We study the decays $B^0 \rightarrow J/\psi \pi^+ \pi^-$ and $B^+ \rightarrow J/\psi \pi^+ \pi^0$, including intermediate resonances, using a sample of 382×10^6 $B\bar{B}$ pairs recorded by the *BABAR* detector at the PEP-II e^+e^- B factory. We measure the branching fractions $\mathcal{B}(B^0 \rightarrow J/\psi \rho^0) = (2.7 \pm 0.3 \pm 0.2) \times 10^{-5}$ and $\mathcal{B}(B^+ \rightarrow J/\psi \rho^+) = (5.0 \pm 0.7 \pm 0.3) \times 10^{-5}$. We also set the following upper limits at the 90% confidence level: $\mathcal{B}(B^0 \rightarrow J/\psi \pi^+ \pi^- \text{ nonresonant}) < 1.2 \times 10^{-5}$, $\mathcal{B}(B^0 \rightarrow J/\psi f_2) < 4.6 \times 10^{-6}$, and $\mathcal{B}(B^+ \rightarrow J/\psi \pi^+ \pi^0 \text{ nonresonant}) < 7.3 \times 10^{-6}$. We measure the charge asymmetry in charged B decays to $J/\psi \rho$ to be $-0.11 \pm 0.12 \pm 0.08$.

DOI: 10.1103/PhysRevD.76.031101

PACS numbers: 13.25.Hw, 12.15.Hh

The decay $B^0 \rightarrow J/\psi \rho^0$ [1] can in principle be used to measure the CP violation parameter $\sin 2\beta$. However, the measurement is not as straightforward as that of $\sin 2\beta$ in $J/\psi K_S^0$ decays [2,3], because it involves the decay of a pseudoscalar meson to two vector mesons, resulting in both CP -odd and CP -even final states. Furthermore, the decay can proceed through either a color-suppressed tree diagram or a penguin diagram, both shown in Fig. 1, and interference between them could result in direct CP violation [4]. Direct CP violation may also occur in $B^+ \rightarrow J/\psi \rho^+$ decays, where it would manifest itself as a nonzero charge asymmetry:

$$\mathcal{A}_{CP} = \frac{N(B^- \rightarrow J/\psi \rho^-) - N(B^+ \rightarrow J/\psi \rho^+)}{N(B^- \rightarrow J/\psi \rho^-) + N(B^+ \rightarrow J/\psi \rho^+)}. \quad (1)$$

The large intrinsic width of the ρ meson necessitates an analysis of a significant portion of the invariant mass spectrum of the dipion system.

The branching fraction for $B^0 \rightarrow J/\psi \pi^+ \pi^-$ has previously been measured at *BABAR* to be $(4.6 \pm 0.7 \pm 0.6) \times 10^{-5}$ [5], including a $J/\psi \rho^0$ component with a branching fraction of $(1.6 \pm 0.6 \pm 0.4) \times 10^{-5}$. This measurement used a data sample containing approximately 56×10^6 $B\bar{B}$ pairs, which is a subset of the sample used in this analysis. The charged B decay to $J/\psi \rho^+$ has not previously been observed; the CLEO Collaboration set an upper

limit $\mathcal{B}(B^+ \rightarrow J/\psi \rho^+) < 7.7 \times 10^{-4}$ at the 90% confidence level [6].

The data sample used here contains 382×10^6 $B\bar{B}$ pairs collected with the *BABAR* detector at the PEP-II asymmetric-energy e^+e^- storage ring, taken at a center-of-mass (CM) energy equivalent to the mass of the $\Upsilon(4S)$ resonance. An additional data sample, corresponding to an integrated luminosity of 36.8 fb^{-1} , taken at a CM energy 40 MeV below the $\Upsilon(4S)$ resonance, is used to study backgrounds from continuum $q\bar{q}$ production, where $q = u, d, s, c$.

