Childhood Circumstances and Adult Outcomes: Act II
Douglas Almond, Janet Currie, and Valentina Duque
NBER Working Paper No. 23017
January 2017
JEL No. H4,I14

ABSTRACT

That prenatal events can have life-long consequences is now well established. Nevertheless, research on the Fetal Origins Hypothesis is flourishing and has expanded to include the early childhood (postnatal) environment. Why does this literature have a “second act?” We summarize the major themes and contributions driving the empirical literature since our 2011 reviews, and try to interpret the literature in light of an overarching conceptual framework about how human capital is produced early in life. One major finding is that relatively mild shocks in early life can have substantial negative impacts, but that the effects are often heterogeneous reflecting differences in child endowments, budget constraints, and production technologies. Moreover, shocks, investments, and interventions can interact in complex ways that are only beginning to be understood. Many advances in our knowledge are due to increasing accessibility of comprehensive administrative data that allow events in early life to be linked to long-term outcomes. Yet, we still know relatively little about the interval between, and thus about whether it would be feasible to identify and intervene with affected individuals at some point between early life and adulthood. We do know enough, however, to be able to identify some interventions that hold promise for improving child outcomes in early life and throughout the life course.

The fetal origins literature has been particularly active over the last several years rendering reviews by Currie (2009) and Almond and Currie (2011a, b) somewhat dated. Figure 1 shows the number of papers about “fetal origins” in several leading journals by year.¹

Why does this literature “have legs”? By now, the rudimentary point is familiar. Currie and Hyson (1999) using longitudinal data showed that long-term outcomes seemed to respond to circumstances in utero; Costa (2000) found that chronic health conditions among older men were predicted by early-life infant mortality rates in their natal areas, which can proxy for the disease environment. Papers exploiting natural experiments to show the long-term impact of fetal and

¹ Figure 1 shows the number of annual publications from January 1993 to October 2015 in the Quarterly Journal of Economics, American Economic Review, Journal of Political Economy, Econometrica, Review of Economic Studies, Journal of Labor Economics, Journal of Econometrics, Journal of the European Economic Association, Review of Economics and Statistics, Journal of Human Resources, Journal of Public Economics, American Economic Journal: Applied Economics, Journal of Development Economics, American Economic Journal: Economic Policy, and Journal of Health Economics.

early life shocks such as Almond (2006), Van Den Berg et al. (2006), and Bleakley (2007), are a decade old.

One reason for continued interest is that the large magnitude of the fetal origins effects that have been found, and the short time interval in utero suggest that in principle, Pareto improvements can be made by re-allocating resources from later to earlier in the life cycle. Given the common definition of economics as the study of the allocation of scarce resources (e.g., Blackhouse and Medema, 2009), this literature resonates with a core interest of economists: efficiency. Of course, the separation in time and across people (first the mother then the child) makes it far from obvious how this potentially high-return reallocation of resources can best be achieved.

A second reason for enduring interest in the Fetal Origins Hypothesis (FOH) is that it has proven to describe a surprisingly general phenomenon. Although FOH was first formulated as a specific theory about the effects of prenatal nutritional deprivation on chronic health conditions in adulthood (Barker, 1998), economists have found that a wide range of early life experiences matter and that many other (non-health) outcomes are affected. Outcomes of surpassing interest to economists, including IQ and wages, have been linked to early life influences, as have some newer areas of focus such as personality traits.

This evolving discovery speaks to another area of abiding interest for economics: the debate about nature versus nurture. It has become increasingly clear that we are shaped by many occurrences in early life which interact with our genetic endowments to either help or hinder us in reaching our potential and/or adapting to our environment (Manski, 2011). The FOH literature suggests that it may be possible to respond to entrenched disadvantage by altering the

environment in a way that promotes economic equality (Currie, 2011). Thus, the FOH remains important because it suggests that it may be possible to counter-balance forces leading to greater inequality (such as skill biased technical change) with investments in pregnant women, children, and their environments broadly defined.²

In addition to surveying studies that focus on shocks that occur while the child is in utero, this review considers shocks in early childhood. Angrist and Pischke (2010) herald a “credibility revolution” in which clear *a priori* definitions of treatment and control groups combined with time-series variation in environmental conditions help to generate sharp predictions. The FOH hypothesis lends itself to “severe tests” (Dinardo, 2007) given that the in utero period is very well defined, and children subjected to an external shock in utero can often be compared to similar children born a little earlier or later, who escaped the shock. The beginning and ending dates of the period of “early childhood” are less well defined than the period in utero making it somewhat more difficult to find clean “natural experiments.” It is nevertheless possible to employ compelling identification strategies and we feel the majority of papers discussed in this review employ compelling research designs.

In view of the large number of relevant studies, we organize the review around a series of “handbook” style tables that we present in the supplemental file (which can be found using the link in the abstract page). In lyric opera fashion, the tables briefly summarize each study’s highlights. We also report the datasets used, sample sizes, the empirical strategy employed, main results obtained, and any heterogeneity by subgroup in the tables. We have also tried to express

² In describing “Six examples of the Long-term Benefits of Anti-Poverty Programs”, the White House’s Council of Economic Advisers summarized recent research in this literature by economists, noting:

Economists have traditionally argued that anti-poverty policy faces a “great tradeoff” — famously articulated by Arthur Okun — between equity and efficiency. Yet, recent work suggests that Okun’s famous tradeoff may be far smaller in practice than traditionally believed and in many cases precisely the opposite could be the case.

the main effects both as a percent with respect to the outcome mean (when the outcome mean was provided in the paper) and in terms of a standard deviation (when the outcome's standard deviation was provided). To some extent, reporting estimates in % and in SD facilitates the comparison of the effects across studies when these focus on a similar outcome (e.g., test scores).

Consistent with the broader trend in economics, many of these papers pay particular attention to the use of large-scale administrative datasets. Beyond reducing measurement error and recording additional outcomes, the use of administrative data can help mitigate problems of selective attrition from surveys and the large sample sizes contribute statistical power to detect milder treatments. These tables largely speak for themselves, so rather than walk through them, we focus in the text on a few studies from each table in an attempt to draw some general lessons from the existing literature and to identify promising areas for future research.

We begin by providing a conceptual framework for our review in Section 1. This framework emphasizes the child's human capital accumulation process and parent's optimal investment decisions in the presence of in-utero and early childhood shocks given production functions and budget constraints. The framework can be used to elucidate potential pathways that underlie the empirical findings that we observe in the literature. Section 2 then provides an overview of the literature on the importance of "mild" shocks in the early years. In addition to new evidence about the wide range of factors that matter to child development, an important theme that emerges is that there is often considerable heterogeneity in the effects of specific shocks. Some of the heterogeneity in the effects of shocks may be due to parental responses that either exacerbate or mitigate the effects. Hence, we will also consider the evidence documenting some of these responses and their impacts in Sections 3.

In addition, a small but growing literature exploits situations where there are “two shocks” in order to either separately identify the effects of initial shocks and responses to them, or to investigate potential interactions between various types of shocks. Since this is an interesting and novel development that resonates with the theory of capacity formation (Heckman, 2007), some of these studies are highlighted in Section 4.

As discussed above, economists are beginning to investigate policy responses to the FOH. Recent contributions to this literature are reviewed in Section 5. A striking feature of the most recent literature is that the growing accessibility of administrative data has allowed researchers to conduct policy evaluation by linking current adult outcomes with past “exposures” to policies in a way that was not possible previously.

One practical difficulty with this approach is that it takes many years to see the effects of fetal or early childhood shocks on adult outcomes while timelines for policy decisions are typically much shorter. Thus, one of our conclusions is that it would be extremely useful to know more about the “missing middle” years, and whether long term effects can be predicted using indicators in early and middle childhood. This question is explored in Section 6. We summarize our impressions of the literature and its future directions in Section 7.

Because the literature is growing so rapidly and in so many directions, this review will not do justice to it all. To make the review more tractable we focus mainly on studies that appeared after our previous reviews were published, and we do not do justice to the “disaster” literature which relies on lethal natural catastrophes such as famines, pandemics, wars, and hurricanes, as natural experiments. Although these papers were very important in the emergence of the FOH, most economists now accept that disasters early in life are likely to have negative

long-term effects on survivors, i.e., that shocks which are “extreme enough” are likely to have persistent effects. Moreover, the fetal origins perspective will never be pivotal in a cost-benefit analysis of measures designed to forestall such disasters.³ Even without the benefit of the recent economic and scientific evidence on the FOH, those suffering disaster often acted in a way to shield pregnant women and young children (such as by giving them larger food rations in a famine). Third, the long term effects of events that involved high mortality can be difficult to discern given the possibility of mortality selection. If the individuals most vulnerable to catastrophe die, then the remaining population could possibly be stronger on average. Selection can be a particular problem when risk of death is higher for groups with lower socioeconomic status, as it often is.

We will also neglect most of the research on conditional cash transfers, in part because it have been reviewed elsewhere (see for example, Fiszbein and Schady, 2009). In addition to these deliberate omissions, we will undoubtedly omit important studies by mistake, given how active the research area has become.

Section 1: Conceptual Framework

Following Heckman (2007), the production technology we consider is a two period Constant Elasticity of Substitution (CES) function:

$$h = A \left[\gamma (\bar{I}_1 + \mu_{1g})^\phi + (1 - \gamma) (I_2 + \mu_{2g})^\phi \right]^{1/\phi} \quad (1)$$

³ We do not intend to suggest that insight and nuance cannot be gleaned from the analysis of such events. For example, Anttila-Hughes and Hsiang (2013) study natural disasters and show that the short-run mortality effects are followed by arguably more important future disinvestments which occur with a lag and kill girls.

where h denotes health or human capital as assessed after childhood, A represents factor productivity, and \bar{I}_1 and I_2 are the investments made in the first and second periods (e.g., parental investments). The first childhood period is denoted with subscript 1 (e.g., in utero) and the second period of childhood (e.g., preschool years) with subscript 2.⁴ A bar superscript indicates that the first period investment is already set, and what is under consideration is the second period investment.

Following Currie and Almond (2011b), we assume that μ_{1g} is an exogenous shock to first period investments (e.g., during pregnancy) and μ_{2g} is an exogenous shock to second period investments (e.g., during pre-school years). The g subscript follows from the fact that exogenous shocks in observational studies typically appear at the group level, whereas the other components of investments, \bar{I}_1 and I_2 may vary at the level of the individual child. In general, we will consider the effect of investment shocks (μ_{1g} and μ_{2g}) holding fixed the child-specific investments during the first period of childhood. If we also hold fixed second period investments (i.e., \bar{I}_2 instead of I_2), then we might consider impacts from shocks on h to be “biological” (Royer, 2009). The parameter γ , where $\gamma \in [0,1]$, represents the weight each childhood period receives in the production of adult health (or more generally, adult human capital).⁵ The parameter ϕ , where $\phi \in (-\infty, 1]$, denotes the extent to which investments in different periods are substitutes or complements, often a key question determining the efficacy of interventions.

We assume that parents make the investment decisions for their (only) child.

Investments are costly, and are valued insofar as they improve h . The effects of investments on

⁴ For simplicity, we consider only two childhood periods, however, this framework can be extended to any number of periods (Heckman, 2007).

⁵ γ is the “capacity multiplier” in Heckman (2007).

h are traded off against parental consumption, i.e., parents maximize their utility, $U = U(C, h)$, which is increasing in both arguments. Parents have a budget constraint (expressed in monetary units) of:

$$Y = p_c C + p_I I_1 + p_I I_2 / (1 + r),$$

where Y denotes family income, p_c and p_I are the market prices of consumption and investment, and r is the interest rate. We assume a Cobb-Douglas utility function of the form:

$$U = (1 - \alpha) \log C + \alpha \log h, \quad (2)$$

and consider how the production technology can shape the observed investment response. In particular, we consider two “extreme” production technologies which have polar opposite predictions for the investment response. The first special case is one of perfect substitutability of investments. If $\phi = 1$, then production technology simplifies to:

$$h = A[\gamma(\bar{I}_1 + \mu_{1g}) + (1 - \gamma)(I_2 + \mu_{2g})]$$

and optimizing parents set:

$$\delta U / \delta C^* = \delta U / \delta h \cdot \delta h / \delta I_2^* (1 + r) / p_I.$$

So under this scenario:

$$\frac{1 - \alpha}{C^*} = \frac{\alpha}{h} A(1 - \gamma)(1 + r) / p_I$$

$$\frac{1 - \alpha}{y - p_I \bar{I}_1 - p_I I_2^* / (1 + r)} = \frac{\alpha(1 - \gamma)(1 + r) / p_I}{\gamma(\bar{I}_1 + \mu_{1g}) + (1 - \gamma)(I_2^* + \mu_{2g})}$$

$$I_2^* = \alpha(y - p_I \bar{I}_1)(1 + r) / p_I - (1 - \alpha)(\gamma / (1 - \gamma))(\bar{I}_1 + \mu_{1g}) - (1 - \alpha)\mu_{2g}$$

$$\frac{\delta I_2^*}{\delta \mu_{1g}} = -\frac{(1-\alpha)\gamma}{(1-\gamma)} < 0.$$

If the μ_{1g} shock is positive (e.g., prenatal Food Stamps), then optimized postnatal investments fall in response. If μ_{1g} is negative (e.g., prenatal stress), then postnatal investments increase in response. That is, period 2 investments are compensatory. When investment responses are compensatory, reduced form analyses of the impact of μ_{1g} will tend to understate biological effects (Royer, 2009).

Following Heckman (2007), we now consider the opposite extreme of perfectly complementary investments:

$$h = A \text{Min}[\gamma(\bar{I}_1 + \mu_{1g}), (1-\gamma)(I_2 + \mu_{2g})].$$

Now optimizing parents⁶ set:

$$\gamma(\bar{I}_1 + \mu_{1g}) = (1-\gamma)(I_2^* + \mu_{2g}),$$

so

$$\frac{\delta I_2^*}{\delta \mu_{1g}} = \frac{\gamma}{1-\gamma} > 0.$$

The period 2 investment response is now reinforcing. Attempting to ameliorate a negative prenatal shock is completely ineffective, so it is optimal to match period 1 investments (subject to weighting by γ) but consume the rest.

The takeaway from these two examples is that whether parents reinforce or compensate shocks can depend on the production technology. Above, we have assumed an “intermediate” substitutability in parental preferences between consumption and their child’s h : Cobb-Douglas.

⁶ For whom period 1 investments are “low”, i.e., $\delta U / \delta C^* < \delta U / \delta h \cdot \delta h / \delta I_2^* (1+r) / p_1$.

By a similar argument, the substitutability of consumption and child outcomes h will also govern the response to early childhood shocks. That said, we might suspect that parameters of parental preferences are particularly difficult to modify.

We might think that in addition to low income, y , poor families face restricted access to production technologies. Given a productivity factor $A' < A$ for disadvantaged families, we would see worse child outcomes for equivalent income and investments. It is also possible that poor families have different values of γ and ϕ , which would generate more nuanced predictions for investments and child outcomes.

There have been few attempts to estimate this underlying production function (1), in order to directly measure the key parameters ϕ and γ , presumably because of the detailed data necessary and the strong assumptions which must be made in order to render the production function simple enough to be estimable (Cunha and Heckman, 2008; Cunha, Heckman, and Schennach, 2010). However, arguably this underlying framework serves to motivate, guide, and interpret the more reduced form and observational work that is discussed below.

The framework also lays bare the multiple mechanisms that can underlie a given empirical result. For instance, if we observe that parents do or do not make compensating later life investments in a child who suffered from an early life shock, is this because of parental preferences, budget constraints,⁷ or the production function they are facing? Answering this question is important because without a knowledge of the mechanisms and responses, a policy designed to address this issue will be a shot in the dark.

⁷ See page 1330 (bottom) and footnote 7 of Almond & Currie (2011b).

Similarly, given the different pathways through which a child's outcomes can be affected, it is not surprising to see pronounced heterogeneity in the effect of many shocks by parental education, income, and other indicators of socioeconomic status (such as race or gender in some contexts). Subgroups may be more or less exposed to correlated shocks that interact with the "primary" shock considered, either to magnify or to dampen its effect. And even within finely-sliced subpopulations, the same group-level shock can yield varying individual exposures. For example, a house that is airtight may let in less air pollution than a neighboring house that is drafty. Third, families have differential access to knowledge and resources that can be used to offset the effects of negative shocks. For instance, while some individuals may have access to credit markets or savings, others may be credit constrained. They may also have different preferences for such intervention. For example, in communities where gender discrimination is the norm, parents may not endorse interventions targeted to girls. Finally, children of low socioeconomic status may simply be located at a steeper portion of the production function, yielding a larger effect of a shock of any given size (Almond and Currie, 2011b).

Even our focus on the missing research on the "middle years" can be seen as a response to the difficulties involved in understanding the underlying production function for human capital. If it could be shown that outcome measures in middle childhood satisfied the "exclusion restriction" (that early childhood impacts adult outcomes only *through* observed outcomes in the middle years), this would greatly simplify the data requirements necessary to estimate a structural production function.

We should acknowledge that our stylized framework does not lend itself to considering dynamic complementarities -- the idea that "skill begets skill," or alternatively that stocks of

capacities acquired by period t-1 may make investment in period t more productive (Heckman, 2007). Nor does it do justice to “self-productivity” (Heckman, 2007) – which includes the idea that a given dimension of capacity may also affect the accumulation of another, distinct dimension.⁸ For example, cognitive capacity might promote health (or vice versa). Were we to “force” dynamic complementarities into (1) and consider $\frac{\delta h}{\delta \mu_{2g}} / \frac{\delta h}{\delta \mu_{1g}}$, for instance, one would find that the interaction of such shocks is always positive (which departs from what some of the recent empirical literature finds as discussed below). Additionally, dynamic complementarities are defined by Heckman (2007) in terms of the return to investments and how they vary with the baseline *stock*, which is absent from our stylized model. Thus, we will not attempt to model dynamic complementarities here but merely reiterate Heckman’s (2007) definition, namely:

$$\delta^2 f_t(p, \theta_t, I_t) / \delta \theta_t \delta I_t$$

where f is monotone increasing in its arguments, twice continuously differentiable, and concave in I , p represents parental capabilities, and θ_t represents (a vector of) child capabilities. Heckman assumes that dynamic complementarities are positive. With instruments for both the baseline stock of human capital and for endogenous subsequent investments, we could shed light on the magnitude of dynamic complementarities without making assumptions about their sign or functional form.

In practice, it is often not empirically possible to distinguish between dynamic complementarities, self-productivity, and the possibility that parents (or society) invest more (or less) in children with higher baseline stocks of human capital in unobserved ways (e.g., Malamund, Pop-Eleches, and Urquiola, 2016). Nevertheless, distinguishing among these

⁸ Along with “mechanical” effects on the same dimension.

alternatives remains conceptually important because the source of heterogeneity in the dynamic effects of shocks has implications for the effectiveness of remediation, and specifically, whether investments later in childhood can reduce or eliminate damage originating from the prenatal or early childhood period. For instance, if a child has cognitive difficulties as a result of being premature, a parent may respond by spending more time with the child, reading to them and assisting with homework. We may wish to examine the effects of these interventions, but the interventions themselves are endogenous to the child's state. Moreover, while we would like to be able to consider each potential investment as a stand-alone intervention, in reality many aspects of the environment are in flux at any point in time, and different types of investments may complement or substitute for each other. A few studies that attempt to address dynamic complementarities are discussed in Section 4 below, and illustrate the challenges researchers face. We begin below with the simpler case of single shocks experienced in early childhood.

