

Chemical composition and bioactivity of methanolic extract obtained from *Lepista sordida*

Krishnendu Acharya^{1*}, Sandipta Ghosh¹, Rhituparna Biswas¹

¹Molecular and Applied Mycology and Plant Pathology Laboratory, Department of Botany, University of Calcutta, 35, Ballygunge Circular Road, West Bengal, India

The present study aimed at the evaluation of chemical composition and bioactive potential of methanolic extract obtained from *Lepista sordida* in terms of antioxidative and antimicrobial efficacy. The macrofungus is recognized for its high nutritional value and medicinal properties. However, to the best of our knowledge bioactivity of its methanolic extract is yet to be explored. In this investigation, quantitative analysis of mycochemicals revealed the extract contained significant amount of phenolic compounds such as phenols and flavonoids. Ascorbic acid was found in higher amount than β carotene and lycopene which were present in vestigial amounts. A phenolic profile was also determined using high performance liquid chromatography that further confirmed the presence of 10 phenolic constituents in the extract. Furthermore, the extract was subjected for determining antioxidant potential in different in-vitro assays. The findings showed remarkable 2, 2-Diphenyl-1-picrylhydrazyl and ABTS radical scavenging ability which was evident by low EC_{50} values, 330 μ g/mL and 30 μ g/mL respectively. The extract also demonstrated good chelating and reducing ability, an important marker of antioxidant compounds. Antimicrobial screening displayed positive results against *Staphylococcus aureus* and *Escherichia coli*. Altogether, the observations recommend therapeutic application of this mycotaxon on a commercial basis.

Keywords: Antimicrobial. Free radical scavenger. High performance liquid chromatography. Mycotaxon. Mycochemicals.

INTRODUCTION

From ancient past, mushrooms are widely consumed as a delicacy in many Asian and Western countries since they are enriched with high quality proteins, carbohydrates, fibers, minerals, vitamins and since they also possess delicious taste and flavor (Khatua *et al.*, 2017). Recently, in 20th century they are emerging as a potential candidate in the field of alternative medicine. Different groups of bioactive metabolites including polyphenolic compounds, terpenoids, tocopherols, β -glucan are known to be accumulated by this group of fungi that imparts unique therapeutic effects (Boonsong, Klaypradit, Wilaipun, 2016). Therefore they could be directly exploited for mankind due to their immense health promoting benefits as an antioxidant, anticancer, antidiabetic, immune-stimulatory agents.

Medicinal mushrooms are one of the major sources of polyphenols and their derivatives and also recognized as a repository of antimicrobial metabolites (Shen *et al.*, 2017). Literature study implicates phenolic compounds for being solely responsible for several protective effects against free radical induced injuries and microorganisms etc (Wong *et al.*, 2009). Moreover, in recent times most of the synthetic drugs used in treatment of infectious diseases have gradually become ineffective due to nonselective application and harmful side effects. Thereby in present scenario, mushrooms with their reservoir of polyphenols and medicinally promising bio-compounds have drawn great attention from the scientific world with a promise that they could overcome the drawbacks of synthetic antioxidants and traditional antibiotic drugs.

L. sordida is such a mushroom that belongs to the clitocyboid agaric genus (Family-Tricholomataceae), commonly known as flesh-brown blewit. The species was first described by Mycologist Elias Magnus Fries as *Agaricus sordidus* (Thongbai *et al.*, 2017). Widely distributed in Asia, North America and Europe, 8 species

*Correspondence: K. Acharya. Molecular and Applied Mycology and Plant Pathology Laboratory, Department of Botany, University of Calcutta, 35, Ballygunge Circular Road, Kolkata 700019, West Bengal, India. E-mail: krish_paper@yahoo.com

of *Lepista* genus have been recorded as edible from all over the world (Alvarado *et al.*, 2015). Among them majority of the medicinal attributes have been assigned to *L. sordida*. A vast number of studies have been documented regarding its ideal condition of cultivation, especially of the Chinese and Thai strains (Tian, Feng, Zhong, 2003; Li *et al.*, 2014, Thongbai *et al.*, 2017). They are described as a rich source of carbohydrates, essential amino acids, dietary fibers (Hu *et al.*, 2016). In addition, many bioactive metabolites namely diterpenoids (lepistal and lepistol), dioxygenated diketopiperazines, lepidamides A–C, diatretol were isolated from submerged mycelial cultures of the macrofungus (Mazur *et al.*, 1996; Chen *et al.*, 2011). Its water soluble polysaccharides have shown strong anticancer activity against laryngocarcinoma cells that signaled through HMGB1/NF- κ B pathway (Hu *et al.*, 2016). Zhong *et al.* (2013) also demonstrated free radical scavenging and anti-aging effects of an intracellular polysaccharide isolated from submerged mycelial culture of this mushroom. Although there is no report regarding bioactive mycochemical content in methanolic extract of this taxon and free radical scavenging and bactericidal potentials of wild species. Therefore, in the present investigation, we highlight the phenolic profile of the methanolic extract of this mushroom and its concurrent bioactivity so that it will enhance its therapeutic value.

