pretem than singleton births). However, increases in preterm singleton births have also been observed (57) (figure 6). For 1997-98, the percent of non-Hispanic white preterm singletons rose from 8.42 to 8.59 , but most of the rise was among moderately preterm births. Between 1989 and 1998, the singleton preterm birth rate for this group has risen from 7.48 percent (compared with the overall rise of 8.4 to 10.2 percent) with nearly all the increase among moderately preterm births; the percent of very pretem singletons increased only from 1.12 to 1.15 percent (57).

Figure 6. Rate of preterm birth by plurality and race and Hispanic origin of mother: United States, 1989-98

The preterm rate for non-Hispanic black births of all pluralities was unchanged at 17.6 percent for 1998. Among singleton biths only, however, the preterm rate declined from 16.23 to 16.15 percent between 1997 and 1998 (tigure 6). Most of the decline was for very preterm singleton births (from 3.72 to 3.66 percent); the rate for moderately pretem singleton biths was essentially unchanged. Since 1989 the non-Hispanic black preterm singleton birth rate is down from 18.03 percent, and very preterm singleton biths from 4.29 percent.

The proportion of Hispanic births bom preterm rose from 11.2 to 11.4 percent between 1997 and 1998; the bulk of the increase was for moderately preterm births. (Relative trends in preterm rates for Hispanic births were largely unaffected by trends in multiple births.) The pretem rate for Hispanic births has fluctuated around 11 percent during the 1990's. Small increases, both for the current year and since 1989, were found for each of the Hispanic subgroups. (See table $\mathbf{2 5}$ for 1998 data.)

## Birthweight

The rate of low blrthweight (LBW) (less than 2,500 grams) rose from 7.5 to 7.6 percent for 1997-98. The proportion of LBW births has risen slowly from the low of 6.7 reported in 1984, and is currently at levels as high as those reported in the early 1970's. (See tables 43-47 and figure 7.) The percent very low birthwelght (VLBW) (less than 1,500 grams) was 1.45 percent for 1998, up slightly from 1.42 percent reported for 1997. The rate of VLBW has also increased over the last two decades (from 1.13 percent in 1977). LBW infants, especially VLBW infants, are at greater risk than heavier babies of long-tem morbidity and early death (58). For 1997, VLBW infants comprised 51 percent of all those who did not survive the first year of life; moderately LBW infants, those weighing between 1,500 and 2,499 grams, accounted for an additional 14 percent of infant deaths (56).

The increase in the proportion of twins and triplets, because of their much higher risk of LBW, is continuing to have an important impact on overall trends in LBW. All of the increase in LBW between 1997 and 1998 is attributable to the rise in the proportion of multiple births and

NOTES: Low birthweight is less than 2,500 grams. Percents are plotted on a log scale. Hispanic includes persons of Hispanic Origin of any race.
e 7. Percent low birthweight by race and Hispanic l of mother: United States, 1970-98
to a small increase (1 percent) in LBW among multiple births. (For 1998, 56.9 percent of multiples were LBW compared with 6.1 percent of singletons.) Among singletons only, low birthweight was down slightly for 1997-98, from 6.08 to 6.05 percent. Since 1989 overall LBW has risen 9 percent, but LBW among singletons has risen by less than 1 percent (from 6.0 percent). See table $\mathbf{H}$.

Overall low birthweight increased slightly between 1997 and 1998 among non-Hispanic white (from 6.5 to 6.6 percent) and non-Hispanic black births (from 13.1 to 13.2 percent), and was unchanged for Hispanic births ( 6.4 percent). All of the increase in LBW among the former two groups for the current year is attributable to the rise in multiple births. Singleton LBW declined very slightly among both non-Hispanic white and non-Hispanic black biths from 4.95 to 4.91 and 11.46 to 11.44 percent, respectively).

In recent years, the rise in multiple birth rates has especially influenced LBW levels among non-Hispanic white births. Since 1989 overall LBW for this group has risen 18 percent (from 5.6 percent), but singleton LBW has risen a more modest 7 percent (see table H). Singleton non-Hispanic white VLBW was essentially unchanged for 1997-98 at 0.81 percent.

Among non-Hispanic black biths, singleton LBW has declined from 12.2 to 11.4 percent between 1989 and 1998, a somewhat steeper decline than is observed for all births ( 13.6 to 13.2 percent). However, the percent of singleton VLBW non-Hispanic black births has not improved over this period, hovering at about 2.6 percent, a level approximately three times as high as that of non-Hispanic white ( 0.81 percent) and Hispanic births ( 0.94 percent).

Overall and singleton LBW among Hispanic births has been comparatively stable during the 1990's. Levels for all pluralities have risen slightly from 6.2 to 6.4 percent; the singleton rate was essentially unchanged at 5.4 percent. The percent VLBW for all Hispanic births has risen slightly during the 1990's from 1.05 to 1.15 for 1989-98. As in previous years, the risk of LBW varied among the Hispanic subgroups for 1998. Levels ranged from 6.0 percent for Mexican, to 9.7 percent for Puerto Rican infants. (See table 25.)

The 1998 incidence of low birthweight among American Indian Infants was 6.8 percent, unchanged from 1997. There were no notable

Table H. Percent low birthweight among singletons by race and Hispanic origin of mother: United States, 1989-98

Figure 8. Percent low birthweight for all births and for singleton births only, by age of mother: United States, 1998
changes in LBW for the Asian or Pacific Islander subgroups; levels ranged from 5.3 percent for Chinese to 8.2 percent for Filipino biths (table 24).

Age-specific low birthweight rates for all pluralities follow a $U$-shaped pattem with levels slighty higher among older mothers. This pattem is strongly influenced, however, by the higher multiple birth rates of older women. For example, the overall percent LBW for women aged 45-54 years was 18.6 percent for 1998, by far the highest age-specific rate reported. When only singleton bitths are examined however, the LBW rate for this age group drops to 9.7 percent, substantially lower than the rate of 12.6 percent reported for teenagers under 15 years of age. (See flgure 8.)

The percent macrosomla (birthweight of at least 4,000 grams) was 10.1 for 1998, the same level reported for 1997. The percent of macrosomic biths peaked at about 11 during the 1980's, but has generally declined in the 1990's.

The medlan blithweight for all births for 1998 was 3,350 grams ( 7 pounds, 7 ounces), unchanged since 1995. The median for white biths was 3,390 grams, and for black births 3,180 grams.

As in previous years, LBW and VLBW rates varied quite widely by State for 1998. Among non-Hispanic white births, LBW levels ranged from a low of 5.1 percent in Oregon to a high of 8.9 percent for Wyoming. Among States with at least 1,000 births to non-Hispanic black mothers, LBW rates for this population ranged from 9.8 percent in Washington State to 15.9 percent in the District of Columbia (table 46).

## Apgar score

The Apgar score was developed by the late Virginia Apgar, M.D., as a means of evaluating the physical condition of newboms shortly after delivery (59). The score considers five characteristics of the baby that are easily identifiable-heart rate, respiratory effort, muscle tone, reflex iritability, and color. Each of these characteristics is assessed and assigned a value of 0 to 2 , with 2 being optimum. The total score is the sum of the scores of the five components and a score of 7 or greater indicates that the baby is in good to excellent physical condition. The 5 -minute Apgar score is based on an assessment at 5 minutes after delivery and is used to predict the newbom's chance of survival.

In 1998 all States except Califomia and Texas collected information on the 5 -minute Apgar score. Births to residents of these States unted for 78 percent of all births in the U.S. Only 1.4 percent of
babies had Apgar scores that were considered low (less than 7) at 5 minutes after bith, unchanged since 1993 (tables 24 and 25).

Of the major racial and ethnic groups, Asian or Pacific Islander babies as a group were in the best physical condition shortly after delivery-only 1.1 percent had scores of less than 7 (table 23). This was particularly true for Japanese and Chinese babies- -0.7 percent had low 5 -minute scores. The percent of babies with low scores was intermediate for non-Hispanic white and Hispanic women (1.3 and 1.2 percent, respectively) while 2.4 percent of non-Hispanic black babies had low 5 -minute scores.

## Abnormal conditions of the newborn

Of the eight specific abnormal conditions reported on the bith certificate, the rates per 1,000 live births in 1998 were highest for assisted ventilation less than 30 minutes ( 22 per 1,000 ), assisted ventilation 30 minutes or longer ( 9 per 1,000 ), and hyaline membrane disease/respiratory distress syndrome (RDS). ( 6 per 1,000 ) (table 48). It has been shown that these conditions may be underreported on the bith certificate (54).

## Congenital anomalies

In 1998 congenital anomalies were reported on the bith certificates of the District of Columbia and all States except New Mexico. These areas included 99 percent of births in the United States. Several studies have shown that congenital anomalies are underreported on the birth certificate ( $54,60,61$ ). For example, a recent study based on surveillance data estimated that there are about 4,000 cases of spina bifida and anencephalus each year in the United States; birth certificate data for 1998 identified a total of only 1,236 cases for these two neural tube defects (61).

Because many of the congenital anomalies tracked on bith certificates occur infrequently, the rates shown in this report are calculated per 100,00 live births (table 49). Caution should be used in comparing yearly rates for a specific anomaly as a small change in the number of anomalies reported can result in a relatively large change in rates.