A detailed description of the *BABAR* detector can be found elsewhere [7]. Charged-particle trajectories are measured by a five-layer silicon vertex tracker (SVT) and a 40-layer drift chamber (DCH) operating in a 1.5 T solenoidal magnetic field. A detector of internally reflected Cherenkov light (DIRC) is used for charged hadron identification. Surrounding this is a CsI(Tl) electromagnetic calorimeter (EMC), and finally the instrumented flux return (IFR) of the solenoid, which consists of layers of iron interspersed with resistive plate chambers or limited streamer tubes.

The J/ψ meson is reconstructed in decays to l^+l^- , where l^\pm refers to a charged lepton, e^\pm or μ^\pm . Electrons are selected on the basis of the ratio of EMC shower energy to track momentum, and the energy profile of the EMC shower. For $J/\psi \rightarrow e^+e^-$ an attempt is made to recover energy losses from bremsstrahlung, by looking for showers in the EMC close to those from the electron candidates. This procedure increases the selection efficiency for $J/\psi \rightarrow e^+e^-$ candidates by approximately 30% [8]. The muon selection algorithm uses a neural network, for which the most important input is the number of interaction lengths traversed in the IFR. The lepton pairs are fitted to a common vertex and the invariant mass of the combination is required to be in the range 2.98 (3.06) to 3.14 GeV/c^2 for the e^+e^- ($\mu^+\mu^-$) channels. In order to reduce the background from $B^0 \rightarrow J/\psi K^{*0}$ ($K^{*0} \rightarrow K^+\pi^-$) decays, charged pion candidates are required to satisfy stringent particle identification criteria, based on combined ionization energy loss (dE/dx) in the DCH and SVT, and the Cherenkov angle measured in the DIRC.

All tracks are required to originate close to the interaction point, and to lie in polar angle ranges where particle identification efficiency is well measured. The allowed ranges correspond to the geometric acceptances of the

FIG. 1. Tree and penguin diagrams for the process $B^0 \rightarrow J/\psi \rho^0$.

DIRC for pions, the EMC for electrons, and the IFR for muons.

Neutral pion candidates are formed by combining pairs of isolated showers in the EMC. These are required to spread over a minimum of three crystals, and to have an energy greater than 200 MeV.

To form a B candidate, the reconstructed J/ψ is combined with either a pair of oppositely charged pions, or a charged pion and a π^0 , and a kinematic and geometric fit is used to ensure that all final state particles are consistent with coming from the same decay point. In this fit, we constrain the invariant mass of the l^+l^- and the $\gamma\gamma$ to have the nominal mass of the J/ψ and π^0 respectively [9]. The energy difference, ΔE , between the candidate energy and the single beam energy, E_{beam}^{CM} (both in the CM frame) is expected to be close to zero for signal events, and is therefore required to be in the interval -40 to 40 MeV (-60 to 80 MeV) for B^0 (B^+) candidates, corresponding to approximately $\pm 3\sigma$ of the ΔE resolution. Note that the range is asymmetric for B^+ candidates because the π^0 in the final state gives rise to a tail on the low side of the distribution, due to the EMC response to photons. For events where more than one B candidate passes the selection criteria, the candidate with the smallest value of $|\Delta E|$ is chosen.

The branching fraction for each signal channel is obtained from:

$$\mathcal{B} = \frac{N_{\text{sig}}}{N_{B\bar{B}} \times \epsilon_{\text{sig}} \times \mathcal{B}(J/\psi \rightarrow l^+l^-)}, \quad (2)$$

where N_{sig} and ϵ_{sig} are the observed yield and selection efficiency, respectively, for a specific signal channel, and $N_{B\bar{B}}$ is the number of B meson pairs. We assume that the $\Upsilon(4S)$ decays equally often into neutral and charged B meson pairs. The $J/\psi \rightarrow l^+l^-$ branching fraction is taken to be $(11.87 \pm 0.12)\%$ [9].