MATERIAL AND METHODS

Chemicals

Acetone, hexane, methanol, aluminum nitrate, sodium acetate, folin-cicolteau reagent, sodium carbonate, oxalic acid, DCPIP dye, ferric chloride, ferrous chloride, ferrozine, potassium ferricyanide, trichloroacetic acid (TCA), 2,2-diphenyl-1-picrylhydrazyl (DPPH), sodium sulfate, ammonium molybdate, 2,2'-Azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS), potassium persulfate, ascorbic acid, ethylene diaminetetraacetic acid (EDTA), trolox, gallic acid, quercetin, nutrient broth (NB), dimethyl sulphoxide (DMSO), *p*-iodonitrotetrazolium chloride (INT) were purchased from Himedia, Mumbai, India.

Test organisms

Bacterial strains that were used as test organisms, *Bacillus subtilis* MTCC Code 736, *Listeria monocytogenes* MTCC Code 657, *Staphylococcus aureus* MTCC Code 96, *Escherichia coli* MTCC Code 68, *Klebsiella pneumoniae* MTCC Code 109 and *Salmonella typhimurium* MTCC

Code 98 were obtained from MTCC, Institute of Microbial Technology, Chandigarh, India. Bacteria were cultured in nutrient agar medium, aerobic condition at 37°C. Before each experiment, subculturing of each strain was carried out in nutrient broth (NB).

Instrument

Bio-Rad iMark™ Microplate Reader (USA) was used for absorbance measurement of 96 well plate. The instrument consists of an eight-channel, vertical path length photometer that reads at specific wavelengths such as 415, 450, 490, 595, 655, and 750 nm in 96-well microtiter plate.

Mushroom collection

Fresh basidiocarps of wild *L. sordida* were collected from Gangetic plains of Murshidabad district of West Bengal. The mushroom was brought to the laboratory for identification and distinguishing micro-morphological features were documented consulting standard literature (Pegler, 1986). A voucher specimen was preserved in CUH herbarium with the accession number CUHAM165 following the protocol of Pradhan, Dutta, Acharya (2015). Fruiting bodies were dried at 40 °C overnight and then ground in a mixer grinder to obtain a fine powder which was stored in a fresh container for further use.

Preparation of methanolic extract

Dried powdered sample was extracted in methanol and after 24 hours solution was filtered through Whatman filter paper, again fresh solvent was added for re-extraction. Final filtrate obtained was kept at 4 °C for further use. Organoleptic characters of the extract were recorded.

Mycochemicals estimation

Freshly prepared methanolic extract was subjected for quantification of phytochemicals. Total phenol content was estimated using Folin-ciocalteu reagent, gallic acid as standard (Singleton, Rossi, 1965). Flavonoid content was measured using Quercetin (5–20 µg/mL) as standard (Adebayo *et al.*, 2012). Result was expressed as µg of quercetin equivalents per mg of extract. Ascorbic acid content was determined by titration against 2, 6-dichlorophenol indophenol dye (Acharya *et al.*, 2015). β -carotene and lycopene contents were estimated as per our previously published protocol (Acharya *et al.*, 2016).

HPLC of methanol soluble extract

The methanolic extract was filtered through 0.2 µm filter and 20 µL of the filtrate was loaded in the HPLC system (Agilent, USA). Separation was done on an Agilent Eclipse Plus C18 column (100 mm × 4.6 mm, 3.5 µm) using a flow rate of 0.8 mL/min at 25 °C. The mobile phase consisted of eluent A (acetonitrile) and eluent B (aqueous phosphoric acid solution, 0.1% v/v). A gradient program was used for elution: 0–2 min, 5% A; 2–5 min, 15% A; 5–10 min, 40% A; 10–15 min, 60% A; 15–18 min, 90% A and absorbance of sample solution was measured at 278 nm (Acharya, Mukherjee, Mitra, 2015).