Section 2: Make Mine Mild

Events and circumstances that are commonly experienced can have lasting effects on children's trajectories. For example, there is growing consensus that relatively mild nutritional deprivation at critical periods can seriously impair fetal and child development. In terms of our conceptual framework, both $\delta h / \delta \mu_{1g}$ and $\delta h / \delta \mu_{2g}$ may be sizable, even when the shock considered is small in magnitude relative to total investments or short in duration. Critically, "mild" prenatal shocks are much more common than extreme ones like famine. Table 1 summarizes much of the recent literature about mild shocks, which are divided into several categories including: nutrition, stress, disease, pollution, weather shocks, and alcohol and tobacco. The last column reports on heterogeneity in the estimated effects on different groups, a

format that is followed in all the Tables that follow. With some exceptions, these papers aim to capture the biological effect of early-childhood shocks, implicitly assuming that second period investments are unresponsive to the shocks and fixed ($I_2 = \bar{I}_2$).

a) *Nutritional Shocks*

Panel A of Table 1 summarizes some of the recent literature on nutrition-related shocks. Fasting is of broad interest as roughly three-quarters of the world's 1.6 billion Muslims spent some portion of the *in utero* period during Ramadan.⁹ Almond and Mazumder (2011), Almond, Mazumder, and Van Ewijk (2015), Hoffman (2014), and Greve, Schultz-Nielsen, and Tekin (2015) all study the effects of Ramadan fasting during pregnancy. Ramadan cycles through the calendar, enabling the effects of Ramadan fasting to be separated from seasonal variation in nutrition. Moreover, most people break their fast at sun down so that the fasting is only for a limited period of time during the day. Nevertheless, this mild and brief nutritional deprivation appears to have effects on sex ratios (reducing the number of boys who appear to be more likely to be miscarried). For example, there are large effects on sex ratios among children of Arabian descent in Michigan. Perhaps surprisingly in view of relatively modest effects on birth weight, prenatal Ramadan exposure is estimated to have pronounced effects on adult outcomes in a wide variety of settings (e.g., Uganda, Iraq, Indonesia, England, and Denmark), including to educational attainment, test scores, adult anthropometrics, mental disability, and wealth measures.

⁹ Almond, Mazumder, and Van Ewijk (2015) speculate that meal skipping, dieting, and morning sickness may all exert similar effects in non-Muslim populations. For example, Almond, Edlund, Joffe, and Palme (2016) find that severe morning sickness also reduces the likelihood of male birth in Sweden.

Likewise, positive nutrition-related shocks can also have substantial effects even when relatively mild. For example, Linnemayr and Alderman (2011) examine nutritional supplementation for pregnant women and 0 to 3 year old children in Senegal and find that supplementation during pregnancy has a significant effect on the weight-for-age of toddlers, but that post-birth supplementation had little impact, suggesting the uniqueness of the in utero period (a common refrain in the literature). Two papers by Feyrer, Politi, and Weil (2013) and Adhvaryu et al. (2016) build on Field, Robles, and Torero's (2009) ground breaking study of the effects of iodine deficiency in Kenya. The more recent studies use historical data about the rollout of iodine fortification in the U.S. Because the rollout took place at different times in different places, it is possible to identify the effect of early exposure and to show that it improved both female labor force participation and the probability that male World War I recruits were assigned to the Air Force (a marker for ability). They thus provide additional evidence that relatively mild nutritional deficiency can have large negative long term effects even in otherwise high-resource settings.

Adhvaryu et al. (2016) also analyzes measures of parental investments in children, albeit coarse ones, and find evidence that postnatal investments responded to the shock. In particular, they argue that postnatal vaccinations and breastfeeding behaviors reinforced the prenatal shock, i.e., $\frac{\delta l_2^*}{\delta \mu_{1g}} > 0$, so their reduced form estimates overstate the biological effect. As discussed above (and further in Almond and Currie, 2011b), to the extent that period 1 and period 2 are complements, there are stronger tendencies for parents to reinforce endowment shocks.

Ludwig, Rouse, and Currie (2013) show that maternal weight gain during pregnancy predicts childhood obesity in the context of sibling fixed effects models. This study is based on

birth certificates for several entire cohorts of children born in Arkansas, which were linked to “body mass index (BMI) report cards” issued by the schools. It is one of an increasing number of studies that show how new access to large-scale administrative data sets can shed light on FOH questions.

Fitzsimons and Vera-Hernandez (2014) use a novel instrumental variables strategy for postnatal nutrition, focusing on non-C-section births to U.K. women. They note that mothers of infants born on weekends are less likely to receive breastfeeding instruction, and are correspondingly less likely to go on to breastfeed. Using this variation, they find large effects of breastfeeding on cognitive development. However, the IV approach involves strong exclusion restrictions, in this case that there is nothing else about being born on a weekend (or about having a scheduled C-section) that might lead to poorer outcomes (such as different preferences, inferior nursing care, or less access to specialists).

As a group, these studies support the hypothesis that relatively ordinary variations in nutrition (positive and negative) that are within the experience of many contemporary families even in rich countries like the U.S. and the U.K., have the potential to impact children health both at birth and in the longer term.

b) Prenatal Maternal Stress

Panel B of Table 1 focuses on the impact of maternal stress during pregnancy on fetal outcomes. While the idea that excessive stress has negative health effects is widespread, it is difficult to assess. Cortisol, the most common biometric measure of stress, is not available in most health datasets and also varies widely over the course of a day, which even longitudinal cortisol data do not solve *per se*. In the absence of a direct measure of stress, the most common

approach in the literature is therefore reduced form: Evaluating whether an exogenous event that is likely to have caused maternal stress can be shown to have affected children.

Currie and Rossin-Slater (2013) identify women in Texas who lived in the announced potential path of major hurricanes during pregnancy. It is important to note that most of these women were not in the end affected by the hurricane, so this is not a disaster study in the usual sense in that it is possible to separate the effect of stress from the direct economic or health effects of the event. They highlight an issue that often arises in the fetal effects literature, which is that infants with longer gestations are more likely to have been exposed to any periodic shock because they have a longer exposure window. Since infants with longer gestations are healthier, other things being equal, this mechanical relationship tends to bias the estimated effect of shocks towards zero. They use a sibling fixed effects framework to compare affected to unaffected children and they address maternal mobility, an issue that frequently arises in a sibling fixed effects framework. The problem is that mothers may well respond to a shock by moving. In that case, changes in locational characteristics or exposure between the siblings are endogenous to the shock. This issue is addressed by instrumenting actual exposure with measures of “potential exposure” created by assuming that mothers stay in the same place that they were first observed, and that all gestations last exactly nine months. This counterfactual exposure is in fact highly correlated with actual exposure because most mothers do stay in the same place, and most gestations do last nine months. They conclude that stress increases the probability of an abnormal condition of the newborn, but they found no effects on the incidence of low birth weight or gestation length, two of the more common measures of fetal health.

Persson and Rossin-Slater (2016), and Quintana-Domeque and Rodenas-Serrano (2016) study the effect of more severe emotional shocks including, the death of a family member in Sweden, and terrorist attacks in Spain, respectively. The former uses Swedish registry data to follow affected children up to age 30. An important innovation of their study relative to some earlier work on the same question is that they compare mothers who lost a family member while pregnant, to mothers who lost a family member in the year after birth. Since families of lower socioeconomic status are more likely to lose family members, and since losing a family member could well have an economic impact, this design is cleaner than comparing mothers with a death in the family to mothers without such an event. While the effects on birth weight are small overall, they appear to be concentrated in the lower tail of the distribution, with a 20% increase in the incidence of low birth weight (birth weight less than 2500 grams). In a second contribution, they are able to follow affected infants into adulthood, and they find negative effects on mental health outcomes measured using prescription drug data. For instance, affected individuals are 23% more likely to use ADHD medication, and 9% more likely to use antidepressants as adults. Quintana-Domeque and Rodenas-Serrano also find small but significant effects of terrorist attacks in Spain on overall birth outcomes.

Lee (2014) asks whether the grandchildren of women who suffered a severe stress are less healthy? This is a particularly exciting direction for future work, given that thus far, there is not a great deal of research on intergenerational effects of in utero shocks in humans, although they are known to exist in animal models. In this case the initial shock is was a massacre of civilian demonstrators by the civilian military. He finds small but significant effects on the incidence of low birth weight and prematurity in the grandchildren, with the largest impacts for grandmothers who suffered the shock during the second trimester that the mothers were in utero.

Aizer, Stroud, and Buka (2016) have made an exceptional contribution to this literature because the data they use (which was collected by a consortium of perinatal centers in the 1960s) actually includes measured stress during pregnancy using cortisol. The data set includes a large number of sibling pairs, so that it is possible to conduct mother fixed effects analyses. They find that infants exposed to higher cortisol levels during pregnancy have up to 1 year less school at age 7 than their siblings, indicating that they have been delayed in starting school or held back. Given rich background information on the mothers, this study is also able to ask which infants are most affected by higher maternal stress levels? They find that children born to less educated mothers suffer larger impacts of exposure to a given cortisol level, suggesting that perhaps there were fewer resources available to buffer the impact ex-post.

We have included Aizer's (2011) study of the impact of assault (overwhelmingly due to domestic violence) in this Section of the table even though domestic violence can have direct effects on fetal health in addition to causing maternal stress. Our justification for doing so is that domestic violence is quantitatively important and vastly understudied as a source either of stress or physical injury. The study is based on California hospital discharge data linked to birth records. Variation in the probability of assault is induced by the strengthening of laws against domestic violence, which occurred at different times in different California counties. She finds that domestic violence has a large negative effect on birth weight. Since women of lower socioeconomic status are more likely to be assaulted, violence is therefore an additional cause of disparities in birth outcomes.

c) Infectious Disease

Panel C of Table 1 deals with recent evidence about the effects of disease. Some diseases that have only mild effects in adults are known to have devastating effects on a developing fetus (e.g., Rubella, Zika), while others, like pandemic influenza killed millions and have also been shown to have effects on fetuses in utero. Recent studies focus on the related questions of whether milder diseases can have serious effects; whether the effects of early life exposure to disease are long-lasting; and whether there are spillover effects of disease eradication to children who were not directly targeted. The studies we summarize cover a wide range of settings, from impoverished areas of developing countries, to the historical U.S., to modern Denmark.

The studies by Baird, Hicks, Kremer, and Miguel (2016) and Oizer (2014) build on the famous “worms” paper of Kremer and Miguel (2004) in which the authors investigated the effect of giving children de-worming medication on school attendance and on whether neighboring children were infected with parasites. The new studies ask (respectively) how the effect of deworming affects outcomes of affected children 10 years later, and whether other children benefited from the deworming of their neighbors. Significant and positive effects of deworming are found on virtually all outcomes examined. Unfortunately Oizer does not examine exactly the same outcomes as Baird et al., so it is hard to compare the effects on index children to those on their neighbors, but in keeping with the original paper, deworming initiatives definitely appear to be very cost-effective.

Bhalotra and Venkataramani (2013) and Beach et al. (2016) focus on water borne diseases in Mexico in the 1990s, and in early 20th century America, respectively. The former examine the effect of a clean water reform in Mexico in 1991, which reduced the incidence of water borne diseases, including diarrhea, one of the most common causes of mortality and

morbidity among infants. Beach et al. (2016) use typhoid mortality rates as a proxy for water quality. Bhalotra and Venkataramani find significantly positive but quite small effects of the reduction in water-borne diseases on test scores at ages 9-15. These estimates may understate the effect of clean water given improved survival of the weakest infants, who may end up with low test scores for reasons unrelated to water-borne disease. The Beach et al. estimates appear to be larger: They estimate that moving from the top of the typhoid distribution to eradication would increase educational attainment in surviving children by 1/3 of a year and increase earnings by 4%. This larger effect is unsurprising given that typhoid is at the extreme end of potential severity of water-borne contaminants and many of the contaminants addressed by the water campaigns studied by Bhalotra and Venkataramani would have caused less severe disease. Thus, a possible interpretation is that more severe shocks have a greater impact than less severe shocks but with only two data points it is impossible to say much more about the shape of this relationship.

Venkataramani (2012) builds on work by Bleakley (2010) and others on the long-term effects of malaria. He finds large effects of malaria eradication in the birth year, consistent with those previous studies. Currie and Schwandt (2013) focus on a much milder and currently more common disease: Seasonal influenza. While Almond (2006) showed that the Spanish flu epidemic of 1918 had long lasting effects, it was a killer disease. Currie and Schwandt show that even a relatively mild disease such as seasonal influenza can have negative long term effects if a fetus is exposed at the wrong time during pregnancy. They show that in the contemporary northeastern U.S., infants conceived in May have a much higher probability of preterm delivery (and hence of low birth weight) than infants conceived at other times because they come to term

at the height of the flu season. Moreover, the H1N1 flu season of 2009 was earlier and more virulent than usual and the spike in prematurity was correspondingly earlier and larger that year.

Schwandt (2016) and Ward and Phipps (2014) follow up on these observations by examining the long-term effects of exposure to flu in utero in Denmark and Canada, respectively. Schwandt examines rich individual longitudinal Danish registry data about women who were hospitalized with influenza and follows their children into adulthood. He finds that earnings are 10% lower for affected individuals, and that they are much more likely than others to be dependent on welfare. These long-term outcomes are driven by maternal admissions during the 2nd and 3rd trimester. Ward and Phipps (2014) exploit province-level data on influenza rates to identify the effects of exposure. They do not find any overall effect of an additional week of flu exposure during the pregnancy, but do find a small effect of additional weeks of exposure during the 1st trimester on test scores and on the probability of having a chronic condition. Given that the richness of the Schwandt data it seems that for now, the presumption should be that his conclusions about the timing of the impacts are more likely to be correct. However, the larger message is that millions of children may be harmed in utero by exposure to relatively mild diseases even in rich countries.

Bhalotra and Venkataramani (2015) examine the long-term impact of the introduction of sulfa drugs in 1937, which reduced pneumonia mortality but presumably also had positive effects reducing morbidity.¹⁰ Combining historical data with the U.S. population Census, cohorts who were exposed to sulfa drugs in their infancy attained 0.1 more years of schooling, were 1.5% more likely to graduate from high school, more likely to be employed (0.4%), and earned higher

¹⁰ An earlier paper Jayachandran, Lleras-Muney, and Smith (2010) established that the introduction of these drugs did indeed lead to large declines in mortality from causes such as infections after child birth and pneumonia. Bhalotra and Venkataramani focus on the effects of the introduction on cohorts of children at older ages.

wages (1.5%). Long-term benefits varied for African-American men who were exposed to different levels of segregation in their state of birth, suggesting that despite a strong economic climate (better early life conditions), institutional environment affects the rewards to investments in human capital.

d) Pollution Exposure

The last few years have seen an explosion of research on the effects of pollution in early life, much of which is summarized in Panel D of Table 1. Certain pollutants are well measured in developed countries, exhibit variation over time and across small areas, and have published thresholds which lend themselves to asking whether pollution below the threshold can also be shown to have an adverse effect. Moreover, many sources and types of pollution have been increasingly well documented in recent years, and have discrete beginning and ending dates (such as pollution due to industrial plant openings or closings) that assist identification.

Relative to the literature discussed in our earlier reviews, much of the newest literature focuses on documenting the long-term effects of fetal or early childhood exposures, often relying on newly available large-scale administrative data sources to track children over time. For example, Isen, Rossin-Slater, and Walker (2015) look at the effects of reductions in air pollution due to the Clean Air Acts of 1970 on the employment and earnings of adults who were affected in very early childhood. The Clean Air Acts (CAA) mandated that pollution reduction measures be implemented in counties that were above thresholds for target pollutants. Counties just below these thresholds were not required to clean up. The legislation thus lends itself to analysis using a regression discontinuity framework. In order however to examine outcomes, it is necessary to

merge data from several large administrative data sets, some of which are held in Census data centers.

Specifically, they start with the Census Bureau's Longitudinal Employer Household Dynamics (LEHD) file, which records a worker's unemployment insurance covered earnings each quarter. The authors focus on 24 states that appear continuously in the LEHD and on individuals who were born in these states. The payoff to all this careful data work is that the authors are able for the first time to link air pollution changes around the time of birth to adult earnings and employment. They find an estimated gain of \$4,300 in earnings per person for a total of \$6.5 billion (2008 dollars) in gains.

Another focus of the literature on pollution and early childhood is to ask whether there is heterogeneity in the effects of pollution. There are many reasons to expect disparate impacts of the same potential exposures. For example, more educated people may be more knowledgeable about ways to protect themselves (i.e., have access to a different production function), or may be more likely to take measures that compensate for the harmful effects of pollution (perhaps because of looser budget constraints). They may even be more likely to move away from known pollution sources while the child is still young (Currie, 2011). Richer people may live in housing that insulates them from the effects of pollution, for example, by having houses that are more airtight, or houses that are physically located slightly further from sources such as freeways or factories.

The literature does generally find more negative effects of pollution on more disadvantaged people, whether disadvantage is defined in terms of minority race, income, or education. The only study in Table 1 that finds the opposite is Black et al. (2014) who study the effect of radioactive fallout from nuclear tests on Norwegians born in the 1950s and early 1960s.

In this one case, they find that the effects of potential exposure are greater for the more educated, perhaps because people were unaware of the danger and more educated people were more likely to spend time out of doors (echoing earlier findings by Lleras-Muney for ozone, 2010).

Billings and Schnepel (2015) offer some evidence that the negative effects of early-life pollution exposure might actually be reversed with appropriate interventions, which can be interpreted as evidence about the substitutability of investments in different life periods. The authors show that children who were lead poisoned in Charlotte, North Carolina, and who also received an intense intervention comprised of education for caregivers, lead remediation services, nutritional and medical assessments, and other nutritional benefits from the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), experienced reductions in antisocial behavior and substantial improvements in school performance relative to peers who did not receive these services because they had slightly lower blood lead levels. Since we know that the physical effects of lead are irreversible (once deposited in the brain for example, lead tends to stay there), this result offers hope that compensation for early life insults is possible even when the physiological effects of such insults cannot be reversed.

e) Weather and Climate Change

With increasing scientific consensus about the reality of human induced global warming, economists have responded to concerns about the short and long term effects of climate change on young children. These studies generally extrapolate from what is known about the effects of short-term variations in weather, including periods of high temperature, variations in the amount of sunlight, drought, or flooding. These studies are summarized in Panel E of Table 1. Of these papers, only the one by Wernerfelt, Slusky, and Zeckhauser (2016) is arguably really about

weather effects per se. The authors find that exposure to sunlight in utero is associated with lower incidence of asthma in affected U.S. cohorts, a result that they attribute to the effect of vitamin D on lung development in utero.