## Multiple births

The number of births in twin delliverles rose 6 percent for 1997-98, to 110,670 biths, the largest single-year rise in several decades. The number of triplet bliths climbed to 6,919, a rise of 13 percent. Biths in quadruplet deliveries increased from 510 to 627 between 1997 and 1998; the number of quintuplet and other higher order multiples was unchanged at 79 . (See table J and table 50 .) Since 1980 twin biths have risen 62 percent (from 68,339 ) and triplet and other higher order multiple births (heretofore referred to as triplet+) have jumped 470 percent (from 1,337 ).

The twin blith rate (the number of twin births per 1,000 live births) rose 5 percent for the current year to 28.1 (or 2.8 percent of all births). The triplet/+ blith rate (the number of triplet, quadruplet, and quintuplet and other higher-order multiples per 100,000 live biths), jumped 11 percent for 1998, to 193.5 per 100,000 (or 0.2 percent of births). Both twin and triplet+ birth rates have risen steadily since 1980 , by 49 and 423 percent respectively (62), but the pace of the increase has quickened in the 1990's (figure 9). Between 1990 and 1998, the twinning rate has risen about 3 percent per year, and the triplet/+ rate an average of

Table J. Numbers of twin, triplet, quadruplet, and quintuplet and other higher order multiple births: United States, 1989-98

| Year | Twins | Triplets | Quadruplets | Quintuplets and other higher order multiples' |
| :---: | :---: | :---: | :---: | :---: |
| 1998 | 110,670 | 6,919 | 627 | 79 |
| 1997 | 104,137 | 6,148 | 510 | 79 |
| 1996 | 100,750 | 5,298 | 560 | 81 |
| 1995 | 96,736 | 4,551 | 365 | 57 |
| 1994 | 97,064 | 4,233 | 315 | 46 |
| 1993 | 96,445 | 3,834 | 277 | 57 |
| 1992 | 95,372 | 3,547 | 310 | 26 |
| 1991 | 94,779 | 3,121 | 203 | 22 |
| 1990 | 93,865 | 2,830 | 185 | 13 |
| 1989 | 90,118 | 2,529 | 229 | 40 |

'Quintuplets, sextuplats, and higher order muftiple births are not differentiated in the national data set.

13 percent annually. In 1998, one in every 36 births was a twin; almost one in every 500 births was a triplet/t.

The recent rise in multiple biths has been especially pronounced among women 30 years of age and over. Between 1980-82 and 1996-98 (data for 3 years are combined to generate more statistically reliable rates) the twin bith rate increased 77 percent among women aged $40-44$ years (from 21.6 to 38.2 per 1,000 ), and by more than 1,000 percent among women $45-49$ years of age (from 10.8 to 129.9). The triplet/+ bith rate rose 461 percent for women in their thirties ffrom 59.3 to 332.4 per 100,000 ), and almost 15 times for women in their forties (from 28.1 to 411.9). In contrast, among women aged 20-24 years, twin birth rates rose a comparatively modest 18 percent and triplet bith rates by 53 percent over this time period (62).

Two related trends have been associated with the rise in multiple births, especially with the rise of higher order multiples; older age at childbearing (women in their thirties are more likely than younger women to have a multiple birth, even without the use of fertility therapy), and the more widespread use of fertility-enhancing therapies (fertility drugs and techniques such as in vitro fertilization). These therapies have been associated with the remarkable upswing in multiple births of the 1980's and 1990's (63-65). A recent study estimates that about 80

Figure 9. Triplet/+ birth rates by race and Hispanic origin -6-7ther, 1980-98
percent of triplet/+ births in 1996 and 1997 were the result of fertility techniques (66).

Twinning rates rose 4 to 5 percent among the three largest U.S. racial and ethnic groups for 1997-98, but continue to be slightly higher among non-Hispanic black (31.3) compared with non-Hispanic white (30.2) women. The Hispanic twin bith rate continued to be substantially lower (20.4) than both. Most of the overall increase in the triplett+ rate was the result of a sizable 14 percent rise among non-Hispanic white women (from 230.8 to 262.8 per 100,000); levels among other groups changed only slightly. Rates have risen substantially for all groups over the past two decades, but the largest increase has been observed among triplet/+ births to white mothers. In 1998 the triplet/+ birth rate for non-Hispanic white women (262.8) was 3 times as high as that for non-Hispanic black women (87.3), and Hispanic women (75.3). This differential is likely associated with the older age at childbearing of non-Hispanic white women compared with their black and Hispanic counterparts, and with their wider use of infertility services (16).

Currently, multiple birth rates rise with increasing maternal age until age group 35-39 years, dip slightly for women aged 40-44 years, and then peak sharply for women aged $45-54$ years. This is a change from earlier years when rates were highest among women aged 35-39 years (62). In 1998 one of every six births to women aged 45-49 years and one in three births to women 50-54 years was a twin or triplet't.

Multiple births are at greater risk than singletons of being bom too early and too small and, accordingly, of not surviving the first year of life. For 1998, 41.7 percent of twins, and 89.1 percent of triplet/+ were bom both preterm and LBW, compared with 3.8 percent of singletons. The increase in the multiple birth rate because of their higher levels of risk is having an important impact on these basic measures of national and state perinatal health $(57,67)$. For example, the overall U.S. level of LBW was up for 1998, but LBW among singleton biths only, was slightly lower. (See sections on birthweight and period of gestation.)

## List of tables

1. Live births, birth rates, and ferility rates, by race: United States, specified years 1940-55 and each year, 1960-98
2. Live births by age of mother, live-birth order, and race of mother: United States, 1998
3. Fertility rates and birth rates by age of mother, live-birth order, and race of mother: United States, 1998
4. Total fertility rates and birth rates by age of mother: United States, 1970-98, and by age and race of mother: United States, 1980-98.
5. Fertility rates and birth rates by live-birth order and race of mother: United States, 1980-98
6. Live births, birth rates, and fertility rates, by Hispanic origin of mother and by race for mothers of non-Hispanic origin: United States, 1989-98
7. Live births by age of mother, live-birth order, Hispanic origin of mother, and by race for mothers of non-Hispanic origin: United States, 1998
8. Fertility rates and birth rates by age of mother, live-birth order, Hispanic origin of mother, and by race for mothers of nonHispanic origin: United States, 1998
9. Total fertility rates, ferilitity rates, and birth rates by age and Hispanic origin of mother and by race for mothers of nonHispanic origin: United States, 1989-98
10. Number of births, birth rates, fertility rates, total fertility rates, and birth rates for teenagers $15-19$ years by age of mother: United States, each State and territory, 1998
11. Live births by race of mother: United States, each State and territory, 1998.
12. Live births by Hispanic origin of mother and by race for mothers of non-Hispanic origin: United States, each State and ternitory, 1998
13. Total number of births, rates, and percent of births with selected demographic characteristics, by specified race of mother and place of bith of mother: United States, 1998
14. Total number of births, rates, and percent of births with selected demographic characteristics, by Hispanic origin of mother and by race for mothers of non-Hispanic origin and by place of birth of mother: United States, 1998.
15. Live births by race of mother and observed and seasonally adjusted birth and fertility rates, by month: United States, 1998
16. Live births by day of week and index of occurrence by method of delivery, day of weak, and race of mother: United States, 1998
17. Number, rate, and percent of births to unmarried women by age, race, and Hispanic origin of mother: United States, 1998
18. Birth rates for unmarried women by age of mother: United States, 1970, 1975, and 1980-98, and by age, race, and Hispanic origin of mother: United States, 1980-98
19. Number and percent of births to unmarried women by race and Hispanic origin of mother: United States, each State and territory, 1998
20. Birth rates by age and race of father: United States, 1980-98.
21. Live births by educational attainment, and percent of mothers completing 12 years or more and 16 years or more of school, by age and race and Hispanic origin of mother: United States, 1998
22. Number of live births and percent distribution by weight gain of mother during pregnancy and median weight gain, according to period of gestation, race, and Hispanic origin of mother: Total of 49 reporting States and the District of Columbia, 1998
23. Percent low birthweight by weight gain of mother during pregnancy, period of gestation, and race and Hispanic origin of mother: Total of 49 reporting States and the District of Columbia, 1998
24. Percent of births with selected medical or health characteristics, by specified race of mother, by place of birth of mother: United States, 1998
25. Percent of births with selected medical or health characteristics, by Hispanic origin of mother and by race for mothers of non-Hispanic origin and by place of birth of mother: United States, 1998
26. Live births to mothers with selected medical risk factors and rates by age of mother, by race of mother: United States, 1998
27. Number and rate of live births to mothers with selected medical risk factors, complications of labor, and obstetric procedures, by specified race of mother: United States, 1998
28. Number and rate of live births to mothers with selected medical risk factors, complications of labor, and obstetric procedures, by Hispanic origin of mother and by race for mothers of nonHispanic origin: United States, 1998
mother: Total of 46 reporting States, the District of Columbia, and New York City, 1998
29. Number of live births by smoking status of mother and percent of mothers who smoked cigarettes during pregnancy, by age and Hispanic origin of mother and by race for mothers of non-Hispanic origin: Total of 46 reporting States, the District of Columbia, and New York City, 1998.
30. Number of live births, percent of mothers who smoked cigarettes during pregnancy, and percent distribution of average number of cigarettes smoked by mothers per day, according to educational attainment and race and Hispanic origin of mother: Total of 46 reporting States, the District of Columbia, and New York City, 1998
31. Percent low birthweight by smoking status, age, and race and Hispanic origin of mother: Total of 46 reporting States, the District of Columbia, and New York City, 1998.