We extract the signal yields for the $J/\psi\rho^0$, $J/\psi\pi^+\pi^-$ nonresonant, and $J/\psi f_2$ channels by performing a fit on the sample of reconstructed B^0 candidates. We also perform a similar fit to the sample of charged B candidates in order to obtain the signal yields for the decay channels $B^+ \rightarrow J/\psi\rho^+$ and $B^+ \rightarrow J/\psi\pi^+\pi^0$ nonresonant. The fits are two-dimensional, extended, unbinned maximum likelihood fits to the distributions of m_{ES} and $m_{\pi\pi}$, where $m_{\text{ES}} = \sqrt{(E_{\text{beam}}^{CM})^2 - (p_B^{CM})^2}$ is the beam-energy substituted B mass, and $m_{\pi\pi}$ is the invariant mass of the dipion system. Seven event categories are considered: (i) $J/\psi\rho$ signal, (ii) $J/\psi\pi\pi$ nonresonant signal, (iii) $J/\psi f_2$ signal, (iv) $J/\psi K_S^0$ events, (v) background events that do not contain a J/ψ (non- J/ψ background), (vi) background events containing a J/ψ (inclusive J/ψ background), and (vii) selected background channels that have been studied in more detail (exclusive J/ψ backgrounds). In the fit to neutral B candidates, the decay channels that comprise category (vii) are

$J/\psi K^{*0}$, $J/\psi K^{*+}$, $J/\psi K_1(1270)$, $J/\psi K^+$, $J/\psi\rho^+$ [10], and $J/\psi\pi^+$. For the fit to charged B candidates, the exclusive J/ψ background channels are $J/\psi K^{*0}$, $J/\psi K^{*+}$, $J/\psi K_1(1270)$, $J/\psi K^+$, $J/\psi K_S^0$, and $J/\psi K_L^0$. In both cases, these decay channels are not included in category (vi). Of course, categories (iii) and (iv) are only present in the fit to neutral B candidates.

A probability density function (PDF) is constructed for each category, and the sum of these PDFs is used to fit the data. The likelihood function for the total sample is the product of the PDF values for each candidate, multiplied by a Poisson factor:

$$\mathcal{L} = \frac{1}{N!} e^{-N'} (N')^N \prod_{i=1}^N \mathcal{P}_i, \quad (3)$$

where N and N' are the numbers of observed and expected events, respectively, and \mathcal{P}_i is the value of the total PDF for event i . For all event categories except for the exclusive J/ψ background, \mathcal{P}_i is a product of one-dimensional PDFs in m_{ES} and $m_{\pi\pi}$.

Figure 2 shows the m_{ES} and $m_{\pi\pi}$ distributions for the data, and the projections of the PDFs for each category. The functional forms of these PDFs are as follows. For the $J/\psi\rho^0$, $J/\psi\pi^+\pi^-$, $J/\psi f_2$, and $J/\psi K_S^0$ components, the m_{ES} distributions are parametrized by Gaussian functions, all with the same values for the mean and width, which are allowed to float in the fit. In the fit to charged B candidates, a Crystal Ball function [11] is used instead for the m_{ES} distributions of the $J/\psi\rho^+$ and $J/\psi\pi^+\pi^0$ signal components, as the presence of a π^0 in the final state gives rise to a tail on the low mass side of the peak.

The $J/\psi\rho$ signal component is modeled by a relativistic P -wave Breit-Wigner function [13] in $m_{\pi\pi}$:

$$F_\rho(m_{\pi\pi}) = \frac{m_{\pi\pi}\Gamma(m_{\pi\pi})P^{2L_{\text{eff}}+1}}{(m_\rho^2 - m_{\pi\pi}^2)^2 + m_\rho^2\Gamma(m_{\pi\pi})^2}, \quad (4)$$

where $\Gamma(m_{\pi\pi}) = \Gamma_0 \left(\frac{q}{q_0}\right)^3 \left(\frac{m_\rho}{m_{\pi\pi}}\right) \frac{1+R^2q_0^2}{1+R^2q^2}$. The parameter $q(m_{\pi\pi})$ is the pion momentum in the dipion rest frame, with $q_0 = q(m_\rho)$; P is the J/ψ momentum in the B rest frame; L_{eff} is the orbital angular momentum between the J/ψ and the ρ , which can be 0, 1 or 2; R is the radius of the Blatt-Weisskopf barrier factor [14,15], which is taken to be (0.5 ± 0.5) fm; and m_ρ is the ρ meson mass.