The remaining papers find effects that may work through economic mechanisms as well as through biological pathways. In terms of the Section 1 framework, these papers are implicitly considering the optimized response of h to ΔY (changes in parental income). Given the budget constraint in Section 1, a negative income shock would reduce investments in children in both period 1 and period 2 so as to equate marginal utilities of parental consumption and investing in children (at a higher level). If the marginal utility of consumption increases substantially with reduced consumption, child investments will need to be reduced even more. This may be particularly true at low baseline levels of consumption.

Several studies focus on weather shocks in rural populations where conditions outside the norm may lead to income losses by affecting crop yields; this may be a major pathway through which weather affects child outcomes. For example, Agüero (2014) examine the effect of high temperatures in a nationally representative sample of Mexicans, and find that higher temperatures during early childhood are associated with lower adult height. The effects are greater in poorer districts which could be either because people in those areas are less able to shield themselves through, for example, air conditioning (i.e., a biological effect working through the production function), or because many poorer parts of Mexico are agricultural and heat may cause crop losses (an economic effect working through the budget constraint). One limitation of the work to date is that it is often impossible to distinguish between these pathways.

The remaining papers in Panel E deal with fluctuations in rainfall, which are probably even more likely to lead to crop loss, and thus to affect outcomes primarily through economic channels. The Shah and Steinberg (2016) study is interesting in that it finds that drought has a positive effect on children's educational attainment in India. They explain this finding by arguing that in India, developments that prevent children from working in the fields may benefit their education. In the context of the model sketched above, one would have to add children's potential earnings to the budget constraint and allow weather to affect the market wage for children's labor (and thereby the opportunity cost of schooling investments) in order to capture this effect.

f) Effects of Alcohol and Tobacco on Fetal Development

Finally, Panel F of Table 1 considers three recent papers discussing the effects of alcohol and tobacco control policies on fetal development. While it is well known that alcohol and tobacco can harm the developing fetus, these studies focus on heterogeneity in the effects of policy, and on longer-term effects. Von Hinke, Kessler, and Scholder et al. (2014) find long-term effects of maternal alcohol consumption during pregnancy on children's test scores up to age 16 in data from the Avon Longitudinal Study. This study uses genetic variation in the mother as an instrument for alcohol consumption. Causal interpretation of an alcohol effect requires the assumption that the genetic variation in question has no effect other than through maternal alcohol consumption, which is questionable since currently scientists have relatively little understanding of the multiple pathways through which an observed genetic variation may impact a person. That is, even if we knew with certainty that a particular gene was associated with alcoholism, it might also be independently associated with cognitive problems in the

offspring. An additional concern about the use of genetic data as instrumental variables is that genetic effect sizes are often very small and therefore raise possible concerns about weak instruments.

Using register data from Sweden, Nilsson (2015) investigates the long-term effects of a policy that permitted strong beer sales in grocery stores, which resulted in a temporary and sharp increase in access to alcohol among young people. He finds that cohorts affected *in utero* early in pregnancy had 24% lower earnings at age 30, as well as lower cognitive, non-cognitive, and educational outcomes. Effects were particularly concentrated on males and among children from low-income families. Boys were also more likely to be premature or spontaneously aborted than girls. In terms of equation (1), Nilsson (2015) floats the possibility that boys and girls have different values for ϕ .

Bharadwaj, Johnsen, and Loken (2014) study the effect of smoking bans in Norway. The authors are able to identify mothers who worked in bars and restaurants while pregnant. They find significant effects on health at birth and also on adult income at age 28, but the effect of the reform is much stronger for mothers who were smoking at the start of the pregnancy, suggesting non-linear effects of tobacco exposure.

Simon (2016) examines the effects of changes in state-level tobacco taxes in the U.S. on maternal smoking and child health and finds that higher taxes were associated with fewer days absent from school, and reductions in the utilization of medical care, as well as with 16% fewer asthma attacks. These effects are much greater for the least educated mothers. Barreca and Page (2015) use a similar design to consider state-level changes in minimum legal drinking age laws

and find improvements in birth outcomes among affected cohorts of women. Their estimates are also suggest improvements in the survival of black infants to term.

An economic model of a parent's choice to use alcohol or tobacco while pregnant is complicated by the fact that while in the short-term the parent trades off utility from their own consumption against the investment in a child's health, their actions also directly affect the return to future investment in child health. That is, future investments are likely to be less productive if the child is damaged by fetal alcohol syndrome, for example.

Section 3: Parental Investments

The evidence in Section 2 shows that relatively mild shocks can, if delivered at the right or wrong time, have lasting positive or negative impacts on the developing fetus and young child. The question arises then as to whether there are parental investments that can mitigate the effects of negative shocks. Conceptually, this question centers on the parameters of the CES production function ϕ and γ .¹¹ Knowing that period 1 investments have a large effect on h *per se* tells us relatively little about the effectiveness of period 2 investments, including whether damage from a period 1 shock can be remediated by additional period 2 investments (whereas knowing ϕ and γ would take us closer).

A related question is how parents respond to positive or negative shocks to one of their children: Does I_2^* change in response to μ_{1g} ? Framed this way, the question does not require assumptions about the production technology for h or parental preferences. That said, various underlying concepts from the model will govern any observed investment response. These include parents' preferences (for instance, does the parent wish to equalize outcomes or to

¹¹ Additionally, it depends on the relative sizes of \bar{I}_1 and \bar{I}_2 . See Section 2.1.1 in Almond and Currie (2011b).

maximize the total productivity of their offspring), and the constraints that they face.¹² For instance if a parent cannot afford the cost of intervening to help a disabled child, but can afford basic investment in a non-disabled sibling, then their choice may well be obvious. If many parents are constrained in their investments, then social investments may have an important impact on parent's choices by changing the productivity and cost of their own investments. Thus, distinguishing between behavior due to preferences and behavior due to constraints can be a key input to intelligent policy responses. Moreover, as Heckman (2008) points out, it may be the case that timing matters. The productivity of current investments may depend in important ways on whether past investments have taken place.

Table 2 summarizes some of the recent literature on parental investments. Hsin (2012) was one of the first papers to consider that parental investments in their young children may reflect not only preferences, but also constraints. Using sibling fixed effects models and employing data from the Panel Study of Income Dynamics (PSID), she showed that college educated mothers compensate low birth weight children (i.e., invest in order to try to equalize outcomes) while less educated mothers tended to concentrate resources (such as reading, playing, and doing hobbies) on higher birth weight children. A limitation of her study is that the number of low birth weight children with low birth weight siblings is quite small in the PSID so the results are suggestive rather than definitive about the behavior of U.S. parents.

Breining et al. (2015) find evidence consistent with parents trying to equalize outcomes between siblings. They use Danish registry data and examine children whose siblings were either

¹² The returns to investment are governed by the elasticity of substitution of investment made at different stages of childhood. These returns have an impact on whether parents compensate versus reinforce, whatever their preferences are. For example, if a parent wants to compensate, but there are no suitable investments available or their return is low, then he or she will might well choose to invest in another child which would have the effect of reinforcing differences.

just above the 1500 gram threshold used to classify children as very low birth weight or just below it. Children just below the threshold were found to receive more care and be healthier subsequently (as in Almond, Doyle, Kowalski, and Williams, 2010). The novel finding is that their siblings also do better in school, which suggests that medical intervention for the very low birth weight child benefitted all the children in the family. One interpretation of this result is that parents would otherwise have sacrificed the well-being of the healthy children in order to focus on the more vulnerable child. Alternatively, however, shocks to one child may work through the budget constraint to affect other children even in a rich country like Denmark where most medical care would be paid for by the state.

Akee et al. (2015) investigate the effects of a casino opening on the Eastern Cherokee reservation which resulted in an exogenous income transfer to tribal households. They find that parents reacted to the transfer by investing more in children who had lower levels of mental health and “worse” personality traits. This result seems to reflect preferences for equal outcomes—although the mechanism is a change in the budget constraint, the parent has a choice about which child to spend the “extra” money on. On the other hand, several studies in developing countries (Yi et al., 2014; Adhvaryu and Nyshadham, 2016) find evidence consistent with parents reinforcing initial differences between children which could reflect either preferences, ϕ , or budgetary realities.

Two studies of gender differences in investments also find opposite results for developing and developed countries. Bharadwaj and Lakdawala (2013) focus on India, China, and Bangladesh and find that mothers pregnant with a boy get more prenatal care and that boys are more likely to receive tetanus shots after birth. One only sees the difference in prenatal care

among mothers who had an ultrasound and so presumably know that they are carrying boys. However, in Canada, the U.S., and the U.K., Baker and Milligan (2016) find that parents of children aged 0 to 3 put more time into girls and that this time investment can explain as much as a third of the gender gap in reading scores in the early grades. It is possible that this pattern reflects mother's preferences for girls if mothers are the primary caregivers.

From this brief description of a number of studies, it should be apparent that there is no simple answer to the question of whether or why parents compensate or reinforce differences between their children.¹³ It does seem that parents are more likely to reinforce differences in low resource settings, suggesting that the observed behaviors are at least partially a response to binding budget constraints in many instances.

The discussion above assumes that parents are making informed choices about investments in their children. Dizon-Ross (2015) investigates how parental investments responded to better information about children's academic performance using a field experiment in Malawi that targeted parents with young children. Results show that providing parents with information about how each child is doing causes them to reallocate their educational investments across children so that investments correspond more closely to their children's true achievement level.

¹³Fryer, Levitt, and List (2015) focus on a different but related question, which is whether we can incentivize parents to invest more in their young children? They organized a randomized trial in Chicago in which parents were rewarded for activities such as attending educational sessions about early childhood, completing homework assignments with their children, and for their child's demonstration of mastery on interim assessments. These tasks were chosen to improve cognition and executive function. They found that the intervention benefited white and Hispanic children, but not African-American children. Moreover, effects were bigger for children with better cognitive skills to begin with. This study may illustrate some of the limits of trying to improve children's outcomes by working to improve parenting skills.

Similarly, Cunha, Elo, and Culhane (2015) argue that U.S. mothers have poor information on the return to early childhood investments. They speculate that if the government could implement a policy that moved expectations from the median current belief to the true median return, that parental investments would go up by 4% to 24% and the stocks of cognitive skills at age 24 months would increase by 1% to 5%. If parents lack information about the likely impact of investments in their children, then once again their behavior cannot be said to reflect their underlying preferences; perhaps information could be modeled as an input into child health production such that parents with incorrect information end up optimizing with respect to the wrong production function.

Perhaps an overall take away is that economists have been too quick to interpret parent's choices as revealed preference when even a simple economic model suggests that factors such as available production technologies and budgets, not to mention information, are likely to be tremendously important.

Section 4: Sometimes Lightning Strikes Twice

In this Section (and in Table 3) we consider a handful of studies that attempt to examine dynamic complementarities empirically using cases where there were two shocks. These studies are often reminiscent of the first generation of fetal origin studies in their reliance on quirky and exotic instruments (which is why we characterize them as akin to being struck twice by lightning), and in the fact that it may be difficult to generalize some of their conclusions to other settings. Nevertheless, they represent the frontier in terms of trying to apply insights from the theory outlined in Section 1 to applied work in this area.

Aguilar and Vicarelli (2015) overlay variation from Mexico's conditional cash-transfer Progresa program on top of rainfall shocks induced by El Niño. They consider shocks that affected children both prenatally and up to age 2 and examine anthropometric and cognitive outcomes at ages 2 to 6. They did not find that Progresa mitigated any of the negative effects of weather shocks. In contrast, Adhvaryu et al. (2015) use a very similar design and ask whether Progresa mitigated the effects of rainfall shocks on cognitive test scores and years of education measured at ages 12 to 21. They estimate that Progresa offset 60 to 80% of the negative effects of rainfall shocks on child development. It is unclear whether these conflicting results are caused by subtle differences in the approaches taken, or whether it is really the case that one can see positive long-term effects even in cases where the immediate short-term effects appear to be negligible. Certainly much of the literature on early intervention programs has this flavor, finding initial effects that “fade out” by age 8 or 9 but then reappear in adulthood (Almond and Currie, 2011b).

Gunnsteinsson et al. (2016) examine data from a randomized controlled trial of Vitamin A supplementation in Bangladesh that took place between 2001 and 2007. In 2005, parts of the study area were devastated by a tornado. The authors find that tornado exposure in early pregnancy and early infancy had significant negative effects on birth weight and infant anthropometrics. However, they also find that infants treated with vitamin A at birth were effectively protected from the effects of experiencing a tornado shock at 0 to 3 months of age in that there did not appear to be any effect of the tornado on anthropometrics at 6 months. An unusual feature of this paper is the author's care in trying to entangle the optimal timing of the protective investment relative to the timing of the shock.

One difference between Gunnesteinson et al. and Advharyu et al., is the amount of time that occurs between the negative shock and the human capital investment. While in the case of the tornado in Bangladesh the interval between the shock and the vitamin A supplementation was only a few months, and the outcome was measured a few months after that, in the Progres paper, the interval between the transfer and the weather shock was at least a decade. The temporal gap between the first and the second event may be relevant to identifying these interactions, as there may be behavioral responses from parents or teachers that could either reinforce or undo the impacts of the first or the second event, or both.

Rossin-Slater and Wust (2015) consider a somewhat different, but related and very important question of how different types of common public early interventions interact. They use Danish registry data to study the interaction of a nurse home visiting program that supplies visits shortly after birth, and a childcare program for three-year-old children. Both programs rolled out beginning in the 1930s and ending in the 1950s. They find that the childcare program had large and persistent effects on educational attainment and income, and reduced adult mortality. In an innovative twist, they also find that the benefits extended inter-generationally to the children of the originally treated children.

A surprising finding however given the dynamic complementarities hypothesis, is that the effects of child care programs were largest for children who had not had exposure to the nurse home visiting program as newborns. At first blush this finding seems the opposite of the “skills beget skills” concept that children who got off to a good start due to the home visitors would be better able to benefit from the child care program. A possible explanation is that the programs actually provide similar but complementary services. For instance, home visiting often focuses

on training parents about health and safety, as well as teaching them what they can expect developmentally from children of various ages. To the extent that a successful program trained parents to give better care at home, that might lessen the benefit of having better care in another setting. We are not aware of other studies of this type, so it is impossible to know how much the complementarities depend on the type of intervention, though it is reasonable to suppose that they would. Regardless, this handful of early two-shock studies establishes that estimating dynamic complementarities in a well-identified way is feasible with enough creativity and luck.

Section 5: How Do Resources Mediate the Effect of Early Life Events?

Broadly considered, there are two types of resources that can be expected to benefit children: Material resources (Y) and time inputs (I_t), which might be an argument in the production of child investments. In addition, parents of higher “quality” may be expected to make better use, on average, of the resources at their disposal (indeed, perhaps this should be considered as part of a definition of parent quality along with evidence of altruistic preferences towards the child). In equation (1), the productivity parameter A might be indexed by parental type, with $A^H > A^L$, where H represents “high” quality and L represents “low” quality. At the same levels of income, type “H” parents could achieve better child outcomes (and higher consumption) than type “L” parents. As we discussed above, one might think of higher quality parents as having access to a different production function than other parents. Accordingly, in this section we focus on policies that affect parental education as well as income and in-kind support and parental leave policy.

a) Effects of Material Resources

Many recent papers examine the effects of cash transfers on child outcomes in a range of settings. We can think of these policies as exogenously increasing Y , which according to (3), would increase both childhood investments and consumption. Aizer et al. (2016) assemble unique historical administrative data about the U.S. mother's Pension Program (a precursor to modern welfare programs). They ask whether being accepted into the program affected outcomes observable on WWII enlistment records or mortality risk (measured using age of death on death certificates). They find that being accepted increased longevity by 1.5 years on average, with larger effects in the poorest families.

Two papers, by Hoynes, Miller, and Simon (2015) and Dahl and Lochner (2012) examine the effect of the U.S. Earned Income Tax Credit Program (EITC). Although it is administered through the tax system, these refundable tax credits function rather like a Conditional Cash Transfer program in that they are mainly available to families who work and file a tax return, that is, they are conditional on working. Both papers exploit variation stemming from a significant increase in the generosity of the program in the mid-90s. The first study finds reductions in the incidence of low birth weight among mothers who benefited from the expansion while pregnant, while the second finds increases in a range of cognitive test scores, which are larger for children from the most disadvantaged families. One possible mechanism contributing to these effects is the positive link between EITC and mother's health (Evans and Garthwaite, 2014).

Black et al. (2014) and Milligan and Stabile (2011) consider cash transfers that are targeted to children (a child care subsidy and a child allowance, respectively). Like Dahl and Lochner, both also find significant improvements in a range of cognitive test scores. Milligan and Stabile find that these effects are mainly driven by boys.

Set against these generally positive findings is the paper by Del Boca, Flinn, and Wiswall (2014) which estimates a structural model based on observational data from a variety of data sets. Their estimates suggest that monetary transfers will likely have only small effects on children because most of the transfer is likely to be spent on other types of consumption, or on parental leisure. However, they are not measuring the effects of an actual transfer policy using design-based variation in that policy.

A second group of papers looks “near cash” programs supplying food aid. It is often argued that if the amount of an in-kind transfer is small relative to the household’s budget for that item, then in-kind transfers will have much the same impact as cash. The studies of the U.S. Food Stamp program (now known as SNAP, the Supplemental Nutrition Assistance Program) by Almond, Hoynes, and Schazzenbach (2011) and Hoynes, Schazzenbach, and Almond (2016) find (respectively) that the roll out of the program increased birth weights, especially among African Americans, and that in the long-term the roll out reduced the incidence of metabolic syndrome (i.e., obesity, high blood pressure, diabetes, etc.) which in turn increased the economic self-sufficiency.

Rossin-Slater (2013) examines the opposite type of policy, which is closures of clinics providing WIC (Supplemental Nutrition for Women, Infants, and Children) in Texas in the late 2000s. WIC closures reduced WIC participation, reduced the probability that a mother gained an adequate amount of weight during pregnancy, and reduced birth weight. Similarly, Meckel (2015) finds that crackdowns on WIC fraud caused small retailers to exit the program and reduced mother’s prenatal participation in WIC with negative effects on birth outcomes.

A number of studies look at the broader effects of economic circumstances on child outcomes. Arguably, good economic times may have effects not only through increasing family resources but also through increasing employment (with either positive or negative effects for children depending on the range of child care options available) and social resources. For example, more money may flow to schools and social services in good times. Hence, studies of the effects of business cycles may not tell us about precise mechanisms, though they do once again suggest the vulnerability of young children. The studies by Loken, Mogstad, and Wiswall (2012) and Adhvaryu et al. (2016) examine the oil boom in Norway and a cocoa price boom in Ghana, respectively. These find positive effects of good times with the impacts being felt disproportionately in low-income households.