61
33. Live births by month of pregnancy prenatal care began and percent of mothers beginning care in the first trimester and percent with late or no care, by age and race and Hispanic origin of mother: United States, 1998
34. Percent of mothers beginning prenatal care in the first trimester and percent of mothers with late or no prenatal care by race and Hispanic origin of mother: United States, each State and territory, 1998
35. Live births by month of pregnancy prenatal care began, number of prenatal visits, and median number of visits, by race and Hispanic origin of mother: United States, 1998
36. Live births to mothers with selected obstetric procedures and rates by age of mother, by race of mother: United States, 1998

67
37. Live births to mothers with selected complications of labor and/or delivery and rates by age of mother, by race of mother: United States, 1998
38. Live births by attendant, place of delivery, and race and Hispanic origin of mother: United States, 1998.

69
39. Live births by method of delivery and rates of cesarean delivery and vaginal birth after previous cesarean delivery, by race and Hispanic origin of mother: United States, 1989-98
40. Live births by method of delivery, and rates of cesarean delivery and vaginal birth after previous cesarean delivery, by age and race and Hispanic origin of mother: United States, 1998.
41. Rates of cesarean delivery and vaginal birth after previous cesarean delivery by race and Hispanic origin of mother: United States, each State and territory, 1998
42. Rates of cesarean delivery and vaginal birth after previous cesarean delivery, by selected maternal modical risk factors and complications of labor and/or delivery: United States, 1998 .
43. Live births by birthweight and percent very low and low birthweight, by period of gestation and race and Hispanic origin of mother: United States, 1998.
44. Percent of live births very preterm and preterm and percent of live births of very low birthweight and low birthweight, by race and Hispanic origin of mother: United States, 1981-98 . . . . . .
45. Number and percent low birthweight and number of live births by birthweight, by age and race and Hispanic origin of mother: United States, 1998
46. Number and percent of births of low birthweight by race and Hispanic origin of mother: United States, each State and territory, 1998
47. Number and percent of births of very low birthweight by race and Hispanic origin of mother: United States, each State and territory, 1998
48. Live births with selected abnormal conditions of the newborn and rates by age of mother, by race of mother: United States, 1998
49. Live births with selected congenital anomalies and rates by age of mother, by race of mother: Total of 49 reporting States and the District of Columbia, 1998 . . . . . . . . . . . . . . . . . . . . . . . . 50. Live births by plurality of birth and ratios, by age and race and Hispanic origin of mother: United States, 1998

24 National Vital Statistics Report, Vol. 48, No. 3, March 28, 2000
Table 1. Live births, birth rates, and fertility rates, by race: United States, specified years 1940-55 and each year, 1960-98
[Birth rates are live births per 1,000 population in specified group. Fertility rates per 1,000 women aged 15-44 years in specified group. Population enumerated as of April 1 for census years and estimated as of July 1 for all other years. Beginning with 1970, excludes births to nonresidents of the United States]

*Figure does not meet standards of rellability or precision; based on tewer than 20 births in numerator.
0.0 Quantity more than zero but less than 0.05

1 Rates computed by relating total biths, regardless of age of mother, to women aged 15-44 years.
2 Rates computed by relating births to women aged $45-54$ years to women aged $45-49$ years.
3 Includes births to Aleuts and Eskimos.

Table 4. Total fertility rates and blith rates by age of mother: United States, 1970-98, and by age and race of mother: United States, 1980-98

TTotal fertility rates are sums of birth rates for 5 -year age groups multiplied by 5 . Birth rates are live births per 1,000 women in specitied group, enumerated as of April 1 for 1970, 1980, and 1990, and estimated as of July 1 for all other years]

| Year and race | Total fertility rate | Age of mother |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

[^3]NOTE: Race and Hispanic origin are reported separately on birth certificates. In this table all women (inciuding Hispanic women) are classified only according to their race; see Technical notes.

Table 5. Fertility rates and birth rates by live-birth order and race of mother: United States, 1980-98
[Rates are live births per 1,000 women aged 15-44 years, enumerated as of April 1 for 1980 and 1990, and estimated as of July 1 for all other years. Figures for live-birth order not stated are distributed]

- Figure does not meet standards of reliability or precision; based on fower than 20 births in the numerator.
0.0 Quantity more than zero but less than 0.05 .
0.0 Quantity more than zero but less than 0.05 .
1 Rates computed by relating total births, regardiess of age of mother, to women aged 15-44 years.

1 Rates computed by relating total biths, regardiess of age of mother, to women aged 15-44 y
2 Rates computed by relating births to women aged 45-54 years to women aged 45-49 years.
2 Rates computed by relating births to women aged 45-54 years to women
3 Includes Central and South
5 Includes races other than white and black.
NOTE: Race and Hispanic origin are reported separately on birth certificates. Persons of Hispanic origin may be of any race. In this table Hispanic women are classified only by place of origin; non-Hispanic women are classifled by race. See Technical notes.

Table 9. Total fertility rates, fertility rates, and birth rates by age and Hispanic origin of mother and by race for mothers of non-Hispanic origin: United States, 1989-98
[Total fertility rates are sums of birth rates for 5 -year age groups multiplied by 5 . Birth rates are live births per 1,000 women in specified group, enumerated as of April 1 for 1990, and estimated as of July 1 for all other years]

- Figure does not meet standards of reliablity or prectsion; based on fewer than 20 births in the numerator.
-. Data not available.
.0 Quantity more than zero but less that 0.05 .
1 Rates computed by relating total births, regardless of age of mother, to women 15-44 years.
${ }_{3}$ Beginning 1997, reles computed by relating births to women aged $45-54$ years to women aged $45-49$ years.
${ }_{4}$ Excludes data for Now Hampshire, which did not report Hispanic orgin.
${ }_{5} 5$ Excludes data for Now Hampshire and Oxlahoma, which did not report Hispanic origin.
5 Excludes data for Louislana, Now Hampshire, and Oklahoma, which did not report Hispanic origin.
6 includes Central and South American and other and unknown Hispanic.
7 includes origin not stated.
8 Includes races other than white and black.
NOTE: Race and Hispanic origin are reported separately on birth certificates. Persons of Hispanic origin may be of any race. In this table Hispanic women are classifled only by place of orgin; non-Hispanlc women are classified by race. See Technical noles.

Table 10. Number of births, birth rates, fertility rates, total fertility rates, and birth rates for teenagers 15-19 years by age of mother: United States, each State and territory, 1998
[By place of residence. Birth rates per 1,000 estimated population in each area; fertility rates per 1,000 women aged 15-44 years estimated in each area: total fertility rates are sums of birth rates for 5-year age groups multiplied by 5: birth rates by age are live births per 1,000 women in specified age group estimated in each areal

-- Data not avaiiable.
1 Includes races other than white and black and origin not stated.
2 Includes all persons of Hispanic origin of any race.
3 Rates computed by relating total births to unmarried mothers, regardless of age of mother, to unmarried women aged 15-44 years.
4 Pates computed by relating births to unm arried mothers aged 40 years and over to unmarried women aged $40-44$ years.
NOTES: For 48 States and the District of Columbia, marital status is reported on the birth certficate; for Michigan and New York, mother's marital status is inferred; see Technical notes. Rates cannot be computed for unmarried non-Hispanic black women because the necessary populations are not available.

Table 18. Birth rates for unmarried women by age of mother: United States, 1970, 1975, and 1980-98, and by age, race, and Hispanic origin of mother: United States, 1980-98
[Rates are live biths to unmamied women per 1,000 unmarried women in specitied group, estimated as of July 1]

-- Data not avallable.
1 Rates computed by relating total births to unmarrled mothers, regardess of age of mother, to unmarried women aged 15-44 years.
2 Rates computed by relating blths to unmarried mothers aged 40 years and over to unmarried women aged $40-44$ years.
3 Includes races other than white and black
4 Data for States in which marital status was not reported have been inferred and included with data from the remalning States; see Technical notes.
5 Based on 100 percent of blths in selected States and on a 50 -percent sample of biths in all other States; see Technical notes.
5 Based on 100 percent of births in selected States and on a 50 -percent sample of births in all other States; see Technical notes.
6 Births to unmarried women are estlmated
8 Rates for 1990 based on data for 48 States and the District of Columbla which reported Hispanic origin on the birth certificate. Rate shown for ages $35-39$ years is based on births to unmarried women agad $35-44$ years.
9 Includes all persons of Hispank origin of any race.
NOTE: Rates cannot be computed for unmarried non-Hispanic black women because the necessary populations are not avallable.

Table 19. Number and percent of births to unmarried women by race and Hlspanic origin of mother: United States, each State and territory, 1998
[By place of residence]

| State | Births to unmarried women |  |  |  |  |  | Percent unmarried |  |  |  |  |  |

* Figure does not meet standards of rellablility or precision; based on fewer than 20 births in the numerator or denominator.
- Data not avallable.