The $m_{\pi\pi}$ distribution for the $J/\psi\pi\pi$ nonresonant signal is $F_{\pi\pi} = q(m_{\pi\pi})P^3$, the product of a three-body phase space factor $q(m_{\pi\pi})P$ and a factor P^2 motivated by angular momentum conservation.

For the $J/\psi f_2$ component, the $m_{\pi\pi}$ distribution is described by a relativistic D -wave Breit-Wigner, similar to Eq. (4), but with an extra factor $(q/q_0)^2$ in the expression for $\Gamma(m_{\pi\pi})$.

The decays to $J/\psi K_S^0$ are not considered signal for this analysis. Most of them are removed by the requirement that all tracks are consistent with coming from the same vertex.

FIG. 2 (color online). Distributions of (a) m_{ES} and (b) $m_{\pi\pi}$ for $B^0 \rightarrow J/\psi\pi^+\pi^-$ candidates. The solid line represents the total PDF, while the other lines represent (cumulatively, from the bottom of the plot) non- J/ψ background, inclusive J/ψ background, exclusive J/ψ background, $J/\psi\pi^+\pi^-$ nonresonant signal, and $J/\psi f_2$ signal. The points with error bars represent the data and statistical errors. The sharp spike in (b) corresponds to $J/\psi K_S^0$ events, while the broader peak is due to $J/\psi\rho^0$ events.

The $m_{\pi\pi}$ distribution of the remaining $J/\psi K_S^0$ events is modeled by a narrow Gaussian function.

Non- J/ψ background events are modeled by an ARGUS function [16] in m_{ES} . The $m_{\pi\pi}$ PDF is the sum of two Weibull functions [18], and a Breit-Wigner to describe the ρ component of the continuum background. The parameters of this PDF are fixed to values obtained from fits to the J/ψ mass sidebands of the data.

The m_{ES} distribution of the inclusive J/ψ background is an ARGUS function plus a Gaussian at the B mass. The width of this Gaussian is somewhat wider than that used for signal components, as it represents B candidates that are not correctly reconstructed. The $m_{\pi\pi}$ PDF is a 4th-order polynomial. The PDF parameters for this component are fixed to values obtained by fits to a large sample of $B \rightarrow J/\psi(\rightarrow l^+l^-)X$ Monte Carlo (MC) simulated events, with

signal events and exclusive J/ψ background channels removed.

Each of the exclusive J/ψ background channels is modeled by a two-dimensional PDF derived from the distribution of MC events for that decay channel. The normalizations of these PDFs are determined by taking into account the selection efficiency on MC simulation, and the world average branching fractions [9].

For the branching fraction fit to neutral B candidates there are 12 free parameters: the yields of the $J/\psi\rho$, $J/\psi\pi\pi$, $J/\psi f_2$, $J/\psi K_S^0$, and inclusive J/ψ background components; the mean and width of the Gaussian used for the signal distribution in m_{ES} ; the parameters m_ρ , Γ_0 , and L_{eff} in the ρ line shape; and the mean and width of the $m_{\pi\pi}$ distribution for the $J/\psi K_S^0$ component. All other parameters are fixed, including those describing the line shape of the $f_2(1270)$, the normalizations and shapes of the exclusive J/ψ background PDFs, and the shapes of the inclusive J/ψ and non- J/ψ background PDFs. We also fix the ratio of non- J/ψ to J/ψ (inclusive plus exclusive) background yields to a value obtained from fitting to data in the region $m_{ES} < 5.26$ (i.e. lower in mass than the signal region), and extrapolated to the fit region using distributions from MC simulation.