Antimicrobial assay

Antimicrobial activity of the extract was determined by microdilution method (Stojković *et al.*, 2013). Freshly prepared inoculi of six bacteria were seeded in a 96 well plate at a concentration of 1×10^5 CFU/mL. Reaction mixture consisted of 200 µL of NB, different concentrations of extracts (50–500 µg/mL) and 20 µL inoculum. Positive and negative control was prepared by inoculated growth medium without adding test samples and DMSO respectively. Streptomycin was used as standard. Plate was incubated for 24 hours at 37 °C followed by addition of 40 µL of INT dye (0.2 mg/mL) in each well and further incubation for 30 minutes. IC_{50} value was calculated that indicates the concentration at which 50% bacterial growth was inhibited and compared against standard, Streptomycin.

Antioxidant assays

DPPH radical scavenging assay

DPPH scavenging potentiality of extracts was evaluated by using 0.004% DPPH in methanol solution and different concentrations of extracts (100–500 µg/mL) following the protocol of Khatua, Ghosh, Acharya (2017). The reaction mixture was incubated for 30 minutes followed by measuring the absorbance at 595 nm in microplate reader. Scavenging activity was represented as percentage of inhibition with respect to ascorbic acid standard. EC_{50} values were calculated with the help of calibration curve indicating the concentration where 50% DPPH radicals were scavenged. Percentage of scavenging activity was measured using the following formula:

Scavenging percentage (%): $[A_{DPPH} - A_s] / A_{DPPH} \times 100$.

A_{DPPH} is the absorbance of DPPH solution and A_s is

the absorbance of the solution containing various concentrations of extract.

Chelating ability of ferrous ions

For determination of ferrous ion (Fe^{2+}) chelating ability of the extracts, a standard protocol was followed (Khatua, Ghosh, Acharya, 2017). 200 µL reaction mixtures comprised of 3 nM $FeCl_2$ (5 µL) and different concentrations of extract were prepared separately in a 96 well plate (50–300 µg/mL). Reaction was commenced after addition of 0.12 nM ferrozine (10 µL) and after 10 min incubation; absorbance was measured at 595 nm using microplate reader. EC_{50} values were calculated from graph plotted against EDTA as standard. Results were represented as percentage of suppression of Fe^{2+} –Ferrozine complex formation.

Reducing power assay

Additionally, reducing power of the methanolic extract was examined using the following procedures (Khatua, Ghosh, Acharya, 2017). 10 µL of different concentrations of extracts (60–220 µg/mL) along with respective amounts of water and 0.2 M Na-phosphate buffer, pH 6.6 (25 µL) were mixed with freshly prepared 1% potassium ferricyanide solution (25 µL) and incubated for 20 minutes at room temperature. After that, 85 µL water and 8.5 µL ferric chloride were added in each well separately. Finally, the optical density was determined at 750 nm using same microplate reader as mentioned earlier. Ascorbic acid was used as standard and EC_{50} value was evaluated at the concentration exhibiting 0.5 absorbance value.

ABTS radical scavenging assay

ABTS radical scavenging activity of the methanolic extract was estimated spectrophotometrically following the method of Khatua, Ghosh, Acharya (2017). $ABTS^{\cdot+}$ radical was formed by mixing equal proportion of 7 mM ABTS dissolved in water with 2.45 mM potassium persulfate and then the mixture was kept for 12–16 hours in dark condition at room temperature. Before use, dilution of $ABTS^{\cdot+}$ solution was executed to get an absorbance of 0.700 at 750 nm. Reaction sets (200 µL) were prepared for various concentrations of extract (10–50 µg/mL) and Trolox, a positive control followed by 10 minutes incubation. After incubation absorbance was taken at 750 nm. Percentage of $ABTS^{\cdot+}$ radical scavenging activity was calculated and EC_{50} was determined from calibration curve.

Total antioxidant activity

Total antioxidant activity of the extract was determined as reported by Prieto, Pineda, Aguilar (1999).

3.3 mL reaction mixture contained of 0.3 mL sample solution and 3 mL freshly prepared reagent solution comprising of 0.6 M sulphuric acid, 28 mM sodium sulphate and 4 mM ammonium molybdate. Tubes were incubated at 95 °C for 90 minutes and after cooling down absorbance were measured at 695 nm against blank. Ascorbic acid (1–30 µg/mL) was used to prepare standard curve and values were expressed as the number of equivalents of ascorbic acid.