Lindo (2011) and Carlson (2015) examine the effects of job displacement during pregnancy on health at birth outcomes. Lindo focuses on the father's job loss using data from the Panel Study of Income Dynamics and controlling for mother fixed-effects. Carlson uses data from notices filed under the Worker Adjustment and Retraining Notification Act aggregated at the county-month data to examine the effect of anticipated job losses. Both studies find negative effects on birth weight. Golberstein et al. (2016) go beyond examining effects on health at birth and examine children's mental health. The paper finds that a one standard deviation increase in the state unemployment rate has a negative impact on child's mental health (assessed using the Child Strength and Difficulties Questionnaire) and is associated with a 5.7% increase in the use of special education services for emotional problems. Given the nature of the shock examined (i.e., the Great Recession) and the magnitude of the effects on clinically meaningful outcomes, it would be interesting to know whether these impacts will persist over time.

Bharadwaj, Lundborg, and Rooth (2014) ask how low birth weight affects vulnerability to economic shocks later in life using Swedish administrative data and models with twin fixed effects. Their estimates suggest that a 10% increase in birth weight results in a one percent decline in the probability of using unemployment insurance during a recession as an adult. Conversely, using Dutch data, Scholte et al. (2015) find that individuals subjected to economic downturns early in life are more likely to have chronic diseases and functional limitations in old age.

Two studies by Gould, Lavy, and Paserman (2011) and Lavy, Schlosser, and Shany (2016) study the children of Ethiopian Jews who were air-lifted to Israel either as young children, or while in utero. Those children air-lifted to Israel experienced large differences in material conditions depending on where their families were assigned, and families had little say in this decision. Children who had running water, sanitation, and electricity in early childhood obtained more education, were more likely to be employed, and were less likely to have health problems in later life. Children air-lifted while in utero, faced different conditions during their mother's pregnancy compared to children air-lifted shortly after birth. Those children who experienced Israel's better conditions prior to 8 weeks of gestation did better on standardized tests and obtained more education. Perhaps curiously, these studies both find that the effects were concentrated mainly among girls. They attribute this finding to gender discrimination, particularly in Ethiopia and in the more backward parts of Israel. The idea is that parents would have been more likely to stint girls, so girls are particularly benefitted by relaxation of resource constraints. If this explanation is correct, then the result highlights the fact that the effects of a shock reflect both "biological" effects and the influence of social conditions, and that it is difficult to disentangle the two.

Rossin-Slater (2016) highlights a very different type of policy which also had the capacity to change many aspects of a child's living situation: Changes in U.S. laws governing paternity establishment. Many states adopted policies aimed at making it easier to establish paternity in the hospital. A goal of these changes was to encourage parents to marry. Since married families are generally better off than single-parent households, such a policy might be expected to increase the resources available to children (both in terms of income and possibly father's time). However, Rossin-Slater argues that any positive effect on marriage rates was offset by the fact that the law also made it easier for some mothers to gain child-support without marrying the father. Overall, she finds little effect on measures of paternal involvement or child health, but some negative effect on children's health insurance coverage and utilization of medical care, which may be a result of losing access to paternal employer-sponsored health insurance coverage. This is one of very few studies to explicitly consider the role of fathers in providing resources to households, something that it would be useful to see more of.

Chetty, Hendren, and Katz (2016) focus on the Moving-to-Opportunity (MTO) experiment that randomly offered families living in housing projects vouchers that enabled them to move. Combining MTO experimental data with administrative data from federal tax returns, the authors find significant differences in the later-life outcomes of children who moved when they were less than 13 years old. Moving to a lower-poverty neighborhood improved college attendance rates by 15% and earnings by 14%. Treated children were also 4% more likely to live in better neighborhoods as adults and 15% less likely to become single parents. In contrast, children who moved later in their adolescence either did not benefit or actually faced negative long-term impacts. One potential explanation for these differential effects is that moving to a very different environment as an adolescent could disrupt social networks and have other adverse

effects on child development. The authors discuss potential intergenerational gains to providing access to better neighborhoods to families in public housing, which ultimately could generate positive of these policies returns for taxpayers.

b) Policies to Promote Maternity Leave

If childhood investments are an increasing function of parental time, then maternity leave policies may increase investments at key developmental stages. Such policies appear to be predicated on the belief that the elasticity of child investments in (1) with respect to parental time is large in very early childhood. The key policy question is when specifically maternal (or paternal) time is most important? Recent studies focusing on the effects of maternity leave policy on child outcomes are summarized in Panel B of Table 4. At first glance it is difficult to see any consistent picture in these estimates. However, on closer examination, a story emerges in which facilitating short maternity leaves is highly beneficial, but extended maternity leaves do not have a positive effect. This pattern seems plausible if child investments are an increasing but concave function of maternal time or if the return to childhood investments is diminishing in the investment level.

Rossin-Slater (2011) studies the implementation of the Family and Medical Leave Act in the U.S., a federal law allowing women to take up to 12 weeks of unpaid maternity leave. The law superseded a patchwork of state laws, creating a good deal of variation which she exploits. She finds a positive effect on the birth outcomes of college educated women. These women are more likely than less educated women to have been able to afford to take unpaid leave. Similarly, Carneiro, Loken, and Salvanes (2015) study the effect of a 1977 Norwegian law which replaced a legal right to 12 weeks of unpaid leave with four months of paid leave and an additional right

to take 12 months of unpaid leave. They find that children of affected mothers got more education and had higher wages at age 30. Thus it appears that allowing some maternity leave in the first months of life was associated with better outcomes in these two examples.

In contrast, Baker and Milligan (2015), Danzer and Lavy (2016), and Dahl et al. (2016) study expansions of paid leave from 25 weeks to 50 weeks, 12 months to 24 months, and 18 weeks to 35 weeks, respectively. Baker and Milligan (2015) actually find some evidence of negative effects on children's test scores among boys and among children of more educated mothers. Dahl et al. (2016) find no effects on adult outcomes. Danzer and Lavy (2016) do not find any overall effect, but report that there was some benefit to the reform for children of more highly educated mothers, but negative effects among children of less educated mothers. Thus, although there is some disagreement about the magnitude and direction of effects, there is little evidence in any of these studies that long maternal leaves have overall benefits for children. One possible interpretation is that mothers who go back to work after the first six months manage, on average, to find child care that approximates the care they would offer in their own homes.

c) Policies to Promote Child Care

Panel C of Table 4 reviews recent work on the feasibility of investing in young children through organized child care. These studies are organized into three categories: Long-term follow-ups of small-scale demonstration programs; long-term follow-ups of large, publicly funded programs; and short-term results of more recent demonstration programs.

There is a good deal of previous work showing long-term effects of small-scale child care demonstration programs conducted using randomized controlled trials including Perry Preschool and the Carolina Abecedarian Program. We have reviewed these programs extensively

elsewhere.¹⁴ Suffice it to say here, these studies involved interventions of medium and strong intensity (respectively) with groups of very disadvantaged preschool children. At the time these demonstrations took place the alternative was generally no preschool, rather than some other type of preschool, which is the default today.

Studies by Heckman, Pinto and Savelyev (2013), Campbell et al. (2014), and Conti, Heckman, and Pinto (2015) add to this literature by showing that the interventions had positive effects on a broader set of outcomes than had previously been considered. In particular, they find positive effects on personality traits, health behaviors, and health outcomes. All of these measures have been shown to have important impacts on employment and earnings, though the focus in evaluations of early childhood interventions is often solely on test scores. These studies also take care to correct their estimates for complexities such as attrition and imperfect random assignment, as well as for multiple hypothesis testing (i.e., the problem that if you test 20 hypotheses, it is likely that one of them will fail to be rejected with 95% confidence even if there are in fact no underlying causal relationships). It is increasingly well understood that it can be difficult to interpret results from some randomized experiments given these sorts of problems.

A second set of studies extend the large literature on the effects of public preschool programs in various ways. Havnes and Mogstad (2015) examine the effect of a Norwegian reform that extended publicly funded preschools. The availability of preschool varied across space and time, and the authors exploit this variation to identify its effects. A striking finding is that the reform increased the eventual adult earnings of affected children in the poorest households, but *reduced* the earnings of affected children in the richest households. The paper is

¹⁴ For instance, Almond and Currie (2011b) review some of the studies evaluating these programs in Table 11, p. 1435.

therefore a very nice demonstration of the fact that childcare centers do not exist in a vacuum—hours in child care replace some other form of care for the child. If the care that is replaced is worse than the child care center, then one can expect improvements in child outcomes and vice versa. Of course income matters too. To the extent that child care allows women to work and earn more, their higher earnings may also benefit their children and could possibly offset a mild negative direct effect of child care. One would expect the marginal value of additional earnings to be higher in lower income households, even though more educated women are likely to earn more per hour.

A recent study by Baker, Gruber, and Milligan (2015) showed that the introduction of a universal child care program in Quebec led to negative effects on children's non-cognitive outcomes (with little gain in cognitive test scores), significant declines in long term self-reported health and life-satisfaction, and behavioral problems and criminal activity among boys. These results are quite consistent with those of Havnes and Mogstad because the modal child who was brought into child care as a result of the reform was a middle class child who went into a low-quality, hurriedly-created, child care facility.

Aizer and Cunha (2014), Gelber and Isen (2013), and Kline and Walters (2016) examine the U.S. Head Start program, a publicly funded program that originally served 3 to 5 year old children, but has increasingly served younger children as well. Aizer and Cunha (2014) focus on the roll out of Head Start in the mid-1960s using data from the National Collaborative Perinatal Project and find that children who were able to participate in Head Start had test scores that were 0.1 to 0.2 standard deviations higher at age 7 than those of their older siblings. However, like the parenting intervention studied by Fryer, Levitt, and List (2015), the effect was greatest for the

children with the highest initial endowments. Aizer and Cunha also examine the compensation vs. reinforcement question, and find that in this low-resource setting, parents invested more in highly-endowed children and that parental investments complemented investments from Head Start. Gelber and Isen (2013) focus on parenting practices in Head Start cohorts from the early 2000s who were followed as part of the Head Start Impact Study, a randomized controlled trial intended to examine the short-run impacts of Head Start. They also find that Head Start enrollment tended to increase parental investments.

Kline and Walters (2016) offer a re-examination of data from the Head Start Impact Study. Original analyses found that Head Start had some positive effects on children in the short run, but that these effects quickly “faded out.” Kline and Walters point out that about a third of the children treated in the Head Start Impact Study were drawn from other publicly-funded preschool programs and that many of the controls attended other public preschools. One would not necessarily expect to see any difference between Head Start children and children in other similar public preschool programs. Ignoring this fact substantially overstates the cost of providing Head Start to the study children (since a third of them would have been receiving preschool at public expense anyway), and also understates the positive effects of attending a public preschool of some sort; Hence naive estimates substantially underestimate the cost-effectiveness of the program. Using estimates from previous work showing that short-term boosts in test scores are associated with long-term gains in outcomes (e.g., Garces et al, 2002; Chetty et al, 2011), they estimate that Head Start is likely to be a cost effective program. Interestingly, the eligible children who were not participating in the early 2000s were those with the highest potential benefits, suggesting that expansions that drew these children into care could be even more cost effective.

A common theme in these studies of public preschool programs in developed country settings is that a failure to consider the available alternatives to child care programs leads analysts to understate the positive social returns to expanding these programs.

A third group of recent studies (all randomized controlled trials) examine preschool programs in developing countries. The two papers by Attanasio and collaborators examine the effects of a home based psychosocial intervention program and a center-based preschool program that was implemented in poor Colombian towns. Both interventions find positive effects, though on different domains (cognitive test scores and height-for-age, respectively). Perhaps the main take away is that such publicly funded, large-scale programs can have positive effects even in very low resource settings. Gertler, Heckman, and Pinto et al. (2014) examine the long-term effects of an intervention to provide psychosocial stimulation to impoverished Jamaican children. An ambitious aspect of this project is that they attempted to track migrants, pointing out that in Jamaica, many successful people emigrate and are lost to follow up unless special care is taken to retain them in the study. This study finds large effects of the psychosocial intervention on adult earnings.

Taken as a whole, the studies summarized in Panel C of Table 4 add to the extensive literature on the potential for early intervention programs to improve children's short and long-run outcomes. Both high quality center-based programs and home visiting interventions appear to be effective and have the potential to influence many domains, including education, income, employment, health, and future health behaviors (see Almond and Currie, 2011b for a review of work on this topic before 2011).

d) Policies to Promote Medical Care

Much of the literature on the long-term effects of medical care in childhood exploits the revolutionary expansions of public health insurance (Medicaid) coverage to children in poor and near poor families that occurred in the U.S. during the 1980s and 1990s. But other rich countries have also made efforts to improve medical care for young children, and some of these investments have also been evaluated. Recent studies of the issue are reviewed in Panel D of Table 4.

One noteworthy study by Sievertsen and Wust (2015) uses rich administrative registry data from Denmark and exploits county-by-county variation policies mandating same-day post-birth discharge. Same-day discharge following normal deliveries was apparently implemented as a cost saving measure in a staggered way across Danish counties. They find that same-day discharge leads to a 75% increase in readmissions during the first month of life and also increases contacts with general practitioners. The largest effects are found for disadvantaged mothers (defined in terms of age, education, and income). The authors are able to link administrative data sets together in order to examine long-term effects of this policy change on 9th grade test scores. They find that the policy was associated with a .2 standard deviation decline in test scores in children born to disadvantaged mothers. While modest, this effect is in line with the effect sizes seen in many educational interventions and highlights the inter-relationship of health and cognitive achievement.

Bharadwaj, Loken, and Neilson (2013) examine infants in Chile and Norway and exploit the fact that infants below the 1500g threshold cutoff used to define very low birth weight received more intensive medical services than those just above this threshold. In addition to

finding significant effects on infant mortality in each country, they also find that more intensive medical care increased adult wages by 2.7% in Chile and by 1.8% in Norway.

Studies of the U.S. Medicaid expansions use a variety of methodologies and data sets, but generally rely on the fact that the Medicaid expansions were phased in at different rates across the states (although the expansions eventually became mandatory in every state). Brown, Kowalski, and Lurie (2015) use U.S. Internal Revenue data from tax returns which allows them to examine income and payroll taxes as well as college attendance as outcomes. Cohodes et al. (2016) use publicly available data from the Census, the Current Population Survey, and the Youth Risk Behavior Surveillance System to examine effects on educational attainment. Meyer and Wherry (2016) and Miller and Wherry (2014) examine effects on mortality using Vital Statistics data and on obesity, body mass index, and hospitalizations for endocrine disorders using data from the NHIS, while Wherry et al. (2015) look at hospitalizations and Emergency Room visits using hospital discharge data.

All of these studies find positive long-term effects of having been eligible for health insurance coverage in childhood, suggesting that improved access to medical care in childhood increases the health and productivity of adults. These findings are significant as Medicaid is possibly the largest U.S. policy engaging “fetal origins” linkages, and represents one of the largest social investments that has been made in U.S. children. There is some heterogeneity in the estimated long-term effects. The effects are strongest for African Americans (who were most strongly affected by the expansions, given their lower average incomes and resulting higher eligibility for public insurance). Brown et al. do not see race in the tax data, but find stronger effects on earnings among women than among men. The take away from these studies is that

even in rich countries where much of the morbidity is due to behavioral factors rather than infectious disease, improvements in access to medical care matter for long-term outcomes, especially among the disadvantaged.

e) Maternal Education

In Grossman (1972), more educated individuals are more efficient producers of health. Analogously here, it may be the case that better educated parents have $A=A^H > A^L$, which would yield higher child outcomes h , other things equal. As Currie and Moretti (2003) point out, maternal education is endogenously chosen, and has possible effects on many aspects of a woman's life,¹⁵ including fertility choices. McCrary and Royer (2011) and Carneiro, Meghir, and Paredy (2012) examine the effect of policies that affected the amount of maternal education. The first paper exploits discontinuities created by rules about age-at-school entry. The idea is that children who are slightly too young to enter school must wait a year and will be in lower grades when they reach the age at which they can legally leave school causing the marginal children to end up with less education than children who were just above the age cutoff for school entry. McCrary and Royer find little overall effect of additional compulsory education on either fertility or infant health, though for African-American women, they do find some reduction in the incidence of low birth weight.

This result contrasts with Currie and Moretti, who examined the effect of additional years of college education induced by having a college open in the mother's county when she was 17 years old. These openings were associated with large improvements in infant health, possibly

¹⁵ There is no time budget in our stylized model. Were labor income a function of hours worked, then another margin for optimization would presumably be through the shadow price of parental time spent on investing in children. Increases in education could increase the return to work and shadow price of time spent investing in children, with ambiguous predictions on net investments given competing income and substitution effects.

through the mechanism of reducing maternal smoking. McCrary and Royer study a different margin (years of high school) and find no effect on smoking, so a possible explanation for these conflicting results is that the studies are looking at different margins presumably affecting different parts of the distribution of potential mothers. Carneiro et al. (2012) also focus on college education and instrument for education using variables such as tuition and distance to college. They find positive effects on child test scores, with slightly larger effects for African Americans.

In order to place these results in context, it is important to note that the fraction of U.S. women with less than a high school degree has fallen by more than 50% in the last 25 years, and there is increasing evidence that high school dropouts and those with only a high school degree fare similarly in the labor market (Card, 2009). Hence, college may be the key margin for maternal education to affect child health in the United States.

Section 6: The Missing Middle and Latent Effects

In order to examine the long-term impact of policies experienced as young children, researchers must wait patiently to observe a “fully formed” measure of h . For example, Hoynes et al. (2016), Dahl et al. (2016), and Isen, Rossin-Slater, and Walker (2016) study the impact of policies that were rolled out 30 to 40 years ago. In addition to the usual difficulties identifying policy effects, these studies must address the problems involved in tracking affected people or cohorts over decades. In the case of Hoynes et al. (2016) the problem was addressed by gaining restricted-access information on county of residence over time in the Panel Study of Income Dynamics, while the other two studies rely on administrative records that geocode county of birth.

Clearly, while long-term follow up is the most reliable way to assess whether a policy is effective in the long-term, it limits our ability to assess *current* or even recent policies within a reasonable amount of time. While economists may be particularly interested in adult productivity and earnings, skipping the middle years between early childhood and adulthood means that we have little idea about what typical developmental trajectories look like and how they are shaped by policies experienced over the life course. If we knew more about the relationship between early childhood, middle-childhood, and adulthood, it would aid us in making medium-term inferences about those early childhood policies that are likely to successfully impact adults. Our lack of knowledge also means that we are largely shooting in the dark when trying to compare the efficacy of programs targeted at very young children to those targeting older children. While there is a wide-spread perception that it is more cost-effective to focus on the very young, there is surprisingly little direct comparison of policies targeting different age groups.

An additional reason to be interested in the middle years, is that the limited amount that we do know presents some real puzzles. For instance, a common finding in the literature evaluating early childhood intervention programs is that there is an immediate gain in test scores, followed by “fade out” of test score gains in the early elementary school years (Almond and Currie, 2011b; Currie and Thomas, 1995). However, these same children tracked many years later often show positive effects of the intervention in terms of completed schooling attainment and other measures (Garces et al, 2002). Are the initial test score effects a “red herring” in that the intervention is really affecting something else that matters for future development (such as non-cognitive skills)? Or do the initial effects on cognition simply become latent for some period of time and re-emerge?