The configuration for the charged B branching fraction fit, shown in Fig. 3, is very similar. Here, there are eight free parameters, since there are no $J/\psi K_S^0$ or $J/\psi f_2$ components.

We find from MC simulation studies that correlations between m_{ES} and $m_{\pi\pi}$ give rise to small biases in the numbers of $J/\psi\rho^+$ and $J/\psi\pi^+\pi^0$ nonresonant signal candidates found in the charged B fit. The sizes of these biases are evaluated by examining the distribution of residuals ($N_{\text{obs}} - N_{\text{input}}$) for a large number of MC experiments, and are listed in Table I. The yields obtained from the branching fraction fit are therefore corrected by subtracting these quantities from the fitted yields.

The signal yields and statistical errors obtained from the branching fraction fits are listed in Table I. We also list the statistical significances of the observed signals, $\sqrt{-2 \ln(\mathcal{L}_{\text{Null}}/\mathcal{L}_{\text{max}})}$, where \mathcal{L}_{max} is the likelihood from the fit, and $\mathcal{L}_{\text{Null}}$ is the value of the likelihood function when the fit is performed with the signal yield constrained to zero events. For decay channels where no significant signal is observed, we quote an upper limit at the 90% confidence level, based on integrating the likelihood function over the physically allowed region.

We obtain signal efficiencies using samples of MC signal events. Particle identification efficiency is corrected using data control samples of electrons, muons, and pions. The sizes of these corrections vary with momentum and polar angle, and average corrections are about 1.5% for electrons, 5.9% for muons, and 1.8% for pions. With these corrections applied, about 85% (50%) of electron (muon) pairs, and about 85% of pions, satisfy their respective

TABLE I. Signal yields, detection efficiencies, and branching fractions for the signal decay channels. The fit bias, product of secondary branching fractions ($\mathcal{B}(J/\psi \rightarrow l^+l^-)$ and $\mathcal{B}(\pi^0 \rightarrow \gamma\gamma)$), and significances of the signals (using statistical uncertainties only) are also listed. The corrected yields are obtained by subtracting the fit bias from the fitted yields.

Mode	Fit bias (events)	Corrected yield (events)	ϵ (%)	$\prod \mathcal{B}_i$ (%)	Signif. (σ)	$\mathcal{B}(\times 10^{-5})$
$J/\psi\rho^0$	0	$251.1 \pm 27.5 \pm 11.2$	$20.6 \pm 0.1 \pm 0.8$	11.87 ± 0.12	13.0	$2.7 \pm 0.3 \pm 0.2$
$J/\psi\pi^+\pi^-$	0	$64.5 \pm 35.5 \pm 7.7$	$20.3 \pm 0.1 \pm 0.8$	11.87 ± 0.12	2.0	<1.2 (90% C.L.)
$J/\psi f_2$	0	$24.4 \pm 13.8 \pm 1.8$	$20.3 \pm 0.1 \pm 0.8$	11.87 ± 0.12	2.0	<0.46 (90% C.L.)
$J/\psi\rho^+$	-6.8 ± 1.1	$218.5 \pm 28.8 \pm 9.5$	$9.7 \pm 0.1 \pm 0.4$	11.73 ± 0.12	11.6	$5.0 \pm 0.7 \pm 0.3$
$J/\psi\pi^+\pi^0$	$+8.2 \pm 0.9$	$-12.7 \pm 27.1 \pm 4.7$	$11.9 \pm 0.1 \pm 0.5$	11.73 ± 0.12	0	<0.73 (90% C.L.)

particle identification requirements. A small, energy-dependent correction (typically about -2% relative) is also applied to decay modes containing a π^0 , to account for known differences in photon detection efficiency between data and MC simulation. The corrected signal efficiencies are listed in Table I.