1 Percent of all live births by cesarean delivery.
2 Percent of aill ive births by cesarean deivery.
3 Number of vaginal births after previous cesarean delivery per 100
4 Includes races other than white and black and origin
Excludes data for the territorles.
NOTE: Data on method of delvery for the Northem Marianas are substantlaily Incomplete; see Table I In the Technical notes.

Table 42. Rates of cesarean delivery and vaginal birth after previous cesarean delivery, by selected maternal medical risk factors and complications of labor and/or delivery: United States, 1998

## Technical notes

## Source of data

Data shown in this report for 1998 are based on 100 percent of the birth certificates in all States and the District of Columbia. The data are provided to the National Center for Health Statistics (NCHS) through the Vital Statistics Cooperative Program (VSCP). In 1984 and earlier years, the VSCP included varying numbers of States that provided data based on 100 percent of their bith certificates. Data for States not in the VSCP were based on a 50 -percent sample of birth certificates filed in those States. Information on sampling procedures and sampling errors for 1984 and earlier years is provided in the Technical Appendix, Vital Statistics of the United States, 1997, Volume I, Natality (3). Information on the percent of records with missing information for matemal and infant characteristics included in this report is shown by State in table I. Data are not shown for the variables race, age, and marital status of mother. Missing data are imputed in these cases; see separate sections in the Technical notes for more information.

## Age of mother

Age of mother is computed in most cases from the mother's and infant's dates of bith as reported on the bith certificate. The mother's age is directly reported by five States (Kentucky, Nevada, North Dakota, Virginia, and Wyoming) and American Samoa. From 1964 to 1996, mother's age was edited for ages outside the age range 10-49 years. Births reported to occur to mothers younger than age 10 or older than age 49 years had age imputed according to the age of mother from the previous record with the same race and total birth order (total of live births and fetal deaths). Beginning in 1997, age of mother is edited for ages outside the age range $10-54$ years (3). A review and verification of unedited birth data for 1996 showed that the vast majority of births reported as occurring to women aged 50 years and over were to women aged $50-54$ years. The numbers of births to women aged $50-54$ years are too small for computing age-specific birth rates. These births have been included with births to women aged 45-49 years for computing bith rates.

In 1998 age of mother was not reported on 0.02 percent of the records; for these records age of mother was imputed according to the last record with the same race and total bith order.

## Race and Hispanic origin

Race and Hispanic origin are reported separately on the birth certificate. Beginning with the 1989 data year, NCHS started tabulating its bith data primarily by race of the mother. Birth data published for 1988 and prior years showed biths tabulated by the race of the child, which was determined from the race of the parents as entered on the birth certificate.

Trend data by race shown in this report are by race of mother for all years beginning with the 1980 data year; data for 1980-88 that were previously published by race of child have been re-tabulated by race of mother. In order to facilitate continuity and analysis of the data, trend tables showing data for years prior to 1980 show data for both. race of mother and race of child for 1980. This makes it possible to distinguish the effects of this change from real changes in the data. The text
sions of data by race are based on tabulations by race of mother.

Text references to white births and white mothers or black births and black mothers are used interchangeably for ease in writing.

The factors influencing the decision to tabulate births by race of the mother have been discussed in detail elsewhere (67). They include the 1989 revision of the bith certificate, which includes many more health questions that are directly associated with the mother. In these instances, it is more appropriate to tabulate biths by the mother's race. Another factor influencing the decision to tabulate births by race of mother is the large proportion of births with race of father not stated, 14 percent in 1998. Although this proportion has declined slightly in the 1990's, it is still higher than in 1978, 11 percent. The high proportion of records with the father's race not reported reflects the increase in the proportion of biths to unmarried women; in many such cases, no information is reported on the father. These biths are already assigned the race of the mother because there is no altemative. Tabulating all births by race of mother, therefore, provides for a more uniform approach, rather than a necessarily arbitrary combination of parental races.

Race of mother is reported by all registration areas in eight categories: white, black, American Indian, Chinese, Japanese, Hawaiian, Filipino, and "other" Asian or Pacific Islander (API). In addition, nine States (Califomia, Hawaii, Illinois, Minnesota, New Jersey, New York, Texas, Virginia, and Washington) report data on API subgroups included in the "other" API category (Vietnamese, Asian Indian, Korean, Samoan, Guamanian, and remaining API). A report on births in 1992 to women in these API subgroups has been published (68).

In 1998 race of mother was not reported for 0.8 percent of births. In these cases, if the race of the father was known, the race of the father was assigned to the mother. When information was not available for either parent, the race of the mother was imputed according to the specific race of the mother on the preceding record with a known race of mother. This was necessary for just 0.4 percent of births in 1998.

Hispanic origin and race are reported independently on the bith certificate, as noted previously. Data for Hispanic subgroups are shown in most cases for five groups: Mexican, Puerto Rican, Cuban, Central and South American, and other and unknown Hispanic. In tabulations of bith data by race only, data for persons of Hispanic origin are included in the data for each race group according to the mother's reported race. In tabulations of birth data by race and Hispanic origin, data for persons of Hispanic origin are not further classified by race because the vast majority of births to Hispanic women are reported as white. In these tabulations, data for non-Hispanic persons are classified according to the race of the mother because there are substantial differences in fertility and matemal and infant health between Hispanic and non-Hispanic white women.

Items asking for the Hispanic origin of the mother and the father have been included on the birth certificates of all States and the District of Columbia, the Virgin Islands, and Guam since 1993 (4). Puerto Rico, American Samoa, and the Northem Marianas do not collect this information. The percent of records for which Hispanic origin of the parents was not reported in 1998 is shown by State in table I.

## Marital status

National estimates of births to unmarried women are based on two methods of determining marital status. For 1994 through 1996, birth certificates in 45 States and the District of Columbia included a question about the mother's marital status. In 1997 California added a

| Area | Number of births | $\begin{gathered} \text { Place } \\ \text { of } \\ \text { birth } \end{gathered}$ | Attendant at birth | Mother's birthplace | Father's age | Father's race | Hispanic origin |  | Educational attainment Mother | Livebith order | Length of gestation | Month prenatal care began | Number of prenatal visits |

direct question to their birth certificate; thus by 1997, all but four States (Connecticut, Michigan, Nevada, and New York) included a direct question on their birth certificates. Nevada asks for the mother's marital status through the electronic birth registration process but this item is not included on certified or paper copies of the bith certificate. Beginning June 15, 1998, Connecticut discontinued infering the mother's marital status and added a direct question on mother's mantal status to the State's bith certificate.

In the two States (Michigan and New York) that use inferential procedures to compile birth statistics by marital status in 1998, a birth is inferred as nonmarital if either of these factors is present: a patemity acknowledgment was received or the father's name is missing. In recent years, a number of States have extended their efforts to identify the fathers when the parents are not married in order to enforce child support obligations. The presence of a paternity acknowledgment therefore is the most reliable indicator that the birth is nonmarital in the States not reporting this information directly; this is now the key indicator in the nonreporting States.

Since 1980 the National Center for Health Statistics has published information on nonmarital births, which incorporates reported and inferential data. The inferential procedures represent a substantial departure from the method used before 1980 to prepare national estimates of births to unmarried women, which assumed that the incidence of biths to unmarried women in States with no direct question on marital status was the same as the incidence in reporting Slates in the same geographic division (23). Inferential procedures in current use, however, are quite different from those in use during the 1980's, when there was heavy reliance on a comparison of the sumames of the parents and the child to infer the mother's marital status. The procedures now in use depend, as noted above, on very reliable indicators, namely a patemity affidavit or missing information on the father.

A review of Connecticut's birth data for 1998 indicate that during the first 6 months of 1998, when the inferential procedures were still in use, the proportion of biths to unmarried women was somewhat higher ( 33 percent) than in the last 6 months when marital status was based on a direct question ( 29 percent). The inferential procedures in effect in Connecticut relied principally on a comparison of the sumames of the parents and child. It appears that the inferential procedures resulted in some overestimation of the number of biths to unmaried women, probably because of the reliance on a comparison of sumames. It is estimated that if the Connecticut reporting procedures had not changed, the number of nonmarital births would have been about 1,000 higher. Because Connecticut accounts for only about 1 percent of U.S. births, the reporting changes had essentially no impact on data for the Nation.

The procedures for reporting marital status in Califomia, Nevada, and New York City changed beginning January 1, 1997. The methods used to determine marital status and the impact of the procedures on the data were discussed in detail in previous reports ( 1,20 ).

The use of inferential marital status data together with information from a direct question represents an attempt to use related information on the birth cerificate to improve the quality of national data as well as to provide data for the individual nonreporting States. Because of the continued substantial increases in nonmarital childbearing throughout the 1980's, the data have been intensively evaluated by the Division of Vital Statistics, NCHS. The results of this evaluation show that trends in hith rates for unmaried women for rates computed on the basis of
estimated data and on the basis of inferred data are essentially the same.

The mother's marital status was not reported in 1998 on 0.04 percent of the birth records. Marital status was imputed as "married" for these records.

## Prenatal care

As a result of a programming error, the proportions presented in "Report of Final Natality Statistics, 1996" and "Births: Final Data for 1997" for the Adequacy of Prenatal Care Ubilization Index (APNCU) are incorrect for levels of care other than intensive use of care (19, 20,71). Levels for the adequate care category are only slightly different from those published previously. The corrected APNCU levels for 1990 and 1995-97 are presented in this report.