Statistical analysis

Herein, all results are represented as mean \pm standard deviation of three independent experiments each in triplicates and statistically evaluated using Microsoft® Office Excel (Microsoft®, USA).

RESULTS AND DISCUSSION

Mycochemical composition

Literature studies validated the most effective solvent for extraction of phytochemicals from mushroom is the polar solvent mainly methanol and its extractive yield is also higher compared to other polar solvents (Padalia, Chanda, 2015). Herein methanol is used to extract and quantify mycochemicals present in fruiting bodies of *L. sordida*. The methanolic extract was brown coloured, with an extractive value of 7.8%. Freshly prepared fraction was subjected for quantification of bioactive mycochemicals using standard protocols. Total phenol content was estimated at 17.1 ± 0.14 µg gallic acid equivalent/mg of extract. The extract contained flavonoid accounting for 0.125 ± 0.28 µg quercetin equivalent/mg of extract. Ascorbic acid was also present in notable amount i.e. 2.083 ± 1.08 µg/mg of extract. β -Carotene and

lycopene were found in little amounts (0.052 ± 0.04 µg/mg and 0.045 ± 0.01 µg/mg of the extract respectively). However, our results indicated this methanolic fraction of *L. sordida* is more enriched with secondary metabolites than methanol extract of *Schizophyllum commune* (Acharya, Ghosh, Dutta, 2016), *Lentinula edodes* (Acharya, Mukherjee, Mitra, 2015) as well as Polyphenol-rich extract of *Pleurotus flabellatus* (Dasgupta, Sherpa, Acharya, 2014).

Chromatographic fingerprinting

Furthermore, HPLC profile of the extract was recorded that served as a phenolic fingerprint of the fraction. Chromatogram analysis revealed at least 20 components are present excluding solvent peaks (Figure 1) after scanning at 278 nm. Retention times and respective areas of each peak are given in Table I.

Antimicrobial activity

Due to emergence of antibiotic resistant microbial flora, most of the commercially available antibiotic drugs exploited in treatment of several microbial diseases become ineffective (Ventola, 2015). Searching for alternative drugs of natural sources is of utmost need to combat this crisis. The present investigation showed that the methanol extract of *L. sordida* was an efficient antibacterial agent against *S. aureus*, a Gram positive bacterium, although it did not show any effects against *K. pneumoniae* even after high dose treatment. With respect to Table II, Gram positive bacteria including *S. aureus*, *L. monocytogenes* and *B. subtilis* were more susceptible to the extract as indicated by low IC₅₀ values than Gram negative ones. The result is consistent with diterpenoid lepidial activity as reported by Mazur *et al.* (1996).

19	16.737	13.838
20	16.991	14.679

Antioxidant assay

For determination of antioxidative potentiality of any compounds, one single assay would not be able to confirm accurately an agent's true potential basically for the fact that antioxidant activity entails multiple processes such as reactive radical scavenging, metal chelation, reducing power etc. Therefore in the present investigation, five different in vitro assays were performed to evaluate antioxidative efficacy of *L. sordida*.

DPPH; an organic commercially accessible free radical was utilized as a simple method of screening of free radical scavenging potentiality of test compounds. Antioxidant molecules can effectively scavenge DPPH radical that visibly reflects to the discoloration of violet coloured DPPH solution. Therefore, the more rapidly the colour changes, the more powerful the free radical scavenging activity of the extract. In the present study, methanolic extract of *L. sordida* exhibited excellent scavenging activity that increased upto 71.63% at the higher doses of 500 µg/mL (Figure 2). EC₅₀ value has been presented in Table III, and it depicts methanolic extract of *L. sordida* as a strong antioxidative fraction in comparison with methanolic extract of *L. sordida* (EC₅₀ 9.82 mg/mL) (Heleno *et al.*, 2010) and ethanolic extract of *Entoloma lividoalbum* (EC₅₀ 2.13 mg/mL) (Dasgupta, Rai, Acharya, 2015) and *Macrocybe crassa* (EC₅₀ 1.66 mg/mL) (Khatua, Acharya, 2014).