Systematic errors on the branching fraction measurements arise from uncertainties on the signal efficiency, on the fitted yield, on the number of $B^0\bar{B}^0$ or B^+B^- events

in the sample, and on the $J/\psi \rightarrow l^+l^-$ branching fraction. The number of $B\bar{B}$ pairs is known to 1.1% accuracy, and an additional 1.6% uncertainty is assigned corresponding to the assumption that the $Y(4S)$ decays 50% of the time into $B^0\bar{B}^0$ and 50% of the time into B^+B^- [9]. The fractional uncertainty on $\mathcal{B}(J/\psi \rightarrow l^+l^-)$ is 1.0% [9].

The systematic uncertainties on the efficiency are largely due to imperfect simulation of the detector performance. These effects are studied using various data control samples. The largest sources of uncertainty are pion identification efficiency, which gives a 2.0% (3.4%) relative error for charged (neutral) B decay channels, and π^0 efficiency (3% for charged B decays). Tracking efficiency (1.5%) and lepton identification efficiency (1.0%) also contribute to the uncertainty on the efficiency. The polarization of the ρ in $B \rightarrow J/\psi\rho$ decays is unknown. We use an MC sample in which the ρ mesons are unpolarized to obtain the central value of the signal efficiency. We also evaluate the efficiency using MC data samples with different ρ polarizations, and observe a relative variation of 2%, which is assigned as a systematic uncertainty on the branching fraction measurement.

We evaluate the impact of the fit procedure by observing the changes in the yields when varying the PDF parameters that were fixed in the fit within their uncertainties. The resulting differences are added quadratically for sets of parameters that are relatively uncorrelated, and added linearly for highly correlated sets of parameters. We also repeat the fit using alternative functional forms for some PDFs, namely, the shape of the inclusive J/ψ background in $m_{\pi\pi}$, and the ρ line shape, and include the resulting differences in the yield in the systematic uncertainty. In addition, for the $J/\psi\rho^+$ and $J/\psi\pi^+\pi^0$ channels, systematic uncertainties equal to half of the bias corrections listed in Table I are assigned. The total systematic uncertainties on the yield vary from 1.8 events for the $J/\psi f_2$ channel, to 11.2 events for the $J/\psi\rho^0$ channel.

In order to assess the charge asymmetry \mathcal{A}^ρ , we perform a second fit to the charged B candidate sample. In this fit, all the shape parameters for the signal and background components are fixed to values obtained from the branching fraction fit. This reduces the number of free parameters and improves the reliability of the fit. We include terms for the asymmetries in signal and background components as follows:

FIG. 3 (color online). Distributions of (a) m_{ES} and (b) $m_{\pi\pi}$ for $B^+ \rightarrow J/\psi\pi^+\pi^0$ candidates. The solid line represents the total PDF, while the other lines represent the different background components. The points with error bars represent the data.

$$\begin{aligned}
\mathcal{P}_i = & N^\rho \times \frac{1}{2}(1 - Q_i \mathcal{A}^\rho) \mathcal{P}_i^\rho \\
& + N^{NR} \times \frac{1}{2}(1 - Q_i \mathcal{A}^{NR}) \mathcal{P}_i^{NR} \\
& + \sum_j N_j^{bkg} \times \frac{1}{2}(1 - Q_i \mathcal{A}_j^{bkg}) \mathcal{P}_{j,i}^{bkg}, \quad (5)
\end{aligned}$$