## Gestation

The primary measure used to determine the gestational age of the newborn is the interval between the first day of the mother's last nomal menstrual period (LMP) and the date of birth. It is subject to error for several reasons, including imperfect maternal recall or misidentification of the LMP because of postconception bleeding, delayed ovulation, or intervening early miscarriage. These data are edited for LMP-based gestational ages that are clearly inconsistent with the infant's plurality and bithweight (see below), but reporting problems for this item persist and may occur more frequently among some subpopulations and among births with shorter gestations (70, 72).

The U.S. Standard Cerificate of Live Birth includes an item, "clinical estimate of gestation," that is being compared with length of gestation computed from the date the last normal menstrual period (LMP) began when the latter appears to be inconsistent with birthweight. This is done for normal weight births of apparently short gestations and very low birthweight births reported to be full term. The clinical estimate was also used if the LMP date was not reported. The period of gestation for 5.1 percent of the biths in 1998 was based on the clinical estimate of gestation. For 97 percent of these records, the clinical estimate was used because the LMP date was not reported. For the remaining 3 percent, the clinical estimate was used because it was compatible with the reported birthweight, whereas the LMP-based gestation was not. In cases where the reported birthweight was inconsistent with both the LMP-computed gestation and the clinical estimate of gestation, the LMP-computed gestation was used, and bithweight was reclassified as "not stated." This was necessary for about 350 biths, or 0.01 percent of all birth records in 1998. The levels of the adjustments in 1998 data were similar to those for 1997 and earlier years (20).

## Birthweight

Birthweight is reported in some areas in pounds and ounces rather than in grams. However, the metric system has been used in tabulating and presenting the statistics to facilitate comparison with data published by other groups. Equivalents of the gram weights in terms of pounds and ounces are as follows:

[^46]$1,500-1,999$ grams $=3 \mathrm{lb} 5 \mathrm{oz}-4 \mathrm{lb} 6 \mathrm{oz}$
$2,000-2,499$ grams $=4 \mathrm{lb} 7 \mathrm{oz}-5 \mathrm{lb} 8 \mathrm{oz}$
$2,500-2,999$ grams $=5 \mathrm{lb} 9 \mathrm{oz}-6 \mathrm{lb} 9 \mathrm{oz}$
$3,000-3,499$ grams $=6 \mathrm{lb} 10 \mathrm{oz}-7 \mathrm{lb} 11 \mathrm{oz}$
$3,500-3,999$ grams $=7 \mathrm{lb} 12 \mathrm{oz}-8 \mathrm{lb} 13 \mathrm{oz}$
$4,000-4,499$ grams $=8 \mathrm{lb} 14 \mathrm{oz}-9 \mathrm{lb} 14 \mathrm{oz}$
$4,500-4,999$ grams $=9 \mathrm{lb} 15 \mathrm{oz}-11 \mathrm{lb} 0 \mathrm{oz}$
5,000 grams or more $=11 \mathrm{lb} 1 \mathrm{oz}$ or more

## Method of delivery

Several rates are computed for method of delivery. The overall cesarean section rate or total cesarean rate is computed as the percent of all biths that were delivered by cesarean section. The primary cesarean rate is a measure that relates the number of women having a first cesarean delivery to all women giving bith who have never had a cesarean delivery. The denominator for this rate includes all births less those with method of delivery classified as repeat cesarean, vaginal birth atter previous cesarean, or method not stated. The rate for vaginal bith after previous cesarean (VBAC) delivery is computed by relating all VBAC deliveries to the sum of VBAC and repeat cesarean deliveries, that is, to women with a previous cesarean section. The proportion of VBAC deliveries among births in Hawaii in 1998 is overstated because of incomplete reporting in some hospitals.

## Computations of percents, percent distributions, and medians

Births for which a particular characteristic is unknown were subtracted from the figures for total births that were used as denominators before percents, percent distributions, and medians were computed. The percent of records with missing infomation for each item is shown by State in tablel. The median number of prenatal visits also excludes births to mothers who had no prenatal care. Computations of the median years of school completed and the median number of prenatal visits were based on ungrouped data. An asterisk is shown in place of any derived statistic based on fewer than 20 births in the numerator or denominator.

## Population denominators

Birth and fertility rates for 1998 shown in tables $1,3-6,8,9,13$, and 14 are based on populations estimated as of July 1,1998 . These populations are shown in tables II and III. The population estimates have been published by the U.S. Bureau of the Census (5) and are based on the 1990 census counts by race and age, which were modified to be consistent with Office of Management and Budget racial categories and historical categories for bith data, and in the case of age, to reflect age as of the census reference date. The modification procedures are described in detail in a census report (73).

Birth and fertility rates by State shown in table 10 are based on State-level population estimates provided by the U.S. Bureau of the Census that are consistent with the U.S. populations (74). Rates by State shown in this report may differ from rates computed on the basis of other population estimates. Birth and fertility rates by month shown in table 15 are based on monthly population estimates also based on . 38 estimates. Rates for unmarried women shown in tables 17 and

18 are based on distributions of the population by marital status as of March 1998 provided by the U.S. Bureau of the Census (22), which have been adjusted to July 1998 population levels (5) by the Division of Vital Statistics, NCHS (23).

Bith and fertility rates for the Hispanic population, shown in tables 6, 8, 9, and 14, are based on estimates of the total Hispanic population as of July 1, 1998 (5). Rates for Hispanic subgroups are based on special population estimates that are presented in table III in the Technical notes (75).

## Computation of rates

In computing birth rates by live-birth order, births with birth order not stated were distributed in the same proportion as bitths of known live-bith order. This procedure is done separately by race.

In computing bith and fertility rates for the Hispanic population, births with origin of mother not stated are included with non-Hispanic births rather than being distributed. Thus, rates for the U.S. Hispanic population are underestimates of the true rates to the extent that the births with origin of mother not stated ( 1.2 percent) were actually to Hispanic mothers (see table I). In computing the rates, the censusbased populations with origin not stated are imputed. The effect on the rates is believed to be small.

Age of father-Information on age of tather is often missing on birth certificates of children born to unmarried women (table I). In computing birth rates by age of father, births where age of father is not stated are distributed in the same proportions as births with known age within each 5 -year age classification of mother. This procedure is followed because, while father's age is missing on 14 percent of the bith certificates, one third of these were on records where the mother is a teenager. This distribution procedure is done separately by race. When the father's race is not stated, the race of the mother is assigned to the father prior to distributing the data for age of father not stated. The resulting distributions are summed to form a composite frequency distribution that is the basis for computing birth rates by age of father. This procedure avoids the distortion in rates that would result it the relationship between age of mother and age of father were disregarded.

## Graphic presentation

Trend data shown in figures 2-7 are plotted using a logarithmic scale. This approach is taken to facilitate comparison of the relative change in rates over time for each series of rates as well as the differentials among rates for different series. The trend lines in figure 2, for example, show that women 40-44 years of age experienced the most change of any group over the period, and also that they had the greatest increase in rates since 1985.

## Random variation and significance testing for natality data

The number of bitths reported for an area is essentially a complete count, because more than 99 percent of all biths are registered. Although this number is not subject to sampling error, it may be affected by nonsampling errors such as mistakes in recording the mother's residence or age during the registration process.

When the number of births is used for analytic purposes the number of events that actually occurred can be thought of as one in

Table II. Estimated total population by race, and estimated female population by age and race: United States, 1998 [Populations estimated as of July 1]

| Age | All races | White | Black | American Indian | Asian or Pacific Islander |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Total population | 270,298,524 | 223,000,729 | 34,430,569 | 2,359,946 | 10,507,280 |
| Female population |  |  |  |  |  |
| 15-44 years | 60,111,557 | 48,250,829 | 8,591,694 | 569,534 | 2,699,500 |

a large series of possible results that could have occurred under the same circumstances. When considered in this way, the number of biths is subject to random variation. The probable range of values may be estimated from the actual figures according to certain statistical assumptions.

The confidence interval is the range of values for the number of births, birth rates, or percent of births that you could expect in 95 out of 100 cases. The confldence limits are the end points of this range of values (the highest and lowest values). Confidence limits tell you how much the number of events or rates could vary under similar circumstances.

Confidence limits for numbers, rates, and percents can be estirom the actual number of events. Procedures differ for rates and
percents and also differ depending on the number of births on which these statistics are based. Below are detailed procedures and examples for each type of case.

## 95 -percent confidence limits for numbers less than 100

When the number of births is less than 100 and the rate is small, the data are assumed to follow a Poisson probability distribution. Confidence limits are estimated using the following formulas:

$$
\begin{aligned}
& \text { Lower limit }=B \times L \\
& \text { Upper limit }=B \times U
\end{aligned}
$$

where:
$B=$ the number of biths
$L=$ the value in Table IV that corresponds to the number $B$
$U=$ the value in Table IV that corresponds to the number $B$

## Example

Suppose that the number of first births to American Indian women $40-44$ years of age was 47 . The confidence limits for this number would be:

$$
\begin{aligned}
\text { Lower limit } & =B \times L \\
& =47 \times 0.73476 \\
& =35
\end{aligned}
$$

$$
\begin{aligned}
\text { Upper limit } & =B \times U \\
& =47 \times 1.32979 \\
& =63
\end{aligned}
$$

This means that the chances are 95 out of 100 that the actual number of first births to American Indian women 40-44 years of age would lie between 35 and 63.