In many cases, data on the “missing middle” is simply unavailable. For instance, Isen, Rossin-Slater, and Walker know where people were born, and link information about their birth counties to their adult earnings records. Their data has no information on movement patterns between birth and adulthood, which is perhaps something that could be examined using tax records, as in Chetty et al. (2016). However, a few recent papers have begun to examine the effects of events in early childhood on outcomes during the school years.

A few of these papers have already been discussed. For example, in student register data for Pakistani and Bangladeshi families in England, Almond et al. (2015) examined whether Ramadan's overlap with pregnancy affects subsequent academic outcomes at age 7. They find that test scores are 0.05 to 0.08 standard deviations lower for students exposed to Ramadan in early pregnancy.

A few additional studies focusing on middle childhood are summarized in Table 5. Figlio et al. (2014) use the universe of births in Florida matched to data from standardized tests. They find that in models with twin fixed effects, increases in birth weight are associated with higher performance. The estimates are slightly smaller than those found in Black, Devereux, and Salvanes (2007) who conducted a similar investigation in Norway. Bharadwaj, Eberhard, and Neilson (2013) report very similar findings for Chile. A further interesting result is that the effects of low birth weight are largely stable between the ages of 9 and 14 in Florida, and between 1st and 12th grade in Chile.

Another approach to the problem of measuring trajectories is to try to develop better measures of fetal damage, i.e., quantifying μ_{1g} and μ_{2g} . We know for example, that low birth weight is an extremely crude measure of fetal damage, which while predictive, is certainly not

dispositive. There are babies who were low birth weight who seem to be just fine ex-post, and many babies who are not low birth weight but who nonetheless have developmental problems. Robinson (2012) attempts to distinguish between “brain sparing” forms of low birth weight, and low birth weight that is associated with evidence of brain damage. He does this largely by focusing on head circumference, which may feel uncomfortably close to the preoccupations of early eugenicists. His estimates suggest that there are no cognitive effects of low birth weight in the infants with brain sparing. However, his low birth weight infants were more likely than normal weight siblings to have congenital malformations, and vision, hearing, or speech abnormalities regardless of head circumference. Biomedicine has proposed some intriguing alternative metrics to birth weight, e.g., telomere length, methylation patterns, etc., but none that have gained widespread acceptance as yet.

The multidimensional nature of both investments (I) and outcomes (h) (Heckman, 2007) is one reason for the measurement problem. It is unclear whether any unidimensional metric will ever fully capture the effects of early childhood policies and investments insofar as they will impact later life outcomes. At present, waiting until cohorts reach adulthood to observe effects remains useful, though it is severely limiting. For example, how do we know today whether policy A or B will have bigger long-term effects? Presumably this is where a structural, well-calibrated model of investments in early childhood and human capital formation could help to fill the gaps in our knowledge. In addition, a potential avenue of research could be the development

of “sufficient statistics” to identify key reduced-form elasticities that summarize the human capital effects of early life shocks or investments.^{16, 17}

Section 7: Discussion and Conclusions

We now know that variegated shocks, some of them relatively mild and brief, can have lasting measurable impacts on child outcomes. Many authors start from the basic, scientific perspective of asking whether shock X has a casual effect on outcome Y . While that is an important question, it is reasonable to ask whether, given all of this research, we can say anything yet about the relative magnitudes of the effects and in particular, about which investments and interventions would be most cost effective in terms of improving young children’s future outcomes? Answering this question is hampered by the wide range of both shocks and outcomes that have been considered. However, at this point a large number of studies have examined three types of outcomes: Birth weight (and low birth weight), test scores, and wages -- three outcomes that offer glimpses of an individual’s well-being at birth, in childhood, and in adulthood.

Table 6 summarizes what some of these studies have found. These estimates do not lend themselves to comparative analysis of cost-effectiveness. For one thing, we do not have estimates of what it would cost to prevent or ameliorate some types of shocks such as stress due to a death in the family or domestic violence. Still, given what we know about interventions that

¹⁶ Bleakley (2010), for instance, showed that years of schooling is not a sufficient statistic for measuring the impact of early-life health on lifetime income as it is possible that when health improves, lifetime income goes up, but years of schooling declines.

¹⁷ The use of sufficient statistics has been relatively common in other fields of economics such as in public finance, for welfare analysis. For instance, Chetty (2009) showed that in order to calculate the welfare impact of a tax policy, one only needs to estimate the elasticity of equilibrium quantity with respect to the tax rate and avoid estimating all the “primitive” parameters in a structural model.

are feasible and a rough idea about the likely costs of intervention, the table can serve as a starting point for a discussion about what interventions appear to be most promising.

Studies that focus on birth weight as an outcome are shown in Panel A. Unfortunately, we don't know whether small changes in birth weight for babies well above the cutoff for low birth weight will have meaningful effects on future adult outcomes. Studies that focus on effects on mean birth weight can answer the rudimentary question of whether a given shock affects the fetus, but are not necessarily well suited to considering the cost effectiveness of intervention because we don't know how much a small change in the entire distribution of birth weight is likely to be worth.

On the other hand, we do know that low birth weight is associated in a meaningful way with future outcomes such as adult health, schooling attainment, and wages (see for example, Bharadwaj, Lundborg, and Rooth, 2014; Bharadwaj, Eberhard, and Neilson, 2013; Figlio, Guryan, Karbownik, and Roth, 2014). Table 6 suggests that there is low hanging fruit in terms of potential for meaningful interventions to reduce the incidence of low birth weight. For example, Schwandt (2016) finds that reducing severe influenza cases among pregnant women would have a meaningful effect on the incidence of low birth weight (and on children's future wages). This goal could be accomplished quite cheaply by promoting immunization for influenza among women of child bearing age.

Hoynes, Miller, and Simon (2015), Almond, Hoynes, and Schazzenbach (2011), and Rossin-Slater (2013) find that small increases in annual income (or equivalent in-kind transfers) have relatively large impacts on the incidence of low birth weight, which suggests that some sort of pregnancy bonus or mother's allowance might have positive effects at a modest cost

(compositional effects aside). Another policy which could accomplish the same thing though perhaps at higher cost is paid maternity leave, which would be particularly valuable if it covered some of the prenatal period (Rossin-Slater, 2011).

Conversely, uncertainty about income seems to be extremely harmful (Carlson, 2015). It isn't clear at this point how much this problem could be mitigated by expanding unemployment insurance, or at what cost. For example, we don't know how many pregnant women or their partners now qualify for unemployment insurance (UI) or how much they typically receive in benefits. Lindo (2011) finds extremely negative effects of paternal unemployment, though again, it is not clear what policy response could best prevent or address this. This result does point to the importance of fathers, a topic that has generally been neglected in the literature.

Currie and Walker (2011) and Currie et al. (2013) show that exposure to pollution during pregnancy has particularly negative effects on the developing fetus. The cost of pollution control varies greatly depending on exactly how it is done. One option that has not been explored a great deal to date is the potential role of zoning to keep residences, schools, and child care centers away from sources of pollution such as busy highways. Over time, zoning changes might accomplish a lot in terms of health protection at a relatively modest cost. Improvements in filtration by daycare and school HVAC systems are probably cheaper still.

The second panel of Table 6 briefly summarizes shocks that have been shown to affect future test scores. Perhaps unsurprisingly, the same things that have an impact on low birth weight often have significant impacts on test scores. Black et al. (2014), Milligan and Stabile (2011), Dahl and Lochner (2012) all show that small increases in annual income in childhood has measurable effects on children's test scores. Sanders (2012), Bharadwaj et al. (2016), and Black,

Butikofer, Devereux, and Salvanes (2014) further explore the effects of pollution, while Aizer, Stroud, and Buka (2016) highlight negative effects of maternal stress during pregnancy on test scores.

Almond, Mazumder, and Van Ewijk (2015) and Greve, Shultz-Nielsen, and Tekin (2015) focus particularly on mild nutritional deprivation during pregnancy and find large negative effects on test scores. It would be particularly interesting to tie this literature on mild nutritional deprivation together with the literature on nutritional supplementation (e.g., analyses of the U.S. WIC program) to draw inferences about the potential effects of small variations in nutrition during pregnancy.

Turning to shocks in early childhood that have been shown to impact the wages of young adults, panel C of Table 6 points once again to some of the same suspects. Policies to improve immunization for influenza (Schwandt, 2016), reduce alcohol consumption in pregnant women (Nilsson, 2015), and reduce exposure to pollution (Isen et al., 2015) hold considerable promise. Maternity leave in very early childhood (Carneiro et al., 2015), child care subsidies (Havnes and Mogstad, 2011), and health insurance coverage for young children (Brown et al., 2015) all appear to have payoffs down the road. The Gertler et al. (2014) study of psychosocial stimulation applies to very disadvantaged children in a developing country. Yet there may be parallels to nurse home visiting programs that target disadvantaged parents in the U.S. and many developed countries.

Clearly, we cannot pin down specific cost-benefit ratios without a lot more information. But arguably we have still learned quite a bit about the types of interventions that could be expected to make children healthier, smarter, and more productive as adults.

That said, there remains a great deal of room for future research. More progress could be achieved if some of the measurement problems could be addressed. Some of our most widely used measures, such as low birth weight, are at best only proxies for a whole range of subtle damages that a developing fetus may have suffered. Without sensitive and specific “real time” measures of how someone has been harmed, and how interventions are affecting them, all we can do is wait and see what the eventual outcome will be. In addition to specific measures of harms, knowing more about how intermediate outcomes are affected could help us to identify individuals in need of assistance more quickly, and to target interventions more effectively.

Similarly, being able to identify sensitive or critical periods when particular shocks have their greatest impact, would be extremely helpful. To date, we have learned that the *in utero* period is itself an especially critical and sensitive period of an individual’s life. But breaking this period down further and learning more about critical periods in early childhood would also be extremely useful. If the early stages of pregnancy matter most, does starting WIC a few weeks earlier have a high return? Does fostering earlier recognition of pregnancies help?

Another area that could benefit from more precise measurement concerns the development of non-cognitive skills. A few of the studies discussed above focus on non-cognitive skills, and there is growing evidence that such “soft” skills matter a great deal in terms of producing “hard” outcomes such as educational attainment and employment. Yet these skills are typically represented by a hodge-podge of different measures that happen to be available to researchers and there is no consensus as yet on which measures are best or how to get a comprehensive overview of an individual’s non-cognitive skills.

We have emphasized that there is often considerable heterogeneity in the effects of a given shock. Most often, more disadvantaged people suffer greater harms, though not always. It is perfectly reasonable that there should be heterogeneous effects given differences in endowments, budget constraints, and available production technologies. Yet in many cases effective interventions may depend on knowing the source of the heterogeneity, something we can largely only speculate about now. Moreover, as we have discussed, families may act either to magnify or mitigate the effects of initial shocks. Hence, a greater understanding of the way that shocks and disadvantage interact, and of the role of parents in responding to them, is highly desirable.

To date, most of the literature focuses on the role of mothers, largely because we have had much better information about mothers than about fathers in many data sets. As large administrative data sets have become increasingly available, it has become possible to explore the role of fathers, but this exploration is only just beginning.

Similarly, improvements in the availability of data are making it possible to explore intergenerational effects. Given evidence from animal models, it is highly likely that changes in the fetus or young child could be passed on to the next generation. This type of mechanism could offer an additional reason for the intergenerational persistence of poverty, and for the existence of poverty traps in some disadvantaged areas.

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel A: Nutrition Shocks				
Adhvaryu et al., (2016). Effects of introduction of iodine fortification in the U.S. on age 25-55 education and labor market outcomes.	1) Census 1950-1980 that provide data on educ, wages, N= 418,791 obs. 2) Data on the geographic distribution of iodine deficiency prior to salt iodization comes from spatial distribution of goiter in 1924.	DD: Compare cohorts exposed in-utero (1920-1927) to iodized salt with those slightly older (& unexposed) (1928-1931), across states with high vs. low iodine deficiency rates prior to the salt fortification. Models include rich controls, region*birth year dummies, & year of birth FE & region of birth FE using 9 Census Bureau divisions.	Labor force participation: +1.35pp (2.2%=0.03 of a SD) (women: 1.63pp). Positive wage earning: +0.8pp (2.0% = 0.016 of a SD). No significant effects on education. Income quintiles: the likelihood of being in the 2nd wage income quantile rose by 0.35 to 0.68pp more during and after the roll out of iodized salt in high goiter compared to in low goiter states.	Results are driven by impacts on women: salt iodization accounts for 5% of the rise in female participation btw 1950 & 1990. Effects on LFP were larger in the 1st & 2nd income quintiles: effect = 1pp.
Almond and Mazumder (2011). Effects of exposure to Ramadan fasting on birth outcomes and adult disability, education, and mortality in Michigan, Iraq, and Uganda.	1) Census data for: Iraq 1997; N=250,000 (Muslims: 11%), Ages 20-39 Uganda 2002; N= 80,000 (Muslims: 11%), Ages 20-80. 2) Michigan Natality data, universe of births, 1989-2006, N~2.5M birth records.	Exploit the timing (month) of Ramadan as a natural experiment in diurnal fasting and fetal health. DD model: compare Muslim outcomes (treatment) to non-Muslim outcomes (control). Identifying assumption: pregnancies are not timed relative to Ramadan along unobserved determinants of health. Models include controls for month of birth FE, geographic location FE, and rich individual controls (estimates are ITT).	Exposure to Ramadan: BW= -18gr for Arab-named pregnancies (-0.6%). Effects by trimester: -21, -26, 0 grams, effects by month: -40 grams in first 2 months of pregnancy & in months 5th/7th significant effects. Adult disability: +22% (eff. in 1st month only, driven by mental or learning disabilities.) Mortality: "due to aging" +0.37pp (~+70% wrt the mean). Wealth: -2.6pp, -2.1pp less likely to own a home (males only). Education: no effects.	Most of the estimated effect of early pregnancy exposure is in the middle of the distribution. No gradient in BW by maternal education, Medicaid use, or month prenatal care was initiated. Effect sizes are similar in Uganda and Iraq.
Almond, Mazumder, and Van Ewijk (2015). Effect of exposure to Ramadan fasting in utero on age 7 schooling attainment in England.	1) England's Register data "Key Stage 1 scores", students' academic performance for those who attend state schools, 1998-2007. 2) Pupil Level Annual School Census (PLASC), covers all enrolled pupils in each year, includes demog & socioeconomic characteristics including ethnicity. Authors link data on the Key Stage 1 scores to the PLASC for e/year using unique student identifier from 2002 onwards and a 2-step matching process prior to 2002. N=326,592 obs.	DD strategy: authors take the effect on Muslims and use and non-Muslims to control for possible seasonal effects. Design exploits the fact that Ramadan moves through the calendar. Control group: Caribbean students. Models include child's state of birth*child's YOB FE, cubic time trend of the N_days between the DOB & January 1, 1960. Authors also fully interact each regressor (except for the geographic FE) w/a dummy for Muslim.	Ramadan exposure in the 1st trimester: Test scores (math, reading, & writing "Key Stage 1"): -0.05 to -0.08 of a SD. By months of pregnancy: Math: -0.068, -0.059, -0.081 of a SD in 1st, 2nd, & 3rd months of pregnancy (no effects in other months). Reading: -0.054, -0.067, -0.073 SD. Writing: -0.052, -0.053, -0.055 SD. Effects rise monotonically over the course of the 1st trim; largest effects in 3rd trim. Estimates are downward biased to the extent that Ramadan is not universally observed.	NA

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel A: Nutrition Shocks				
Feyrer, Politi, and Weil (2013). Effect of introducing iodine fortification in the U.S. in 1924 on military skill levels (young adult males) and thyroid related deaths.	<p>1) Statistics from draft physicals for WWI, include info. on the incidence of goiter prior to treatment for 151 regions.</p> <p>2) Dataset of men who enlisted in the Army during WWII; indicates who was drafted into the Air Force (highly skilled) vs Ground Forces (less skilled) based on an Army General Classif. Test (AGCT), source: National Archives & Records Administration</p> <p>N=2 million records in 1938 - 1946.</p>	<p>Compare cohorts born just before & after iodized salt introduced in 1924. Two sources of variation: i) pre-existing (<1924) iodine deficiency; ii) timing of the intervention.</p> <p>Also exploit the fact that the Air Force was assigned draftees w/higher test scores than Ground Forces. This non-random assignment is key for identification strategy.</p> <p>Linear Prob (& Logit) Models include interaction of goiter in 1924 in region of birth * YOB dummies, YOB dummies * enlistment year dummies, enlistment month dummies.</p>	<p>Individuals born in 1925 & 1926 (introduction of iod. salt was in 1924):</p> <p>Prob (being assigned to Air Forces- indicator of high skill): +0.3 to 0.6pp (full sample); +2.5-8.7pp (individuals in initially high goiter areas).</p> <p>Thyroid-related deaths: +10,000 in 1925-1942 (older groups more affected because they were iodine deficient for a longer period). Note: In 1926 death rates were >6 times as high for women as for men though sample is male.</p>	NA
Fitzsimons and Vera-Hernandez (2013). Effect of breast-feeding in the U.K. on cognition and health at age 7.	<p>UK Millenium Cohort Study; 9 months (2000/2001), 3 years (2004/05), 5 years (2006), 7 years (2008). Data includes hour of child's birth.</p> <p>N= 18,500 babies born (sample excludes C-section deliveries).</p> <p>Authors corroborate data w/Maternity Users Survey a postal survey conducted on 26,000 mothers, 3 months after birth.</p>	<p>Instrumental variables: Exploit timing in day of the week children are born (children born on weekend or just before, are less likely to receive breast feeding support services).</p> <p>IV: instrumental variable is being born on a weekend.</p>	<p>Breastfeeding has large effects on cognitive development, but NOT on noncognitive skills or physical health.</p> <p>Breastfeeding:</p> <p>Cognitive dev index: +0.6 of a SD.</p>	NA
Greve, Schultz-Nielsen, and Tekin (2015). Examine the effect of Ramadan fasting on student outcomes in Denmark.	<p>1) Danish administrative records on Danish, English, Math, & Science test scores in 9th grade.</p> <p>2) Danish birth registry, which includes exact info on gestation length and birth date</p> <p>N=11,291 children.</p>	<p>DD: exploit the overlap between time in utero of children born in Denmark with the month of Ramadan.</p> <p>Treatment group: children born to immigrant parents from predominantly Muslim countries</p> <p>Control group: children born to immigrant parents from predominantly NON-Muslim countries.</p>	<p>Child is Muslim*Child was exposed to Ramadan:</p> <p>No overall effects on Danish, English, Math or Science test scores. Authors estimate models by gender & by gender-SES.</p>	<p>Estimates are larger for girls and for children of lower socioeconomics status mothers.</p> <p>Danish test scores: -1.08 SD (females and low SES children).</p> <p>English test scores: -1.84 SD; -1.6 SD (females and low SES children).</p> <p>Math test scores: -1.04 SD; -0.98 SD (males and low SES children).</p>