Furthermore, chelating capacity of the extract was determined by ferrozine assay. The principle is based on interruption of ferrous ion-ferrozine complex production by antioxidant compounds which chelate ferrous ions thus inhibiting free radical generation. In the present study, the methanolic extract demonstrated good chelating activity as the violet coloured complex was maximally inhibited at the highest concentration of the extract (300 µg/mL). Figure 2 depicts that at concentrations of 70, 100 and 300 µg/mL, the fraction exhibited remarkable chelating activity at the rate of 19.47%, 49.8% and 74.03% respectively. In our previous publication, chelating ability of ethanolic extract from *Termitomyces clypeatus* had been recorded (Mitra *et al.*, 2016) which exhibited higher EC₅₀ value of 0.21 mg/mL compared to *L. sordida* (EC₅₀ 177 ± 1.25 µg/mL).

Reducing power is usually categorized as an indicator of antioxidative efficacy of test compounds. It depends on electron donating capacity of compounds that reduce Fe³⁺/ferricyanide complex to Fe²⁺ form (Boonsong, Klaypradit, Wilaipun, 2016). Yellow colored reaction

TABLE II - Antimicrobial activity of methanolic fraction extracted from *Lepista sordida*. Results are represented as IC₅₀ value (mean ± standard deviation; n = 3)

Bacterial types	Bacterial strains	IC ₅₀ value (µg/mL)	Streptomycin (µg/mL)
Gram positive	a) <i>Bacillus subtilis</i>	535.76	5.608
	b) <i>Listeria monocytogenes</i>	288.95	4.68
	c) <i>Staphylococcus aureus</i>	30.6	6.295
Gram negative	a) <i>Escherichia coli</i>	90	5.415
	b) <i>Salmonella typhimurium</i>	658.83	5.092
	c) <i>Klebsiella pneumoniae</i>	Nil	5.294

mixture gradually changes to various shades of green colour denoting reducing ability of test sample as the concentration of sample increases. Figure 2 shows that reducing capacity of the methanolic extract had a strong dose dependent increment, maximum at 220 $\mu\text{g/mL}$ (absorbance-0.62). However the sample exhibited better activity (EC_{50} 160 \pm 0.89 $\mu\text{g/mL}$) than methanolic extract of *Pleurotus sajor-caju* (EC_{50} 1.31 mg/mL) and *P. sapidus* (EC_{50} 2.53 mg/mL) (Jeena *et al.*, 2014).

ABTS radical scavenging assay was performed which is considered as one of the time-saving simple technique to determine free radical scavenging potentials of natural compounds. In this method, directly produced blue-green $\text{ABTS}^{+\cdot}$ radical is reduced to its natural colorless form in presence of antioxidant molecules (Islam, Yu, Xu, 2016). Herein, the methanolic extract of *L. sordida* possessed a remarkable scavenging activity which gradually increased from 29.73% to 65.47% at 20 $\mu\text{g/mL}$ and 40 $\mu\text{g/mL}$ concentrations respectively

(Figure 2). EC_{50} value was found to be comparatively lower indicating strong scavenging activity than methanolic extract of *Pleurotus ostreatus* (EC_{50} 76.63 mg/mL) as reported by González-Palma *et al.* (2016).

Finally, total antioxidant capacity was measured using Phosphomolybdenum method and the value was compared with natural antioxidant ascorbic acid. Results showed that 1 mg of extract was equivalent to 36.25 μg of ascorbic acid.

CONCLUSION

The present study reveals that the methanolic extract of *L. sordida* has an excellent free radical scavenging potency which may correlate with the presence of significant amount of antioxidant compounds such as phenols, flavonoids and ascorbic acid. However, HPLC data served as phenolic fingerprint of this mushroom and confirmed the bioactive properties of the extract. Thus