## 95-percent confidence limits for numbers of 100 or more

When the number of events is greater than 100, the data are assumed to be approximately normally distributed. Formulas for 95-percent confidence limits are:

Lower limit $=B-(1.96 \times \sqrt{B})$
Upper limit $=B+(1.96 \times \sqrt{B})$
where:
$B=$ the number of biths

## Example

Suppose that the number of first births to white women 40-44 years of age was 14,108 . The 95-percent confidence limits for this number would be:

$$
\begin{aligned}
\text { Lower limit } & =14,108-(1.96 \times \sqrt{14,108}) \\
& =14,108-233 \\
& =13,875 \\
\text { Upper limit } & =14,108+(1.96 \times \sqrt{14,108}) \\
& =14,108+233 \\
& =14,341
\end{aligned}
$$

This means that the chances are 95 out of 100 that the actual number of first births to white women 40-44 years of age would lie between 13,875 and 14,341 .

## Computing confidence intervals for rates

The same statistical assumptions can be used to estimate the variability in birth rates. Again, one formula is used for rates based on numbers of events less than 100, and another formula for rates based on numbers of 100 or greater. For our purposes, assume that the denominators of these rates (the population estimates) have no error. RIC ${ }^{\text {this assumption is technically correct only for denominators }}$
based on the census that occurs every 10 years, the error in intercensal population estimates is usually small, difficult to measure, and therefore not considered.

## 95-percent confidence limits for rates based on less than 100 events

When the number of events in the numerator is less than 20, an asterisk is shown in place of the rate because there were too few births to compute a statistically reliable rate. When the number of events in the numerator is greater than 20 but less than 100 , the confidence interval for a rate can be estimated using the two formulas that follow and the values in Table IV.

$$
\begin{aligned}
& \text { Lower limit }=R \times L \\
& \text { Upper limit }=R \times U
\end{aligned}
$$

where:
$R=$ the birth rate
$L=$ the value in Table IV that corresponds to the number $B$ in the numerator of the rate
$U=$ the value in Table IV that corresponds to the number $B$ in the numerator of the rate

## Example

Suppose that the first birth rate for American Indian women 40-44 years of age was 0.54 per 1,000 , based on 47 births in the numerator. Using Table IV:

Lower limit $=0.54 \times 0.73476=.40$
Upper limit $=0.54 \times 1.32979=.72$
This means that the chances are 95 out of 100 that the actual first birth rate for American Indian women 40-44 year of age lies between .40 and .72.

## 95-percent confidence IImits for rates when the numerator is 100 or more

In this case, use the following formula for the birth rate $R$ based on the number of births $B$ :

Lower limit $=R-[1.96 \times(R / \sqrt{B})]$
Upper limit $=R+[1.96 \times(R / \sqrt{B})]$
where:
$R=$ the birth rate
$B=$ the number of births

## Example

Suppose that the first birth rate for white women 40-44 years of age was 1.55 per 1,000 , based on 14,108 births in the numerator. Therefore, the 95 -percent confidence interval would be:

$$
\begin{aligned}
\text { Lower limit } & =1.55-[1.96 \times(1.55 / \sqrt{14,108})] \\
& =1.55-.026 \\
& =1.52
\end{aligned}
$$

Table IV. Values of $L$ and $U$ for calculating 95 percent confidence limits for numbers of events and rates when the number of events is less than 100

$$
\begin{aligned}
\text { Upper limit } & =1.55+[1.96 \times(1.55 / \sqrt{14,108})] \\
& =1.55+.026 \\
& =1.58
\end{aligned}
$$

This means that the chances are 95 out of 100 that the actual first birth rate for white women $40-44$ years of age lies between 1.52 and 1.58 .

## Computing 95-percent confidence intervals for percents

In many instances we need to compute the confidence intervals for percents. Percents derive from a binomial distribution. As with birth rates, an asterisk will be shown for any percent that is based on fewer than 20 births in the numerator. We easily compute a 95 -percent confidence interval for a percent when the following conditions are met:
$B \times p>=5$ and $B \times q>=5$
where:
$B=$ number of births in the denominator $p=$ percent divided by 100

```
q=1-p
```

For natality data, these conditions will be met except for very rare events in small subgroups. If the conditions are not met, the variation in the percent will be so large as to render the confidence intervals meaningless. When these conditions are met the 95 -percent confidence interval can be computed using the nomal approximation of the binomial. The 95 -percent confidence intervals are computed by the following formulas:

$$
\begin{aligned}
& \text { Lower limit }=p-\left(1.96 \sqrt{\frac{p q}{B}}\right) \\
& \text { Upper limit }=p+\left(1.96 \sqrt{\frac{p q}{B}}\right)
\end{aligned}
$$

where:
$B=$ number of births in the denominator
$p=$ percent divided by 100
$q=1-p$

## Example

Suppose that the percent of births to Hispanic women in Alabama that were to unmarried women was 23.0 percent. This was based on 310 bitths in the numerator and 1,345 births in the denominator. First we test to make sure we can use the nomal approximation of the binomial:

$$
\begin{aligned}
& 1,345 \times .230=309 \\
& 1,345 \times(1-.230)=1,345 \times .770=1,036
\end{aligned}
$$

Both 309 and 1,036 are greater than 5 so we can proceed. The 95 -percent confidence interval would be:

$$
\begin{aligned}
\text { Lower limit } & =.23-\left[1.96 \sqrt{\left.\frac{.23(.77)}{1,345}\right]}\right. \\
& =.23-.022 \\
& =.208, \text { or } 20.8 \text { percent }
\end{aligned}
$$

Upper limit $=.23+\left[1.96 \sqrt{\frac{.23(.77)}{1,345}}\right]$

$$
\begin{aligned}
& =.23+.022 \\
& =.252 \text {, or } 25.2 \text { percent }
\end{aligned}
$$

This means that the chances are 95 out of 100 that the actual percent of births in Alabama to Hispanic women that are to unmaried women lies between 20.8 and 25.2 percent.

## Significance testing

## One of the rates is based on fewer than 100 cases

To compare two rates, when one or both of those rates are based on less than 100 cases, you first compute the confidence intervals for both rates. Then you check to see if those intervals overlap. If they do overlap, the difference is not statistically significant at the 95 -percent level. If they do not overlap, the difference is indeed "statistically significant."

## Example

Is the first birth rate for American Indian women 40-44 years of age $(.54$ per 1,000$)$ significantly lower than the comparable rate for white women (1.55)? The rate for American Indian women is based on 47 events whereas the rate for white women is based on 14,108 events. The rate for American Indian women is based on less than 100 events; therefore, the first step is to compute the confidence intervals for both rates.

| Lower Limit | Upper Limit |
| :---: | :---: |
| 0.40 | 0.72 |
| 1.52 | 1.58 |

These two confidence intervals do not overlap. Therefore, the first birth rate for American Indian women aged 40-44 years is significantly lower (at the 95 -percent confidence level) than the comparable rate for white women.

## Both rates are based on 100 or more events

When both rates are based on 100 or more events, the difference between the two rates is considered statistically significant if it exceeds the statistic in the formula below. This statistic equals 1.96 times the standard error for the difference between two rates.
$1.96 \sqrt{\frac{R_{1}^{2}}{N_{1}}+\frac{R_{2}^{2}}{N_{2}}}$
where:
$R_{1}=$ first rate
$R_{2}=$ second rate
$N_{1}=$ first number of births
$\mathrm{N}_{2}=$ second number of births
If the difference is greater than this statistic, then the difference would occur by chance less than 5 times out of 100 . If the difference is less than this statistic, the difference might occur by chance more than 5 times out of 100 . We say that the difference is not statistically significant at the 95 -percent confidence level.

## Example

Is the first birth rate for black women 40-44 years of age (1.08 per 1,000 ) significantly lower than the comparable rate for white women (1.55)? Both rates are based on more than 100 births ( 1,535 for black women and 14,108 for white women). The difference between the rates is $1.55-1.08=.47$. The statistic is then calculated as follows:

$$
\begin{aligned}
& 1.96 \sqrt{\frac{1.08^{2}}{1,535}+\frac{1.55^{2}}{14,108}} \\
& =1.96 \times \sqrt{[(1.166 / 1,535)+(2.403 / 14,108)]} \\
& =1.96 \times \sqrt{0.00076+0.00017} \\
& =1.96 \times \sqrt{0.00093} \\
& =1.96 \times .03 \\
& =.06
\end{aligned}
$$

The difference between the rates (.47) is greater than this statistic (.06). Therefore, the difference is statistically significant at the 95 -percent confidence level.