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel A: Nutrition Shocks				
Hoffman (2014). Effects of Ramadan Fasting in 7 Muslim countries on sex ratios of 0-60 month olds.	DHS data from 7 Muslim countries, 1987 - 2013; N=275,627 births.	Exploit variation in the timing of Ramadan throughout the year, across countries. Treatment group: individuals exposed to Ramadan (at least 1 month) during gestation, controls not exposed. Models include month of birth, year of birth, & country FE, & country-specific time trends, mother's FE.	Exposure to Ramadan during pregnancy: Prob(child is a girl): +2.4% (+ 0.024 SD). Exposure to Ramadan in the first 3 months of pregnancy: Prob(miscarriage): +1% (0.004 SD). No effects on neonatal death or infant death.	Effects somewhat larger in rural areas and in mothers without primary education. e.g., for less educated mothers: P(child is a girl): +3.4% (+0.035 SD) P(miscarriage): +1.7% (+0.017 SD) P(neonatal death): no effect P(infant death): 1.4% (0.014 SD) (driven by exposure to Ramadan in the month of birth).
Linnemayr and Alderman (2011). Effect of nutritional supplementation in Senegal on weight for age for children 0-3.	Baseline survey conducted in April 2004 in 212 villages, includes info on health status of children, SES of the children's household, nutrition, child care, etc.; follow-up in 2006; N=200,000 households.	1) DD comparing 111 treatment and 110 control villages. 2) IV: use planned treatment assignment as an instrument for actual treatment. 3) Propensity score matching across treatment and control villages. Models include initial village-level characteristics (e.g., distance to the next village), interactions of village characteristics and planned treatment, dummies for child age.	Weight-for-age: Using DD model: +0.1 SD Using IV: +0.31 SD (effect only observed on children <6 months). Using PSM: +0.27 SD	By child's age: authors find significant weight gain for younger children (these children were impacted in utero). "Most malnutrition occurs by 18 months w/limited catch-up after that."
Ludwig, Rouse, and Currie (2013). Maternal weight gain during pregnancy and child BMI in Arkansas.	1) Vital Statistics Natality data: universe of births in Arkansas 1989-2005, N=42,133 women (91,045 offspring). 2) State mandated data on childhood BMI from public schools (August 18, 2003 to June 2, 2011).	1) Exclude pre & post terms, multiple gestational N, maternal diabetes, & extremes in BW's. 2) incorporate measured confounders in models. 3) Sibling FE design. Models include rich maternal controls, month of child's age, & year of birth FE.	One additional Kg of pregnancy weight gain: Childhood BMI: +0.022 (0.06% = 0.004 of a SD). Childhood overweight/obesity: OR increased by 1.007. Variations in pregnancy weight gain accounted for a 0.43 kg/m ² difference in childhood BMI.	NA
von Hinke Kessler Scholder et al, (2014). Examines short and long-run effects of maternal alcohol consumption during pregnancy.	1) Avon Longitudinal Study of Parents and Children (ALSPAC); Panel follows cohort born in Avon, England in ~1991-1992. N=4,088 children. 2) Children's scores are obtained from the National Pupil Database, a census of all pupils and measured at 7, 11, 14, and 16.	Exploit genetic variation in the maternal alcohol-metabolism gene ADH1B to instrument for fetal alcohol exposure. Authors claim that at a population level, genetic variants are unrelated to socioeconomic characteristics. Instrument: dummy for whether an individual carries either one or two copies of the rare allele. Models control for child's genotype on the same variant, and for the ancestry-informative principal components.	Exposure to an additional unit of alcohol (instrumented by mother having the rare allele): 1st stage: Mothers who carry the rare allele are -11 to -15pp less likely to consume any alcohol during pregnancy (-53% w.r.t. the mean). Key Stage examination test scores (at ages 7, 11, 14, 16): -0.2 to -0.3 SD (no mean stats provided to compute % changes of the coefficient).	Estimates are slightly larger for children of lower education and lower income mothers. No difference by gender or partner's social class at birth.

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel B: Stress				
Aizer (2011). Impact of domestic violence on birth outcomes in California.	Hospital admissions for assault during pregnancy in CA, 1991-2002 matched with universe of births in CA. N~500,000 pregnant women/yr.	2 challenges: i) possible omitted variables bias, ii) non-random under-reporting of domestic violence. Author uses: i) IV: A control function where IV is the enforcement of laws against domestic violence across jurisdictions, ii) Matching estimates on many covariates (n=1,542 women matched). Models include rich indiv controls, county*year dummies, a quadratic in year, county FE for the 5 largest counties in CA.	As criminal sanctions increase, domestic violence declines. Using control func. method: BW: -163gr due to hospitalization for an assault while pregnant (OLS models predict a BW decline of -161gr). Effects of violence on BW are larger in 1st half of pregnancy than in 3rd trim's (-166, -118, & -97gr in e/trim respect.) Using matching: BW = -159gr	NA
Aizer, Stroud, and Buka (2016). Examine relationship between measured cortisol levels during 3rd trimester and education at age 7.	National Collaborative Perinatal Project (NCPPI); mothers cortisol levels were measured in 3rd trim and their children were followed up to age 7; years of birth: 1959 to 1965, sample used in study are 2 cities: Boston and Providence. N= 1,093 pregnancies (368 siblings).	Regression model w/indicator of cortisol exposure in pregnancy and rich individual controls and sibling FE.	Being exposed to highly elevated cortisol in-utero: Education: -0.39 to -1.1 yrs of schooling (0.58 of a SD) (sibling FE)	Children born to mothers without a HS degree & exposed to highly elevated cortisol in-utero: Education: -2 yrs of schooling (sibling FE). No effect among children of more educ moms.
Currie and Rossin-Slater (2013). Effect of stress due to potential hurricane exposure during pregnancy on infant health outcomes in Texas.	1) Vital statistics, 1996-2008, includes info on mothers' names, DOB, & residential addresses (helps identify mothers who were in the path of major tropical storms & hurricanes), child's exact DOB, county of birth N= 1,270,441 births 2) Data on hurricanes come from the Weather Underground Hurricane Archive; publicly available.	Exploit the temporal & geographic variation in the occurrence of hurricanes in Texas. Mother FE (to account for mother's time invariant characteristics) with IV to account for a mother's endog. migration in response to a hurricane. Instrument is a mother's county of residence in 1st pregnancy.	Exposure to hurricanes: No effects on LBW or gestation. Prob. of abnormal cond.: +60% (including meconium aspiration syndrome or being on ventilator >30 min). Prob. of having complications during labor/delivery: +30%.	NA

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel B: Stress				
Lee (2014). Intergenerational effect of stress mother suffered while in utero (due to Kwangju uprising in Korea) on her children's birth outcomes 20 to 22 years later.	1) Korean vital statistics, 2000 & 2002, N=1,124,848 births.	Natural experiment: Massacre of >500 civilians and wounding of 3000 in the Kwangju (KU), Korea in 1980. DD: Assume that individuals whose mother resided in Kwangju in May 1980 & who were born between June 1980 & February 1981 were exposed to stress caused by the violence in utero. Models include cubic time trends, and rich mother controls.	Exposure to the KU shock by trimester of pregnancy: BW: -37grams (-1.1%) (1st trim), -105 grams (-3.2%) (2nd), no effect (3rd trim) LBW: +1.7% (1st trim), +4.0% (2nd trim), +1.3% (3rd trim) Preterm: no effect (1st trim), +4.6% (2nd trim), +1.5% (3rd trim).	NA
Persson and Rossin-Slater (2016). Asks how death of a family member during pregnancy affects birthweight, mental and physical health, hospitalizations, and income up to age 30.	1) Universe of children in Sweden in 1973, 1977, 1983, 1988, 1995, 1999, 2001, & 2005. Link child to information on siblings, parents, grandparents, aunts and uncles and maternal great-grandparents. Review cause of death register for all family members, combine with information about child's exact DOB, birth outcomes and later health outcomes as well as income and taxation register with labor income up to age 30. N=63,756 obs.	Exploit the quasi-random variation in the exact timing of bereavement relative to the child's expected date of delivery at full-term. Models include year & month of conception FE, & municipality where a mother lived at conception of child FE.	In-utero exposure to the death of a relative: Mental health outcomes Uses prescription drug: +6% (No standard deviations of outcomes provided) Uses anti-anxiety drugs: 11% Uses anti-depression drugs: 9% Daily dose of ADHD med.: 23% BW: -18gr (-0.5% = -0.03 of a SD) (eff driven by lower tail of distrib) LBW: +20%; VLBW: +30%; Preterm: +15% No significant effects on physical health or income.	NA
Quintana-Domeque and Rodenas-Serrano (2016). Effect of in utero stress due to terrorist attacks in Spain on birth outcomes.	1) Vital stats; live births conceived btw 1980-2003; N=6.5 million live births 2) The Victims of ETA Dataset: provides the N of casualties committed by ETA between January 1980 & February 2003 in each day & region Datasets merged at the trimester and province levels.	DD: exploit the variation in casualties across provinces (50 geographical regions) & months-years (more than 275 conception month-years) Models include mother's province of residence FE, year & month of conception FE, a vector of control variables (birth order, mother's age, marital status, etc.), size of the municipality of residence categories, province-specific linear time trends.	1 additional bomb casualty in the 1st trimester of pregnancy: BW: -0.7grams (-0.02%) (no standard deviations provided in Table 1) Prematurity: +0.9 per 1,000 live births (-0.02%) Normality: 0.6 per 1,000 live births. Results are driven by exposure to terrorism in the 1st trimester.	By gender: no differential effect for both boys and girls (results not shown).

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Disease				
Almond, Currie, and Hermann (2011). Effect of disease environment as proxied by postneonatal mortality rates on the health of women observed in the U.S. vital statistics natality data.	U.S. vital statistics natality & mortality records: authors are able to link the post-neonatal mortality rates in the mother's state of birth & provide info on outcomes of mother & infant. 1) Vital Statistics natality microdata, 1989–2006, N~3.5- 4 million births/yr 2) Mortality microdata, 1960–1991.	Exploit the geographic & temporal variation in post-neonatal mortality rates (across racial groups) from 1960 to 1990 in 5 large states . Aggregate data into cells by mother's state and YOB, age, and race, and child's state and YOB. Regression models (defined at the mother's race, state of birth, in YOB & yr, state, age that mother gave birth) include mother characteristics, mother's state of birth FE, child's YOB *child's state FE, maternal single year age FE, mother's state of birth linear time trends, linear time trends in maternal age FE.	An additional postneonatal death per 1,000 in the year after mother's YOB: Health: Diabetes: 1.8% (0.009 of a SD); 1.4% = 0.007 of a SD (whites), 3.5% = 0.012 of a SD (blacks). Hypertension: no effects SES: Educ attainment: -0.1% (-0.012 of a SD) Married: -0.6% (-0.009 of a SD) Maternal behav: smoking +2% (-0.02 of a SD); high weight gained 1.7% (0.01 of a SD).	Larger impacts for blacks than for whites. The mean PNMRT+1 for whites (4.0) and the mean PNMRT+1 for blacks (8.4) suggest that the early life disease environment increased the probability of diabetes during pregnancy almost 30% for blacks compared to 5.6% for whites.
Baird, Hicks, Kremer, and Miguel (2016). Effects of deworming on test scores and anthropometrics of 8-15 year old children in Kenya.	1) Longitudinal data from 75 rural schools treated 1998-2001. 2) Kenya Life Panel Survey (KLPS) 2007-2009, tracked N=7,500 respondents who had been enrolled in grades 2-7 in the 75 treated schools at baseline in 1998.	Reduced form model: includes dummy for treatment, N of treatm pupils in 6Km, & N of treatm schools in 6Km & baseline indiv & school characteristics. Estimate exposure to spillovers using the N of pupils attending deworming treatment schools within 6Km, conditional on total N of primary school pupils within 6Km.	Health: Self-reported health is v. good: +4.1pp (+0.085 of a SD); Prob of miscarriage: -2.7pp (-0.69 of a SD) (females only). Education: yrs of schooling +0.3 (+0.10 of a SD), English vocab. tests +0.076 of a SD. Labor market outcomes: work hours: +1.76hrs = 12% (+0.12 of a SD); wages: +30.1 log points = 3.8% (0.36 of a SD). Shifts in employment towards full-time jobs with higher wages (i.e., manufacturing) (males) & away from casual labor & domestic services (females).	No differences in labor supply effects by gender or by age or by initial infection rate. Externality effects: an increase of 1SD in local density of treatment school pupils (917 pupils= treating 20% of local primary school pop), leads to: +3 hours worked/wk
Beach, Ferrie, Saavedra, and Troesken (2016). Typhoid rates in 3-yr MA around birth on adult education and earnings.	1) Census data of 1900 & of 1940. 2) City-year level typhoid fatality rates for 75 cities (source: Whipple (1908); 10th annual Census mortality statistics). N=189,515 obs.	Exploit variation in typhoid fatality rates during early life as a proxy for water quality. Instrument typhoid fever using lagged city-level typhoid rates that lie upstream). "Cities that dump their sewage into a river will increase future typhoid rates for cities downstream." Models include controls for being black, city & year of birth FE, birth order FE.	1st stage: Lagged typhoid rates in the feeder city are a strong predictor of typhoid rates in the receiving city (F-stat>517.81). Educational attainment: +1 month of schooling (OLS) (0.9%=0.026 of a SD) (no effect obtained from IV). Earnings: +1% (OLS) (0.012 of a SD); +9% (IV) (0.10 of a SD). No effect on home owning.	NA

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Disease				
Bhalotra and Venkataramani (2013). Effects of diarrheal disease on test scores of children in Mexico at age 9-15.	1) Mexican Family Life Survey (MxFLS), N=8,500 HHs in 150 communities in 16 states, waves: 2001-2002; includes month & year of birth, birth state, indicators of HH wealth, parental investment. 2) PISA Test score data: waves 2003, 2006 & 2009 for cohorts born in 1987/1988, 1990, & 1993; includes school quality, parental investments. 3) Census micro-data 1960-2000 from IPUMS (to study empl. & occup. trends by gender).	Reduction in the risk of waterborne disease from a major water reform in Mexico in 1991. Reform introduced suddenly in reaction to threat of cholera in neighboring countries. Exploit state*yr variation in program intensity. DD model: includes respiratory disease as a control disease un affected by the reform but a leading cause of child morbidity & mortality. ITT estimates identifying assumption: test scores are uncorrelated w/the timing of the water reform. Models include indiv controls in pre-1991*dummy Post, state & year of birth FE, state time trends.	A 1 SD reduction in childhood diarrhea mortality rates: Test scores (Raven): +0.1 of a SD (0.6%) (girls only) Reading: 0.04 of a SD (+0.7%) (girls only) Math: 0.05 of a SD (+0.8%) (girls only) A 1 SD decrease in diarrheal mortality rates in childhood reduces gender gap by 80% (MX gender gap smaller than the OECD avg gap: 11 in 500 points).	Effects are driven by low SES girls.
Bhalotra and Venkataramani (2015). Examine the impacts of pneumonia in infancy on adult (males) education, employment, disability, income and income mobility.	1) US Census micro data for 1980-2000; authors focus on men only who were born born between 1930-1943; N=2,018,898 men (of which less than 10% are Blacks).	Exploit state variation in 1937 in the introduction of sulfa antibiotics to prevent pneumonia. Treatment group: cohorts in their infancy in 1937 or later. Control group: cohorts in their infancy before 1937. Models include an interaction between: (the pre-sulfa pneumonia mortality rate in the birth state in 1930-1936) * (Dummy for cohorts who were in their infancy in 1937 or later) Models include indiv controls, birth state & birth year varying observables, state linear time trends.	A 1 SD decline in pneumonia exposure in the birth state due to the introduction of antibiotics: Years of schooling: +0.1 (no SD provided in paper) HS completion: +1.5% College completion: +1.2% Cognitive disability: -0.6% Work-related disability: -0.6% Employment: +0.4% Income: +1.5% Having income in the lowest quintile: -0.47% Having income in the highest quintile: +0.41%	By levels of institutional-racial segregation: "Black men born in the least segregated states reaped substantial gains from infant exposure to sulfa drugs, while blacks born in the more segregated states saw muted gains".

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Disease				
Currie and Schwandt (2013). Shows that there is seasonality in health at birth within mother and that this may reflect seasonal flu epidemics.	1) Vital Statistics Natality data in NJ (1997-2006), NYC (1994-2004), & PA (2004 -2010). N=647,050 pairs of siblings (1,435,213 children). 2) Info. on prevalence of Influenza is obtained from the Center for Disease Control (1997-onward).	Analyze the seasonality of health at birth by comparing siblings conceived by the same mother at different times using sibling FE. Compare impact of coming to term in early winter in high flu and low flu years.	Conception from Jan. to May is associated with significant reductions in gestation (-0.08 week) and prematurity within families: +1pp (13.2%). Birth weight falls by -4gr (increases by 8gr if conception occurs in June-August). More severe flu seasons show stronger effects. In children coming to term in high flu season the risk of negative birth outcomes is much higher, suggesting that exposure to flu late in pregnancy causes preterm delivery.	The seasonal pattern in health outcomes is observed across SES, child gender, & birth order groups.
Oizer (2014). Spillover effects of the Kenya deworming program measured at ages 8-15.	Data on children were collected in 2009 and in 2010 at all of the deworming project schools in Samia and Bunyala districts of Kenya's Western Province; includes N= 20,000 children with info on collected height, weight, and migration status; and 2,400 children, cognitive measures were collected.	"Conditional on child's age & data collection year, deworming exposure was randomized." Treatment group: children born in 1998 in communities w/ the deworming program. Control group: children born in 1998 in a community w/out the deworming program (the program only started to operate in 2001 in control communities, i.e., when these cohorts were age 3).	Community deworming before age 1: Raven's matrices: +0.22 of a SD PPVT: no effect Verbal fluency: +0.19 SD. No effects on height. "That Raven's Matrices are responsive to the intervention suggesting that even mild disease burdens early in childhood can alter cognitive development."	By gender: no differences. By differential exposure within the HH: Having older siblings in an affected school: Raven's matrices +0.42 SD. Having older female siblings in an affected school: Raven's matrices +0.84 SD (females more likely to care for younger siblings).
Schwandt (2016). Effect of maternal hospitalization for influenza during pregnancy on earnings, welfare dependance, etc. at 19-32 in Denmark.	1) Danish Birth Records, 1980-1993; N= 700,000 births. 2) Income Register & Population Register, 1980, 2012; ages 19-32. 3) National Patient register, 1980-2012, ages 18+; used to link births to maternal hospitalizations during pregnancy; this dataset helps identify influenza-like illness infections in pregnant women. Datasets are merged using personal identifiers.	Exploit the variation in seasonal influenza in the month of conception. Models include individual controls & mother-FE. Author also uses an IV strategy: instrument for 3rd trimester influenza exposure to correct for the potential bias that a shorter duration of pregnancy is correlated with a shorter period in which a mother can be infected by influenza.	Influenza admission during pregnancy (dummy): BW: -77grams (-2.2% = -0.14 SD). LBW: +2.9pp (+66%). Gestation (weeks): -0.3 (-0.8% = -0.17 SD). Preterm: +4pp (+88%). Sex ratio: no effect. LT outcomes: Earnings: -10% (0.09 SD). Labor force participation: -7%. Welfare dependance: +43%. Labor mkt outcomes are driven by exposure in 2nd & 3rd trimesters.	By mother's educ: Children of mothers w/ low educ are less likely to be in school (at ages 18-20) & have fewer yrs of educ compared to children of other moms. Effects are driven by influenza admissions in the 3rd trimester.