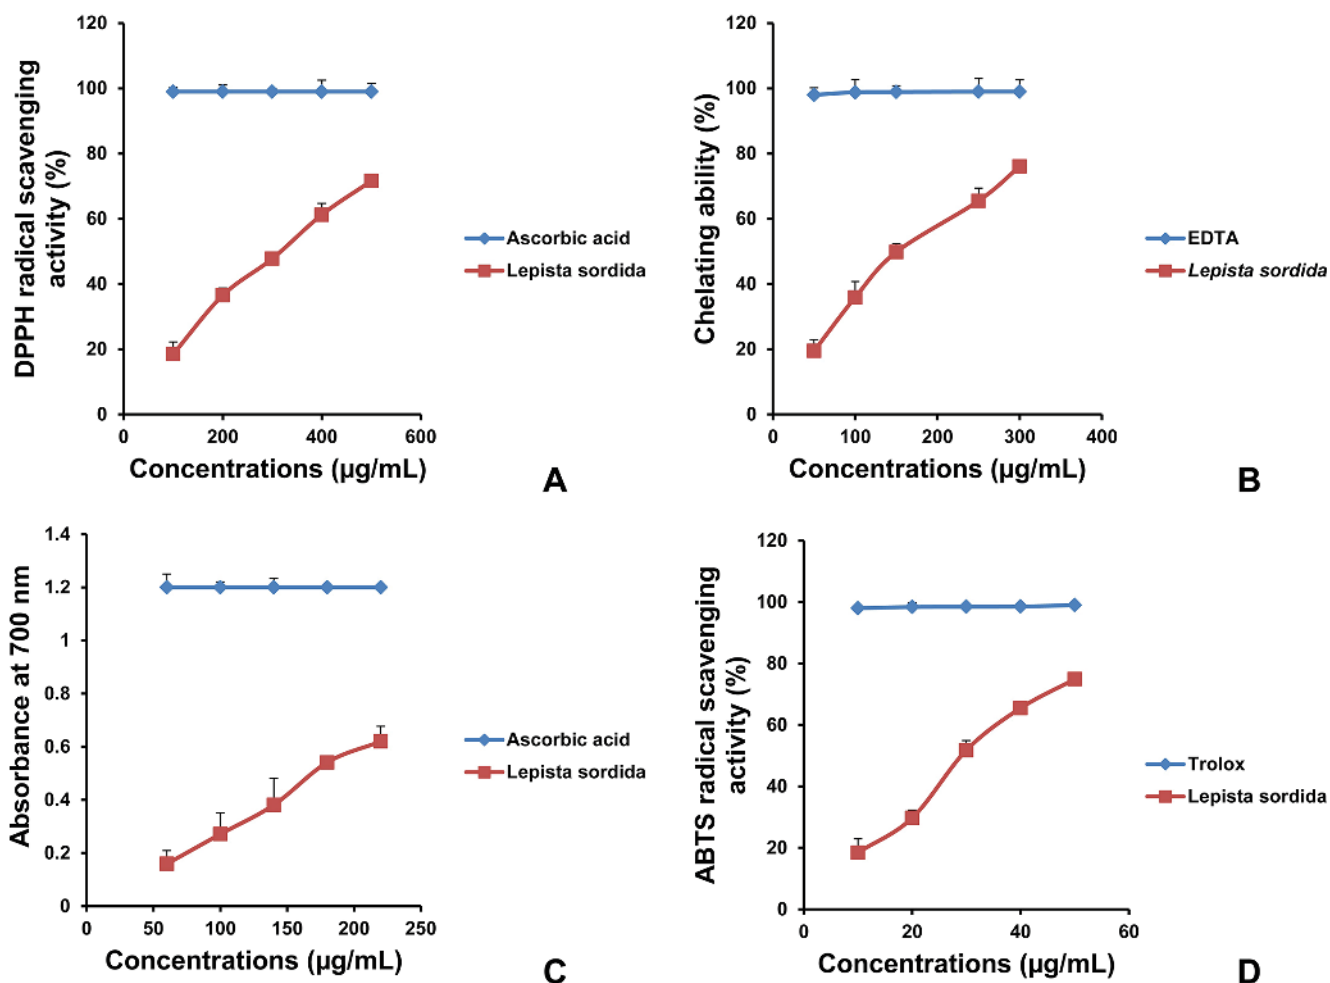

FIGURE 2 - Antioxidant activity of methanolic extract from *Lepista sordida* A) DPPH radical scavenging activity B) Chelating ability C) Reducing power D) ABTS radical scavenging activity.

TABLE III - Antioxidant activity of methanolic fraction extracted from *Lepista sordida*. Results are expressed in EC50 values (mean \pm standard deviations; n=3)

Antioxidant assays	Methanolic extract ($\mu\text{g/mL}$)	Standard ($\mu\text{g/mL}$)
DPPH radical scavenging activity	330 \pm 0.23	7.69 \pm 0.03
Chelating ability of ferrous ion	177 \pm 1.25	11.81 \pm 0.02
Reducing power	160 \pm 0.89	18.74 \pm 0.01
ABTS radical scavenging activity	30 \pm 2.29	3.18 \pm 0.01

the investigation will help to exploit this mushroom as an alternative resource of natural antioxidants to synthetic ones such as BHA, BHT etc that possess harmful effects on human health. Moreover, the extract was also effective against tested gram negative and gram positive bacteria indicating its possible application as potential source of antibiotics.