## Testing differences between two percents

When testing the difference between two percents, both percents must meet the following conditions:

$$
B \times p>=5 \text { and } B \times q>=5
$$

where:
$B=$ number of births in the denominator

$$
\begin{aligned}
& p=\text { percent divided by } 100 \\
& q=1-p
\end{aligned}
$$

When both percents meet these conditions then the difference between the two percents is considered statistically significant if it exceeds the statistic in the formula below. This statistic equals 1.96 times the standard error for the difference between two percents.
$1.96 \sqrt{p(1-p)\left(\frac{1}{B_{1}}+\frac{1}{B_{2}}\right)}$
where:
$B_{1}=$ number of births in the denominator for the first percent
$B_{2}=$ number of births in the denominator for the second percent

$$
p=\frac{B_{1} p_{1}+B_{2} p_{2}}{B_{1}+B_{2}}
$$

$p_{1}=$ first percent divided by 100
$p_{2}=$ second percent divided by 100

## Example

Is the percent of births to Hispanic women that were to unmarried women higher in Alaska ( 28.8 percent) than in Alabama (23.0). The number in the denominator was 1,345 in Alabama and 593 in Alaska. The necessary conditions are met for both percents (calculations not shown). The difference between the two percents is $.288-.230=.058$. The statistic is then calculated as follows:

$$
\begin{aligned}
1.96 \sqrt{.248(.752)(.00243)} & =1.96 \times \sqrt{.00045} \\
& =1.96 \times .021 \\
& =.042
\end{aligned}
$$

The difference between the percents (.058) is greater than this statistic (.042). Therefore, the difference is statistically significant at the 95 -percent confidence level.

## Definitions of medical terms

The 1989 revision of the U.S. Standard Certificate of Live Birth includes several maternal and infant health items in checkbox format, including obstetric procedures, medical risk factors, complications of labor and/or delivery, abnormal conditions of the newbom, and congenital anomalies of the child (figure I). The definitions which follow are adapted and abbreviated from a set of definitions compiled by a committee of Federal and State health statistics olficials for the National Association of Public Health Statistics and Information Systems, formerly known as the Association for Vital Records and Health Statistics (76).

## Medical risk factors for this pregnancy

Anemia-Hemoglobin level of less than $10.0 \mathrm{~g} / \mathrm{dL}$ during pregnancy or a hematocrit of less than 30 percent during pregnancy. Cardiac disease-Disease of the heart.
srute or chronic lung disease-Disease of the lungs during ERIC ${ }^{\text {rey }}$

Diabetes-Metabolic disorder characterized by excessive discharge of urine and persistent thirst; includes juvenile onset, adult onset, and gestational diabetes during pregnancy.

Genital herpes-Infection of the skin of the genital area by herpes simplex virus.

Hydramnios/oligohydramnios-Any noticeable excess (hydramnios) or lack (oligohydramnios) of amniotic fluid.

Hemoglobinopathy-A blood disorder caused by alteration in the genetically determined molecular structure of hemoglobin (example: sickle cell anemia).

Hypertension, chronio-Blood pressure persistently greater than 140/90, diagnosed prior to onset of pregnancy or before the 20th week of gestation.

Hypertension, pregnancy-associated-An increase in blood pressure of at least 30 mm Hg systolic or 15 mm Hg diastolic on two measurements taken 6 hours apart after the 20th week of gestation.

Eclampsia-The occurrence of convulsions and/or coma unrelated to other cerebral conditions in women with signs and symptoms of pre-eclampsia.

Incompetent cervix-Characterized by painless dilation of the cervix in the second trimester or early in the third trimester of pregnancy, with premature expulsion of membranes through the cervix and ballooning of the membranes into the vagina, followed by rupture of the membranes and subsequent expulsion of the fetus.

Previous infant $4,000+$ grams-The birth weight of a previous live-bom child was over $4,000+$ grams ( 8 pounds 14 ounces).

Previous preterm or small-for-gestational-age infant-Previous birth of an infant prior to term (before 37 completed weeks of gestation) or of an infant weighing less than the tenth percentile for gestational age using a standard weight for age chart.

Renal disease-Kidney disease.
Rh sensitization-The process or state of becoming sensitized to the Rh factor as when an Rh -negative woman is pregnant with an Rh-positive fetus.

Uterine bleeding-Any clinically significant bleeding during. the pregnancy taking into consideration the stage of pregnancy; any second or third trimester bleeding of the uterus prior to the onset of labor.

## Obstetrlc procedures

Amniocentesis-Surgical transabdominal perforation of the uterus to obtain amniotic fluid to be used in the detection of genetic disorders, fetal abnormalities, and fetal lung maturity.

Electronic fetal monitoring-Monitoring with extemal devices applied to the matemal abdomen or with intemal devices with an electrode attached to the fetal scalp and a catheter through the cervix into the uterus, to detect and record fetal heart tones and uterine contractions.

Induction of labor-The initiation of uterine contractions before the spontaneous onset of labor by medical and/or surgical means for the purpose of delivery.

Stimulation of labor-Augmentation of previously established labor by use of oxytocin.

Tocolysis-Use of medications to inhibit preterm uterine contractions to extend the length of pregnancy and, therefore, avoid a preterm birth.

Ultrasound-Visualization of the fetus and the placenta by means of sound waves.

Figure I．Selected maternal and infant health items from the 1989 revision of the U．S．Standard Certificate of Live Birth

## Compllcations of labor and／or dellvery

Febrile－A fever greater than 100 degrees F．or 38 C．occurring during labor and／or delivery．

Meconium，moderate／heav－Meconium consists of undigested debris from swallowed amniotic fluid，various products of secretion， excretion and shedding by the gastrointestinal tract；moderate to heavy amounts of meconium in the amniotic fluid noted during labor and／or delivery．

Premature rupture of membranes（more than 12 hours）－Rupture of the membranes at any time during pregnancy and more than 12 hours before the onset of labor．

Abruptio placenta－Premature separation of a normally implanted placenta from the uterus．

Placenta previa－Implantation of the placenta over or near the intemal opening of the cervix．

Other excessive bleeding－The loss of a significant amount of blood from conditions other than abruptio placenta or placenta previa．

Seizures during labor－Maternal seizures occurring during labor from any cause．

Precipitous labor（less than 3 hours）－Extremely rapid labor and delivery lasting less than 3 hours．

Prolonged labor（more than 20 hours）－Abnormally slow progress of labor lasting more than 20 hours．

Dysfunctional labor－Failure to progress in a normal pattem of

Breech／malpresentation－At birth，the presentation of the fetal buttocks rather than the head，or other malpresentation．

Cephalopelvic disproportion－The relationship of the size，pre－ sentation，and position of the fetal head to the matemal pelvis which prevents dilation of the cervix and／or descent of the fetal head．

Cord prolapse－Premature expulsion of the umbilical cord in labor before the fetus is delivered．

Anesthetic complications－Any complication during labor and／or delivery brought on by an anesthetic agent or agents．

Fetal distress－Signs indicating fetal hypoxia（deficiency in amount of oxygen reaching fetal tissues）．

## Abnormal condiltions of the newborn

Anemia－Hemoglobin level of less than $13.0 \mathrm{~g} / \mathrm{dL}$ or a hematocrit of less than 39 percent．

Bith injury－Impaiment of the infant＇s body function or structure due to adverse influences which occurred at birth．

Fetal alcohol syndrome－A syndrome of altered prenatal growth and development occuring in infants born of women who consumed excessive amounts of alcohol during pregnancy．

Hyaline membrane disease／RDS－A disorder primarily of prema－ turity，manifested clinically by respiratory distress and pathologically by pulmonary hyaline membranes and incomplete expansion of the lungs at birth．

Meconium aspiration syndrome-Aspiration of meconium by the fetus or newbom, affecting the lower respiratory system.

Assisted ventilation (less than 30 minutes)-A mechanical method of assisting respiration for newboms with respiratory failure.

Assisted ventilation ( 30 minutes or more)-Newborn placed on assisted ventilation for 30 minutes or longer.

Seizures-A seizure of any etiology.

## Congenital anomalies of chlld

Anencephalus-Absence of the cerebral hemispheres.
Spina bifida/meningocele-Developmental anomaly characterized by defective closure of the bony encasement of the spinal cord, through which the cord and meninges may or may not protrude.

Hydrocephalus-Excessive accumulation of cerebrospinal fluid within the ventricles of the brain with consequent enlargement of the cranium.

Microcephalus-A significantly small head.
Other central nervous system anomalies-Other specified anomalies of the brain, spinal cord, and nervous system.

Heart malformations-Congenital anomalies of the heart.
Other circulatory/respiratory anomalies-Other specified anomalies of the circulatory and respiratory systems.

Rectal atresia/stenosis-Congenital absence, closure, or narrowing of the rectum.

Tracheo-esophageal fistula/Esophageal atresia-An abnormal passage between the trachea and the esophagus; esophageal atresia is the congenital absence or closure of the esophagus.

Omphalocele/gastroschisis-An omphalocele is a protrusion of variable amounts of abdominal viscera from a midline defect at the base of the umbilicus. In gastroschisis, the abdominal viscera protrude through an abdominal wall defect, usually on the right side of the umbilical cord insertion.

Other gastrointestinal anomalies-Other specified congenital anomalies of the gastrointestinal system.

Malformed genitalia-Congenital anomalies of the reproductive organs.

Renal agenesis-One or both kidneys are completely absent.
Other urogenital anomalies-Other specified congenital anomalies of the organs concerned in the production and excretion of urine, together with organs of reproduction.

Cleft lip/palate-Cleft lip is a fissure or elongated opening of the lip; cleft palate is a fissure in the roof of the mouth. These are failures of embryonic development.

Polydactyly/syndactyly/adactyly—Polydactyly is the presence of more than five digits on either hands and/or feet; syndactyly is having fused or webbed fingers and/or toes; adactyly is the absence of fingers and/or toes.

Club foot-Deformities of the foot, which is twisted out of shape or position.