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Disease				
Venkataramani (2012). Effects of malaria exposure in Mexico on adult cognition.	1) 2002 Mexican Family Life Survey; N=1,649 men and 2,184 women. Data include test scores, employment, HH & individual income, expenditure, education, anthropometrics, morbidity, health care utilization, migration. 2) State-level data on the avg death rate (per 100,000) from malaria 1949-1953 (erradication began in 1957).	Exploit the nationwide introduction of malaria eradication efforts in Mexico: DD Strategy: compare the change in outcomes btw cohorts born before & after the intervention in areas that benefited more from the policy against the same change for cohorts born in less malarious regions. Models include state and year of birth FE and birth state specific linear time trends, individual controls.	Birth year exposure to malaria eradication: Raven Progressive Matrices test scores: +0.11 to 0.22 SD (+25 to 51%). Household consumption expenditures: +6.5 to 13.6%. Total Schooling: no effect. Cohorts affected by the policy entered and exited school earlier: Age at school entry: falls by -0.15 to -0.37 years. Age @school exit: falls by -0.55 to -1.06 years.	By gender: effects are only observed for men.
Ward and Phipps (2014). Exposure to flu in utero on health and cognition of 4-5 year old children in Canada.	1) National Longitudinal Study of Children and Youth (NLSCY), 1992- (week 37) to 2011 (week 34), N=11,888. 2) Rate of laboratory confirmed influenza includes influenza laboratory surveillance rates, from the Canadian Respiratory Virus Detection/Isolation Surveillance System (RVDI). 3) Hospital counts from records of inpatient discharges, 1996-2006; & Google Flu Trends data.	Exploit the weekly variation in Influenza surveillance rates across provinces to estimate effects of exposure during gestation on child cognition & health. Models include the Influenza term & its square to capture nonlinear effects. Also year, month, & province FE, seasonal factors & individual characteristics. Conception date: N of gestational weeks before e/child's DOB where gestational length is based on the date of the mother's last menstrual period.	An increase of 1 SD from the mean Influenza surveillance rate (in the whole pregnancy) has no statistically significant effect. The effect of each week of Influenza during the 1st trimester (13 week-period): PPVT: -1.1pp (1.1% = 0.07 of a SD) Chronic condition: -2.8pp (-14.7% = -0.08 of a SD).	NA

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel D: Pollution				
Black, Bütikofer, Devereux, and Salvanes (2014). Ask how prenatal exposure to fallout from above ground nuclear testing in the 1950s and 1960s affected IQ, earnings, and education at 18-35 years in Norway.	1) Norwegian registry data covers the population of Norwegians up to 2009 (education register, family register, tax and earnings register); N=37,000. 2) Norwegian military records, provides IQ scores for men only; N=94,649. 3) Norwegian Defense Research Establishment : Total beta radiation in the air expressed as Bq/m3, and (ii) total beta radiation on the ground) expressed in Bq/m2.	Regional fallout was determined by wind, rainfall, & topography. Significant fallout in 1957-1958 & in 1962 -1963. Authors compare individuals born within the same municipality but born in diff. month/year of birth (and thus exposed to different levels of radiation in utero). Models include individual/family charact,municipality of birth FE & YOB* month of birth FE's, municipality linear trends, interactions between municp*yr, & munip*month sibling FE.	A 1 SD increase in monthly exposure to ground(air) radiation: Male IQ scores: -0.04 (-0.06) of a SD (effect size: -2% (-1%) of a SD) (exposure in months 3 & 4). Yrs of schooling: -0.08 (-1%) (men), -0.1 (-1%) (women) (exposure in months 3 & 4). Earnings and adult height: negative although weak effects. Intergenerational transmission of HK: Exposure of parents in utero leads to Son's IQ: -0.025 of a SD (no effect for daughters).	Little evidence for non-linearities (the estimates are monotonically increasing in magnitude w/quintile); only for quintiles 3-5 of exposure that there are any significant negative impacts of radioactive fallout. Effects are greater for individuals born to more highly educated parents.
Currie (2011). Asks whether minority and less educated mothers are more likely to be exposed to toxic releases from plants and/or Superfund sites during pregnancy in 5 large U.S. states.	1) Individual-Level Natality Data, 5 large states (FL, MI, NJ, PA, & TX), 1989 (N= 3,948,042 singleton births) & 2006 (N=4,121,898); data include a mother's residential location. 2) Data on pollution: Superfund sites (see column J) & facilities listed in the EPA TRI.	DD model: Exploit timing in exposure to the pollution cleanups & the distance of mother's residence to pollution sites. The treatment is "Close x (After Cleanup)" which represents the extent to which the area surrounding a Superfund site became "Y" (e.g., "whiter") after a cleanup. Models include rich mother controls & controls for county & yr of child's birth FE. Also examine effects of information about toxic release inventory sites on migration.	Following cleanups, mothers in the immediate vicinity of a Superfund site are more likely to be: "white college educated" mothers: +10.1%. Also, white college educated mothers are more likely to leave an area when new information about toxic releases is revealed -8.7%.	Whites and educated mothers are more likely to respond to information or changes in pollution levels, which may partially explain lower exposure levels.

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel D: Pollution				
Currie, Graff Zivin, Meckel, et al. (2013). Asks how potential exposure to contaminated drinking water affects birth outcomes in New Jersey.	1) NJ vital statistics natality data - all births, 1997-2007, include mother's residence, siblings matched using mother's full maiden name, race & birth date, father's information, & SSN; N=521,978. 2) Records of drinking water violations in NJ, 1997-2007. 3) Temperature & precipitation statistics. 4) Map of drinking water service areas in New Jersey.	Sibling FE with IV (instrument for actual contamination using the contamination that would have been experienced had gestation lasted exactly 39 weeks). Models control for temperature & other controls, & year*month of birth effects. Authors address the mechanical correlation btw gestation length, and exposures by using IV.	Living in a water district with contaminated water during pregnancy: using mother-FE + IV: LBW: +6% due to any chemical cont. +14% due to any contamination. Prob(preterm): no effects (full sample). Authors address the mechanical correlation btw gestation length & exposures by using IV.	LBW: + 14.6% (of a SD) for mothers with HS educ or less; Prob(preterm birth): +10.3% (of a SD) for mothers with HS educ or less.
Currie and Walker (2011). Estimate effects of E-ZPass (which reduced traffic congestion and vehicle emissions near highway toll plazas) on birth outcomes.	1) Vital Statistics Natality records from PA, 1997-2002. 2) Vital Statistics Natality records from NJ, 1994-2003. 3) Data on housing prices in NJ, 1989-2009 to test if housing prices. N= 412,884 observations. Authors know the exact addresses of mothers.	Exploit the introduction of electronic toll collection (E-ZPass). Diff-in-Diff: compare mothers within 2 km of a toll plaza to mothers who are 2 to 10 km from a toll plaza. Models include month and year of birth FE, toll plaza FE, distance to highway, and maternal characteristics.	E-ZPass adoption reduced NO2 by 10.8%, likely reduced CO by 40% near toll plazas. E-ZPass adoption (comparing children of mothers within 2 km of a toll plaza to those of mothers who are 2 to 10 km from a toll plaza): Prematurity: -9.0 %; LBW: -11.3%. A 1-4% decline in pollution from cars leads to a 1% decline in LBW.	African Americans only: Prematurity: -22.4% LBW: -29.5%
Ferrie, Rolf, and Troesken (2014). Asks how lead in the water supply in the early 20th century affected the intelligence of Army Air Corps members in WWII.	1) 5% sample of the 1930 U.S. Pop Census. 2) Data on assignment to the air corps among Army recruits during WWII. N=44,040 enlistees in 293 cities. 3) Data on pH level of water used by the public water company in the enlistee's city of residence & w/the enlistee's air corps status.	Authors use "enlistee's state of birth" to identify early-exposure to lead. Water with high ph creates scale in lead pipes which reduces lead in water. Models include year & state of birth FE, a dummy for SES and an interaction btw SES and both pH and pH-squared.	Intelligence (dummy for assignment to the Army Air Corps): The probability of assignment to air corps was significantly reduced when water pH decreased (below 7.5) or increased (above 7.5), and this U-shape relationship was particularly strong for enlistees from low SES backgrounds.	Living in a city with acidic water increases the probability that a recruit from a blue collar family was assigned to the air corps by 7%. No effect for recruits from white collar families. Similar contrasts observed comparing children from unemployed vs. employed fathers and in HH's with low rent vs. high rent.

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel D: Pollution				
Isen, Rossin-Slater, and Walker (2016). Effects of reductions in air pollution in non-attainment counties due to the 1970 Clean Air Acts on employment and earnings at ages 29-31.	Longitudinal Employer Household Dynamics (LEHD); 1998-2007, includes location & DOB. N=5.7M indiv.; universe of employed workforce quarterly earnings records; authors collapse data to the county*year (888 units in total). Earnings records: UI-covered earnings by employer/ quarter. Algorithm to match county of birth in LEHD to GNIS (95% of indiv. matched). 2) Authors match data to the REIS for county characteristics. 3) Authors match data to NCHS to examine infant health & use maternal, paternal, child characteristics.	Exploit sharp changes in ambient air pollution due to the implementation of the 1970 Clean Air Act Amendments (CAAA) to investigate effects of cleaner air on adult earnings. Compare cohorts born just before & just after the CAAA. Three methods: 1) reduced form model of the LT effect of TSP on earnings; these models include county FE, birth-state*year FE, indiv. controls. 2) two-step estimator: to construct group-level adjusted earnings (p. 9). 3) IV for air quality in county at birth. IV: dummy for the 1970 CAAA introduction at the county-year level.	A 10 unit decrease in TSP in-utero: Quarters employed: +0.7% Annual earnings: +1% Gains in lifetime income: +\$4,300 (using a 5% annual discount rate) (2008 dollars). Total wage bill attributable to improved early life air quality: \$6.5Bill. /cohort (2008 dollars). 1st stage: CAAA reduced TSP concentrations by 8-12 g/m3 (10% reduction; mean 95.9 g/m3).	By percentiles of the earnings distribution: most of the mean earnings effect is being driven by the bottom tail of the distribution (CAAA is associated with a decrease in the fraction of indiv. at the bottom tail of the distrib. & an increase in the fractions in middle parts of the distribution). Authors find little heterogeneity in effects of TSP on labor market outcomes across age groups (age 28, 29, 30, & 31). Little heterogeneity across gender, race (results not shown).
Knittel, Miller, and Sanders (2011). Ask how zip code level variations in traffic patterns affect infant health outcomes in California.	1) Vital statistics, 2002-2007, birth & death records. 2) Freeway Performance Measurement System (PeMS); traffic measures from freeways in Sacramento Valley, the Bay Area, & Los Angeles Basin. 3) EPA data on ambient pollution levels. 4) National Climatic Data Center info on ambient weather conditions. Authors collapse the data into mother zip code by birth week by total weeks survived cells; N=1,436,739 obs.	Exploit the relationship between traffic fluctuations, ambient weather conditions, & various pollutants (CO, PM10 micrometers, & ground-level ozone) at the week & zip-code levels in CA. Instrument for week-to-week pollution using zip-level traffic & zip-level traffic interacted w/linear & quadratic weather variables). Models include rich weather and individual-level controls, a flexible spline in age in weeks, zip_code FE, zip*month*year FE.	A one-unit decrease in PM10: Infant mortality: -18 lives per 100,000 live births (-6%). Neither CO nor ozone have a statistically significant impact on child mortality. 1st stage: local pollution instrumented by car traffic & the interaction btw car traffic & weather measures is strong; however, authors do not show results on 1st stage.	A one-unit decrease in PM10: Blacks: no effect (but perhaps few blacks in CA). Births covered by Medicaid: -23 lives per 100,000 live births (~-8%). Births to HS dropouts: -29 lives per 100,000 live births (~-10%).

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

<p>Sanders (2012). Asks how variation in pollution in the county and year of birth affects 10th grade math test scores in Texas.</p>	<p>1) Texas Education Agency (TEA) includes data on the Texas Assessment of Academic Skills (TAAS) & on the Texas Learning Index (TLI), 1994-2002, 10th graders; N=1,902,463 students in 416 schools across 30 counties .</p> <p>2) EPA database of historical air quality; includes readings from all pollution monitors within 20 miles of a county population centroid.</p> <p>3) Global Surface Summary of the day: weather data.</p> <p>4) REIS data on county characteristics.</p>	<p>Counties with more manufacturing saw greater decreases in pollution in the recession of 1981-1983. Instrument pollution levels using county-level changes in relative manufacturing employment.</p> <p>Instrument=TSPs as a function of all workers in a county employed in the manufacturing industry (SIC code 400) /total county employment levels in all other sectors in a given year. Estimates are LATE. Models include rich controls, school FE, year of test FE, school*year pupil-to-teacher ratios from the CCD. Data is collapsed by demographic group, school of attendance, year of birth, and year of test; regressions are weighted.</p>	<p>A 1SD decrease in TSP in a student's year of birth:</p> <p>High school test scores: 0.06 of a SD .</p> <p>1st-stage: a 1pp increase in the ratio of relative manufacturing employment increases ambient TSP levels by 0.61 $\mu\text{g}/\text{m}^3$ (F-test\sim33).</p> <p>IV estimates are larger than OLS estimates (0.06 versus 0.02 of a SD) which could be due to: measurement error & the fact that IV identify local effects.</p>	<p>Results are significant only in the periods of the most drastic pollution variation, suggesting a subtle relationship that may be difficult to separate from background trends.</p>

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel E: Weather				
Aguero (2014). Examines the effect of high temperatures at various ages in childhood on adult heights in Mexico.	ENSANUT: Mexico's health & nutrition survey; cross-section; includes e/person's age & location; nationally rep. waves: 2000, 2006, 2012. N=65,000. 2) Mexico's National Weather Service: includes meteorological stations across the country. 3) District-level poverty index from CONAPO. Match HH data w/weather info using the coordinates of each station & the district where each individual lives.	Exploit year-to-year variation in temperature across districts in Mexico. Author claims that the year-to-year variation in weather is orthogonal to other unobserved determinants affecting health status. Models include controls to approximate initial health endowment, FE's at the district, birth cohort, survey year, state time trends. Author reports effects of temp by stages: i) in utero (exposure in the year before birth), ii) infancy (ages 1-4), iii) childhood (5-9), iv) adolescence (10-15).	Hotter temperatures in infancy & adolescence (two periods when human growth is fastest) are negatively associated with adult height. Being exposed to hotter temperatures prior to birth & in childhood is NOT associated w/future height.	Author includes interaction terms with all the temperature variables: By gender: no differences. By district poverty level: negative effects of hot temp are stronger for individuals living in poorer districts. Hot temp help amplify health differences by SES.
Krutikova and Lilleor (2015). Variations in rainfall in rural Tanzania in 10 years around birth on outcomes at 17 to 28.	1) the Kagera Health and Development Survey (KHDS); Baseline 1991-1994 (915 households in 51 villages), 1st follow-up in 2004 (sample expanded to 2500 HHs); 2nd follow-up in 2010 (sample expanded to 3300 HHs). The last waves include the outcome of interest. Final sample N=897 individuals. 2) Rainfall data at the monthly - village level.	Exploit the geographic and temporal variation in rainfall across villages in rural Tanzania. Siblings FE models. The coefficient of interest is the effect of rainfall in utero, in 0-1, 1-2 years of life.	A 10% increase in rainfall from the LR avg: "Core self-evaluation" (relative to siblings): +0.08 SD. (Note: no descriptive table with outcomes to convert the coefficient). Effect is significant ONLY in utero and not in the first 2 years of life. By trimester: the effect is similar across all trimesters (beta= 0.08SD).	By gender: little difference in the effects of rainfall.

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel E: Weather				
Rocha and Soares (2014). Rainfall fluctuations in semi-arid parts of Brazil during gestational period and effects on birth weight and infant mortality.	1) Birth and mortality registration records used to create a municipality-by-month panel, 1996 -2010; N=188,640 obs. 2) Precipitation & temperature municipality-by-month weather data. 3) Census of 2000 & 2010: provides municipality info on the % of households w/access to piped water, sanitation.	Exploit variation in rainfall at the municipality & monthly levels. Health outcomes (measured as the municipality avg for children born in municipality i, on year y, month t) are regressed on average temperature in the municipality over last 12-months, municipality-by-month of birth FE, year of birth FE, & municipality-level trends.	A 1 SD increase in rainfall: Infant mortality: -5% w.r.t. the sample avg of 30 deaths/ 1000 births. BW: +1.6 grams (+0.05% = +0.03 SD). Fraction of full-term pregnancies: +0.3pp (+0.32% = +0.027 SD). Effects are stronger during the 2nd trimester of gestation, for children born during the dry season, & for mortality immediately after birth. Potential benefits from expanding the piped water & sanitation systems exceed the cost.	By child's gender: slightly higher effects for girls, particularly for intestinal infections, malnutrition, & perinatal conditions; BW effects are larger for girls than for boys, while the coefficients for length of gestation are almost identical across genders.
Rosales (2015). Effects of exposure to El Nino floods in utero and during 1st year on birth weight, height, and test scores.	1) Longitudinal HH survey on Ecuador's cash transfer program "Bono de Desarrollo Humano." 1st wave: 2003-2004; 2nd wave: 2005-2006; N~8,000 children. Sample over-represents poor families. 2) Reproductive and Health Survey (RHS): 1994, 1999. 3) Living Standards Measurement Survey (LSMS): 1995, 1998, 1999. Last two are nationally representative.	DD model: Compare regions that experienced El Nino vs. those that did not and during the years of El Nino 1998/1999 versus previous years. Model includes individual controls, village of residence FE, year of child's birth FE.	Exposure to El Nino floods (avg exp 3 mths): HAZ= -0.09 of 1SD (effects 3rd trim); PPVT= -0.13 of 1SD (effects 1st trim) LBW= +2.3pp (3rd trim) (14.6% = 0.06 of a SD).	1) By maternal educ: effects on PPVT are smaller for children w/more educated mothers (effects: - 0.02 SD). 2) By rural/urban: effects on PPVT are stronger for rural children (effects: -0.01 SD). 3) By SES index (1-2 quintiles vs. 4-5): effects on LBW significant for children in low quintiles (effects: +3.2pp).