where N^ρ , N^{NR} , and N_j^{bkg} are the yields for the $J/\psi\rho^+$ signal, the $J/\psi\pi^+\pi^0$ nonresonant signal, and the different background components j , respectively; Q_i is the charge of the B candidate in event i ; and \mathcal{A}^ρ , \mathcal{A}^{NR} , and \mathcal{A}_j^{bkg} are the corresponding charge asymmetries. The asymmetry parameters for the exclusive J/ψ background channels are fixed to world average values [9]. The asymmetries for the non- J/ψ background and inclusive J/ψ background components are assumed to be the same ($\mathcal{A}_{inc}^{bkg} = \mathcal{A}_{non}^{bkg} \equiv \mathcal{A}^{bkg}$). This fit therefore has six free parameters: the yields of the $J/\psi\rho^+$ signal, $J/\psi\pi^+\pi^0$ nonresonant signal, and inclusive J/ψ background components, and the asymmetries \mathcal{A}^ρ , \mathcal{A}^{NR} , and \mathcal{A}^{bkg} .

From the charge asymmetry fit, we obtain $A^\rho = -0.11 \pm 0.12(\text{stat.})$. The signal and background yields obtained from this fit are entirely consistent with those from the branching fraction fit.

The other sources of systematic error on the asymmetry are potential differences in the backgrounds for positive and negative B candidates. The parameters describing the charge asymmetries of the exclusive J/ψ background channels are varied within their uncertainties [9], assuming a 10% uncertainty for the $J/\psi K_1(1270)$ channel for which no measurement is available. The normalizations of the exclusive background channels, and the shape parameters of the inclusive J/ψ background and non- J/ψ background components are varied in turn, and the fit is repeated. The resulting changes to the fitted value of \mathcal{A}^ρ are added in quadrature, and the total systematic uncertainty is found to be ± 0.08 .

In summary, we measure the following branching fractions, where the first error in each case is statistical and the second is systematic: $\mathcal{B}(B^0 \rightarrow J/\psi\rho^0) = (2.7 \pm 0.3 \pm 0.2) \times 10^{-5}$, and $\mathcal{B}(B^+ \rightarrow J/\psi\rho^+) = (5.0 \pm 0.7 \pm 0.3) \times 10^{-5}$. The signals for $B^0 \rightarrow J/\psi f_2$, $B^0 \rightarrow J/\psi\pi^+\pi^-$ nonresonant, and $B^+ \rightarrow J/\psi\pi^+\pi^0$ nonresonant are not statistically significant, thus we set the following upper limits at the 90% confidence level: $\mathcal{B}(B^0 \rightarrow J/\psi f_2) < 4.6 \times 10^{-6}$, $\mathcal{B}(B^0 \rightarrow J/\psi\pi^+\pi^-) < 1.2 \times 10^{-5}$, and $\mathcal{B}(B^+ \rightarrow J/\psi\pi^+\pi^0) < 7.3 \times 10^{-6}$. We measure the charge asymmetry defined in Eq. (1) for the decays $B^\pm \rightarrow J/\psi\rho^\pm$, $\mathcal{A}^\rho = -0.11 \pm 0.12 \pm 0.08$.

The measurements presented here for neutral B decays supersede those from the previous *BABAR* analysis [5], and find a somewhat higher ratio of $J/\psi\rho^0$ to $J/\psi\pi^+\pi^-$ nonresonant decays. Differences with respect to the older analysis are: a substantially larger data set, a two-dimensional fit rather than a one-dimensional fit to $m_{\pi\pi}$, the inclusion of the $J/\psi f_2$ component in the fit, and a more complex treatment of the background. We also present the first observation of the decay $B^+ \rightarrow J/\psi\rho^+$. As expected, we measure the branching fraction for this decay to be approximately twice as large as that for $J/\psi\rho^0$, as the decay channel $B^0 \rightarrow J/\psi\omega$ is expected to occur with the same partial width as $B^0 \rightarrow J/\psi\rho^0$, and there is no equivalent to this in charged B decays. Finally, we find no significant charge asymmetry in $B^\pm \rightarrow J/\psi\rho^\pm$ decays.

We are grateful for the excellent luminosity and machine conditions provided by our PEP-II colleagues, and for the substantial dedicated effort from the computing organizations that support *BABAR*. The collaborating institutions wish to thank SLAC for its support and kind hospitality.