Diaphragmatic hemia-Hemiation of the abdominal contents through the diaphragm into the thoracic cavity usually resulting in respiratory distress.

Other musculoskeletal/integumental anomalies-Other specified congenital anomalies of the muscles, skeleton, or skin.

Down's syndrome-The most common chromosomal defect with most cases resulting from an extra chromosome (trisomy 21).

Sther chromosomal anomalies-All other chromosomal

## Related reports

Many of the topics discussed in this report are covered in more analytic detail in other reports published by NCHS. Topics of reports published in the past 5 years include Hispanic origin births (4); twin and triplet biths $(62,63)$; teenage birth rates by State $(6,21)$; bith rates by educational attainment of the mother (77); cesarean deliveries, attendant at bith, place of delivery, and obstetric procedures ( 53,78 ); biths to unmaried mothers (23); trends in pregnancies and pregnancy rates (7), and trends in smoking (32).

This report presents summary tabulations from the final natality statistics for 1998. The National Center for Health Statistics will respond to requests for unpublished data whenever possible.

    1 Includes births to Aleuts and Eskimos.
    Excludes births to Aleuts and Eskimos.
    Excludes data for California and South Dakota, which did not report alcohol use on the blith certificate.
    Excludes data for Callifornla, which did not report weight galn on the birth certificate. Median weight shown in pounds.
    Bom prior to 37 completed weeks of gestation.
    Birthweight of less than 1,500 grams ( 3 lb 4 oz )
    Birthweight of less than 2,500 grams ( 5 lb 8 oz ).
    Equivalent to 8 bl 14 oz .
    Excludes data for California and Texas, which did not report 5-minute Apgar score on the birth certlicate

[^21]:    1 Includes origin not stated.
    includes races other than white and black.
    Excludes data for Calitornia, Indiana, Now York State (but includes Now York City), and South Dakota, which did not report tobacco use on the birth certificate.
    Excludes data for California and South Dakota, which did not report alcohol use on the bith certificate.
    Excludas data for Californla, which did not report weight gain on the bith certificate. Median weight gain shown in pounds.
    Eorn prior to 37 completed weeks of gestation.
    Birthweight of less than 1,500 grams ( 3 lb 4 Oz ).
    Birthweight of less than 2,500 grams (5 lb 8 oz).
    Equlvalent to 8 bl 14 oz .
    Excludes data for Calitornia and Texas, which did not report 5-minute Apgar score on the bith certificate.

[^22]:    1 Total number of births to residents of areas reporting specified medical risk factor.
    2 Includes races other than white and black.
    3 Texas does not report this risk factor.
    4 Kansas does not report this risk factor.

[^23]:    1 Includes births to Aleuts and Eskimos.
    2 Texas does not repont this risk factor.
    3 Texas does not report this complication.

[^24]:    2 Includes origin not stated,
    3 Texas does not report this risk factor.
    4 Texas does not report this risk facior.

[^25]:    - Figure does not meet standards of reliability or precislon; based on fewer than 20 bliths in the numerator or denominator.

[^26]:    *Figure does not meet standards of rellability or precision; based on fewer than 20 blths in the numerator or denominator
    1 Includes races other than white and black and origin not stated.
    2 includes all persons of Hispanic origin of any race.

[^27]:    *Flgure does not meet standards of rellability or precision; based on fewer then 20 births in the numerator or denominator.
    1 includes races other than white and black and origin not stated.
    2 includes all persons of Hispanic origin of any race.

[^28]:    See footnotes at end of table.

[^29]:    * Figure does not meet standards of reliability or precision; based on fewer than $\mathbf{2 0}$ births in the numerator or denominator.
    - 1 Data not available.

    1 Care beginning In 3rd trimester.
    2 Includes races other than white and black and origin not stated.
    3 Includes all persons of Hispanic origin of any race.
    4 Excludes data for the territorles.

[^30]:    i Category not applicable.
    1 Includes races other than white and black and origin not stated.
    2 Includes all persons of Hispanic orlgin of any race.

[^31]:    - Figure does not meet standards of reliability or precision; based on fewer than 20 births in the numerator or denominator.

    1 Total number of biths to residents of areas reporting specified compllcation.
    2 Includes races other than white and black.
    3 Texas does not report this complication.
     each race group according to the mother's reported race; see Technical notes

[^32]:    - Quantity zero.

    1 Includes races other than while and black and origin not stated.
    2 Includes births occurring en route to or on arival at hosptal.
    3 Includes all persons of Hispanic origin of any race.

[^33]:    Percent of all ive births by cesarean delvery.
    Number of primary cesareans per 100 tive births to women who have not hed a previous cesarean.
    Number of vaginal births after previous cesarean delvery per 100 live births to women with a previous cesarean delvery.
    Includes races other than white and black and origin not stated.
    Excludes data for Oklahoma, which did not report method of delivery on the birth certificate.
    Excludes data for Loulsiana, Maryland, Nebraska, Novada, and Oklahoma, which did not report method of delivery on the birth certificate.
    Includes all persons of Hispanic origin of any race.
    Excludes data for New Hampshtre which did not report Hispanic origin.
    Excludes data for New Hampshire and Okiahoma which did not report Hispanic origin
    10 Excludes data for Loulslana, New Hampshire, and Oklahoma, which did not report Hispanic origin.

[^34]:    1 Percent of all live biths by cesarean delivery.
    ${ }_{3}$ Number of primary cesareans per 100 live births to women who have not had a previous cesarean.
    4 Number of vaginal births after prevlous cesarean delivery per 100 live bliths to women with a previous cesarean delivery.
    4 Includes races other than whilte and black and origin not stated.
    includes all persons of Hispanic origin of any race.

[^35]:    1 Percent of all live births by cesarean delivery.
    2 Number of primary cesareans per 100 live births to women who have not had a previous cesarean.
    Number of primary cesareans per 100 live biths to women who have nod had a previous cesarean.
    Texas does not report this risk factor.
    5 Kansas does not report this risk factor.
    Texas does not report thls complication.

[^36]:    See footnotes at end of table.

[^37]:    - Quantity zero.
    0.0 Quantity more than zero but less than 0.05 .

    Equivalents of the gram weights in pounds and ounces are shown In the Technical notes.
    2 Expressed in completed weeks.
    3 Includes races other than white and black and origin not stated.
    4 Birthweight of less than 1,500 grams ( 3 lb 4 oz ).
    5 Birthweight of less than 2,500 grams ( 5 lb 8 oz ).
    6 Includes all persons of Hispanic origin of any race.

[^38]:    -- Data not available.
    Births of less than 32 completed weeks of gestation.
    2 Births of less than 37 completed weeks of gestation.
    3 Includes races other than white and black and origin not stated.
    4 Includes all persons of Hispanic origin of any race.
    Less than 1,500 grams ( 3 lb .4 oz .).
    Less than 2,500 grams ( 5 lb .8 oz .)
    Data by Hispanic origin exclude New Hampshire, which did not report Hispanic Origin.
    Data by Hispanic origin exclude New Hampshire and Oklahoma, which did not report Hispanic origin.
    Data by Hispanic origin exclude New Hampshire, Oklahoma, and Louisiana, which did not report Hispanle origin.

[^39]:    All races ${ }^{3}$

[^40]:    Figure does not meet standards of reliablity or precision; based on fewer than 20 births in the numerator or denominator.
    -- Data not available.
    Includes races other than white and black and origin not stated.
    3 Includes all persons of Hispanic origin of any race.
    3 Excludes data for the territories.

[^41]:    * Figure does not meet standards of reliability or precision; based on fewer than 20 births in the numerator or denominator.
    - Quantity zero.
    .-. Data not available.
    1 Data not available.
    2 Includes all persons of Hispanic origin of any race.
    Excludes data for the territories.

[^42]:    - Figure does not meet standards of reliability or precision; based on fewer than $\mathbf{2 0}$ births in the numerator or denominator.
    0.0 Quantity more than zero but less than 0.05 .

    1 Total number of biths to residents of areas reporting specified condition.
    2 Includes races other than white and black.
    3 Nebraska and Texas do not report this condition.
    4 Wisconsin does not report this condifion.
    5 New York City does not report this condition.
    NOTE: Race and Hispanic origin are reported separately on birth certlicates. In this table all women (Including Hispanic women) are classifled only according to their race; see Technical notes.

[^43]:    *Figure does not meet standards of reliability or precision; based on fewer than 20 births in the numerator or denominator.
    1 Total number of births.
    2 Includes races other than white and black.
     women) are classified only according to their race; see Technical notes.

[^44]:    - Quantity zero.
    *Figure does not meet standards of reliability or precision; based on fewer than 20 births in the numerator or denominator.
    1 Includes races other than white and black and origin not stated.
    2 Includes races oll persons of Hispanic origin of any race.
    Births in greater than twin detiveries.

[^45]:    0.0 Quamity more than zero but less than 0.05 .

[^46]:    Less than 500 grams $=1 \mathrm{lb} 1 \mathrm{oz}$ or less
    $500-999$ grams $=1 \mathrm{lb} 2 \mathrm{oz}-2 \mathrm{lb} 3 \mathrm{oz}$
    $1,000-1,499$ grams $=2 \mathrm{lb} 402-3 \mathrm{lb} 4 \mathrm{oz}$