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel E: Weather				
Shah and Millett Steinberg (2016). Rainfall shocks in rural India in utero and current on outcomes for children and young adults.	1) Survey on educational achievement of primary school children in rural India conducted every year over 5 years from 2005-2009; N=2 million children. 2) Monthly district rainfall data. 3) NSS (National Sample Survey) collected by the Government of India's in 2004-2008; includes information on wages, labor, etc.	Rainfall variation: within district & across districts within a year. Authors explore different periods of exposure: i) current shocks; ii) exposure in utero up to age 4; iii) exposure in utero up to age 16. Sibling FE models also include district FE, age FE, year of survey FE.	Children exposed to drought this year or last year: Test scores: +0.09pp (+0.07 SD = +4.1%). Years education: +0.02. Children exposed to flood: Test scores: -0.05pp (-0.037 SD = -2.3%). Test scores (exposure@11-13 & outcome@16): 0.05pp. Drought in utero to age 4: Test scores: -0.014 SD = -0.9%. Never enrolled in school: +8% (+0.01SD). Child not on track: +3pp (0.08 SD = 3.7%). Test scores (exposure in utero & outcome @age 16): +0.05pp. Years education: +0.02. Children exposed to a flood in utero to age 4: Test score: +0.03pp (0.02 SD=1.4%). Years education: -0.02.	By mother's education: effects are exclusively concentrated among children whose mother's had no schooling. By districts w/more educational expenditure: Investments in educ help mitigate the negative effect of rainfall on test scores.
Wernerfelt, Slusky, and Zeckhauser (2016). Effects of in utero exposure to sunlight (vitamin D) on childhood asthma up to age 10.	Two independent datasets: 1) NHIS: private individual-level data, aggregated by state, month, & year of birth, 1914-1987, N=260,000. NHIS data merged w/ historical weather data from the NOAA. 2) Asthma hospital discharge data from NJ & AZ, from the Health Care Utilization Project and birth records from Vital Statistics; data aggregated at the county, birth month, & year of birth, 1999-2009; N=2.1 million births (3,000 birth month by county cohorts).	Exploit the exogenous within-location variation in sunlight levels across birth years in location of birth. Assumes sunlight variation correlates w/actual exposure, but not w/ other factors affecting asthma incidence. Regressions include state of birth * month of birth FE, year of birth FE.	Doubling the amount of sunshine in an individual's location during the 2nd trim: Dataset 1) Prob(report asthma diagnosed): -1.15pp (-10%) (no standard deviations provided). Dataset 2) Rate of asthma emergency department discharges: -2.21pp (-21.3%) (no standard deviations provided). No effects in 1st or 3rd trimester in either data set.	NA

Table 1: Effects of Mild Early Life Shocks on Future Outcomes

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel F: Alcohol and Tobacco Policy				
Barreca and Page (2015). Focus on effects of changes in minimum legal drinking age in state and year of birth, 1978-1988.	1) Birth outcomes from the National Center for Health Statistics (NCHS) files (1968–1989), N= 73,973. 2) Month-year MDLA data from Distilled Spirits Council of the U.S. Datasets matched by mother’s estimated age at conception, month of conception, & mother’s state of residence at delivery.	DDD approach: exploiting variation in MLDA laws that occurred across states in 1970s-1980s. Comparing birth outcomes btw: Treatment: infants of mother’s 14–20 years old and Control group: infants born to mothers 21-24 years old. Models include state of birth, month, & year of birth FE, & age-by-year FE & state-by-age FE.	Children of mothers 18-20 years old exposed to the MLDA of 18 years experience: LBW: -0.10pp (-1.2%) (Table 1 does not include SD!) Female child: +0.18pp (+0.4%) No effects on Apgar, preterm birth, congenital defects.	By race - A MLDA of 18 years: Whites: LBW: small increase Sex ratio: no effects Blacks’ fetuses are positively selected: Preterm: -0.3pp Sex ratio: +0.462pp.
Bharadwaj, Johnsen, and Løken (2014). Effects of a smoking ban in restaurants/stores in Norway on health at birth.	1) Birth records for all Norwegian births, 1967 to 2010, includes unique identifiers , & smoking behavior at the start and end of pregnancy. 2) Longitudinal administrative records: 1967-2010 (includes gender, DOB, city, marital status, years of education, LFP, earnings, occupation). N=4,030.	Exploit a smoking ban in Norway as a natural experiment. Authors are able to identify mothers who worked in restaurants & bars during the period of interest. DD: by compares outcomes before & after the law change for people working in restaurants & bars to the same difference among people who work in a similar occupations. Also estimate twin FE models.	Mothers who benefited while pregnant: VLBW: -1.8pp (-0.6pp controlling for gestational age = -26% = -0.04 SD). Pre-term: -2.5pp (-39% = -0.10 of a SD). Twin FE: children born after the reform have better health outcomes. BW: +175gr (most of the effects come from the lower tails of the BW distribution). VLBW: -5.8pp . A 100 g increase in BW increases adult income at 28 by 1.7%, & income conditional on full time employment by 0.7%.	Effects of the reform: stronger for mothers who reported smoking at start of pregnancy. BW: +160 gr (mothers who smoked at the start of preg; effect is concentrated at the lower tails of the BW distribution); no effect on non-smoking mothers.
Nilsson (2015). The effect of alcohol consumption during pregnancy on long-term outcomes of the first and second generation.	1) LOUISE database covering all individuals of ages 16 to 65, living or working in Sweden 1990- 2004; includes year & month of birth, gender & region of birth, education, labor market outcomes, welfare payments. Individuals linked to biological parents using the “multi-generational” register. N=4,104 obs. 2) Military enlistment data on cognitive & non-cognitive outcomes for 18 year old males.	Exploit an alcohol policy in Sweeden in the late 1960s that temporarily and sharply increased access to strong beer in certain regions and among young people. DDD: compare the cohort that was exposed to the policy change in-utero to cohorts exposed at other moments in their life exploiting variation in: i) year and month-of-birth, ii) region of birth, iii) age of the mother (below above age 21). Models include mother FE.	Children born to mothers under the age of 21 at delivery, in the treatment regions, and conceived between July and October 1967: Earnings: -24% Prob(no earnings): +56% (+7.2pp). Prob(welfare recipient): +56% (+3.5pp). Prob(low cognitive ability): +27%. Prob(low non-cognitive ability): +16%. Years of schooling: -0.3 (-2.6%) . Effects on the next generation: Health at birth outcomes: no effects on prematurely born, LBW, sex ratio.	Effects of the policy: Earnings: -24% (men only). Prob(no earnings): +74% (+8.3pp) (men only). Prob(welfare recipient): +79% (+4.5pp) (men); +40% (+2.7pp) (women). _Years of schooling: -0.5 (-4.3%) (men); -0.2 (-1.7%) (women). Males more likely to be premature or miscarried. Share of males: -7.3pp Gestation length: -1 week (-0.28 months) (boys only).
Simon (2016). Changes in maternal smoking due to tax changes and health of U.S. 3-17 year olds.	1) NHIS - restricted-use geocoded data, 1997-2010; N=118,271. 2) Vital statistics, 1989–2004, N~2million.	Exploit variation in cigarette taxes btw 1989-2007 at the state and municipal levels. DD: identified off by variation in the timing & size of changes in taxes across states & over cohorts. Models include state and year-month FE, demographic and state policy controls, and linear time trends.	A \$1 dollar increase (in \$2009) in state cigarette excise tax: Sick days from school: -10% (no SD available on outcomes). 2 or > doctor visits in past year: -4.5%. Hospitalizations: -19%. Asthma attacks: -16%.	Effects are twice as big on less educated mothers. Effects are significant for teen mothers but no effects for children of older moms.

Table 2: Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Adhvaryu and Nyshadham (2016). Impact of iodine supplementation in Tanzania on parental investments on children 0-5.	DHS 1999; representative of women of reproductive age. N =456 children 0-5 (and their mothers).	Exploit the variation in in-utero exposure to a large-scale iodine supplementation program across districts. Linear Prob. Models include rich controls & district & child's age FE. To test for resource allocation spillovers across sibling, authors regress health investments on own and sibs' accumulated treatment.	A 1 SD increase in treatment exposure: Vaccination: +0.2 of a SD (polio 0.16pp, measles 4.5pp). Breastfeeding >=6mths: +0.1 of a SD (3.5pp) (parents reinforce investments). Siblings of treated children were more likely to be immunized (no effects on breastfeeding.)	Vaccinations highly responsive to parental observed benefits from the program... even when treated child is younger/older, younger/older siblings are more likely to receive additional investments (i.e.vaccination.)
Baker and Milligan (2016). Ask how differences in parental time investments are related to gender gaps in reading and math scores in Canada, the U.S., and the U.K. at school entry.	1) Canada: National Longitudinal Survey of Children and Youth (NLSCY); children born btw 1999-2004; 2) US: Early Childhood Longitudinal Survey-Birth Cohort (ECLS-B); children born in 2001; 3) UK: Millennium Cohort Study (MCS); children born in 2000/2001; N=was not reported. 4) US data from: i) American Time Use Survey (ATUS); waves 2003-2011; ii) National Survey of Family Growth (NSFG); waves: 2002 & 2006-08; and Canadian data from the Maternity Experiences Survey (MES).	Authors assume sex of 1st born child is exogenous. Model regressions include demographic + SES controls and a dummy variable for first born male child. The authors investigate how parental investments change with child's age Twin FE: authors test the hypothesis that parents treat opposite sex twins with greater similarity than parents generally treat sons and daughters (time inputs were asked separately for each twin in the UK data).	Controlling for parental time inputs in early life (ages 0-3) in baseline regressions reduces: Gender gap (boy/girl) in reading scores: -23% in US, -16% in UK, -33% in Canada. Gender gap in Math scores: -25% in US, -23% in U.K., and -33% in Canada.	Boys have lower reading and math scores at school entry. Authors argue that this may be explained by parental time inputs.

Table 2: Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Bharadwaj and Lakdawala (2013). Investigate gender differences in prenatal care, neonatal and early childhood mortality among mothers who had an ultrasound in India, Bangladesh, and China.	<p>1) India: National Fertility and Health Survey (NFHS), waves: 1998–1999, 2005–2006.</p> <p>2) Bangladesh: Demography & Health Survey (DHS), waves: 1996–1997, 1999–2000, 2004, 2007.</p> <p>3) China: Health and Nutrition Survey (CHNS), waves: 1991, 1993, 1997, 2000, 2004, 2006.</p> <p>Authors also use DHS data for other countries: Pakistan (2006–2007), Ghana (1993, 1998, 2003, 2008), Sri Lanka (1987), & Thailand (1987). N=32,012.</p>	<p>Exploit the fact that some mothers had ultrasounds (so could discriminate prenatally) while others did not. If mother did not have ultrasound can only discriminate post-natally. Also expect larger effects in places where sex discrimination is more severe (e.g. Northern India). Models (linear & logit) include a dummy for gender of fetus, mother/child controls (that includes birth order, fam size, etc.), state FE & year of birth FE</p>	<p>Mother pregnant with a boy: Attended prenatal care at least twice per week (India): +1.8pp (3%) (+4.6% in Northern India where sex discrimination is higher)</p> <p>Tetanus: +3% (only sign. for Northern India).</p> <p>Results are only significant in the sample of mothers who had an ultrasound.</p> <p>No evidence of sex-selective prenatal care in countries with weak or no son preference (i.e., Ghana, Sri Lanka).</p> <p>Tetanus shots can explain 2.6–7.2% of the excess female neonatal mortality.</p>	Larger effects in northern India.
Breining, Daysal, Simonsen, and Trandafir (2015). Spillover effects of medical treatments received by VLBW children on their siblings.	<p>1) Birth register data from Denmark since 1970.</p> <p>2) Emergency room visits data (available between 1995 and 2011), provides inpatient hospital admissions & mortality.</p> <p>3) Data on academic achievement including 9th grade test scores (available from 2002), high school enrollment by age 19.</p> <p>Final sample = 3,677 obs.</p>	<p>RD that exploits changes in medical treatment around the VLBW threshold (as in Almond et al., 2010).</p> <p>Treatment group: siblings of a child with BW just below 1,500 grams & with 32 or more weeks of gestation</p> <p>Control group: siblings of a child with BW just above 1,500 grams & with 32 or more weeks of gestation.</p>	<p>A child with a VLBW sibling (with 32 weeks or more gestational length) who received medical treatment due to this condition, experiences:</p> <p>Math test score (@age 15): +0.36 SD</p> <p>Language test score (@age 15): +0.31 SD</p> <p>High school enrollment (@age 15): +9.5pp (+30%)</p> <p>Mortality (28-day & 1-year mortality) (ages 0-15): no effect</p> <p>Diagnosis of intellectual disability <age 5: no effect.</p>	Heterogeneity in the spillover effects on sibling academic achievement varies by sibship characteristics that are most closely tied to the quality of peer interactions (gender of sibling, gender composition of the sibling pair, and birth order).

Table 2: Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Del Bono, Ermisch, Francescon (2012). Ask how smoking and maternal work stoppage before birth affect outcomes in the U.S. and U.K., and whether parents respond to idiosyncratic changes in one child's endowments by altering investments in a later child.	Three large representative samples: 1) UK: British Household Panel Survey, longitudinal, 1991–2005, N=1,339 singletons 2) UK: Millennium Cohort Study, longitudinal, years of birth: 2000 & 2001, N=17,483 singletons 3) US: National Survey of Family Growth, authors use the 5th cycle (1995), data is retrospective on children who were born in 1970-1995, N=12,166 singletons.	To address endogeneity of choice of birth inputs, use method of moments estimator (similar to an IV-FE that uses prenatal inputs during earlier pregnancies as instruments for differences in inputs between pregnancies). Identification assumption is that prenatal inputs associated with a specific pregnancy are uncorrelated w/the idiosyncratic child endowments. Authors estimate the direct effect of inputs on birth outcomes (structural parameters) & the reduced form parental responses to realized child endowments when choosing the inputs in successive pregnancies.	1) Maternal smoking during preg: BW: -190 to -200 grams (-5.6% = -0.34 of a SD) (BHPS & MCS datasets); -139 grams (NSFG) (-4.2% = -0.24 of a SD). Fetal growth: -5.4% (-0.36 of a SD) (BHPS); -4.1% (-0.26 of a SD) (NSFG). 2) 3 month-work stoppage in late preg: BW: 5.2% (0.3 of a SD)(BHPS); 1.8% (0.10 of a SD) (NSFG). Fetal growth: 3.5% (0.23 of a SD) (BHPS); 1.3% (0.08 of a SD) (NSFG). "Parents respond to idiosyncratic endowment heterogeneity in a way that is easier to reconcile with inequity aversion."	More educated women are less likely to smoke and more likely to stop working three months before birth during their first three pregnancies.

Table 2: Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Dizon-Ross (2014). Investigate the effect of providing parents with information about their children's true achievement on parental investments.	1) Author conducted a sibling census during January - March of 2012, based on information on children participating in 39 schools in two districts in central Malawi (the Machinga and Balaka districts) 2) Test data were gathered for all periodic exams administered at school N=3,464 households with at least 2 children enrolled in grades 2-6	Randomly assigned half of the households to a treatment group that received information about their children's recent achievement test results in school, and half to a control group, which did not receive information	The information delivered to parents about their children's academic abilities: (1) Parents' perceptions of their children's achievement diverges from children's true achievement: the gap is 1 SD. (2) Parents reallocate educational investments: Willingness-to-pay for remedial math and English textbooks: +1.3pp in subjects in which children were doing worse than expected. Free subject-specific workbooks (remedial, average, advanced): parents shifted their choices towards workbooks that corresponded more closely to their children's true achievement level.	Poorer, less-educated parents have less accurate perceptions about their children's academic abilities than richer, more-educated parents, and update their beliefs more in response to improved information.
Cunha, Elo, and Culhane (2015). What would happen to investments & child development if a policy that moved expectations from the median to objective estimates from the CNLSY/79 data was implemented?	1) Children of the National Longitudinal Survey of Youth/1979 (CNLSY/79); authors employ the Motor-Social Development Scale; N=335 African American mothers.	Formulate a model of early childhood development in which mothers have subjective expectations about the tech. of skill formation. Empirically, the identification of the model poses a problem: preferences and beliefs are confounded. To solve this problem, authors create a survey instrument to elicit maternal expectations about the tech. of skill formation. Mothers are asked: "what is the youngest and oldest age at which your baby will learn how to do task X or Y?" (the tasks are taken from the Motor-Social Development Scale of the CNLSY/79 and NHANES). Authors exploit within-family variation to estimate the parameters of the technology of skill formation.	1) Mothers underestimate the elasticity of child development w.r.t. investments: Mothers' subjective expectation about the elasticity of their child development w.r.t. investments is btw 4-19%, but authors estimate indicates elasticities btw 21-36%. 2) A policy that moved expectations from the median to objective estimates would increase investment by 4% to 24% and stocks of cognitive skills 24 months would increase by 1% to 5%. The impacts of such a policy would be even higher for mothers whose expectations were < the median.	NA

Table 2: Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Fryer, Levitt, and List (2015). Effect of parental incentives on early childhood cognitive and non-cognitive achievement.	Longitudinal data collected for the study includes pre-test characteristics of the sample of children & families (year of data collection is 2011), children's test scores in the middle of the treatment year (January 2012) & at the end of treatment (May 2012) N= 260 families.	Randomized field experiment. Families were randomly assigned to 3 groups: 1: parents paid in cash or via direct deposits for attendance at early-childhood sessions; N=74; Treatment 2: parents paid for attendance in early-childhood program attendance via deposits into a trust which can only be accessed when the child enrolls in college; N=84; Control group: parents not paid & did not attend early-childhood sessions; N=99.	Children of parents who participate in the intervention: Cognitive (PPVT; Woodcock Johnson III Test of Achievement scores): no effect. Non-cognitive (Blair and Willoughby Executive Function scores, Preschool Self-Regulation Assessment score): +0.23 SD.	Positive effects only among whites and Hispanics (little impact on Black children). Students who started below the median non-cognitive skills, experienced no benefits in cognitive or non-cognitive outcomes, while those who started with above the median non-cognitive skills, experienced increases on both cognitive & non-cognitive skills.
Hsin (2012). Ask whether maternal time investments from 0-12 compensate or reinforce birth weight differences and whether effects differ by SES.	1) Time diaries from the PSID-CDS; time diaries are child-specific, the PSID collected time diaries & child info for up to two randomly selected children within each family; time-diaries sample weekdays & weekends for 24 hours; N1,516 children, or 758 sibling pairs.	Sibling FE estimates of the effect of birth endowments on parental investments & include interactions between child endowment & characteristics such as mother's education or family income Models include rich controls, interactions between birth endowments*SES, and splines to measure family SES.	Overall effect of birth endowments on parental time investments & the interaction between BW*mother's characteristics: Total hours per week: no effect Hours devoted to activities that develop the child's human capital (reading, playing, doing hobbies, etc): no effect.	By mother's educ: College educated mothers compensate by investing more in LBW children: children receive +0.65 SD (total time), +1 SD (educational time). Mothers with <=12 years of education concentrate resources on higher BW children: non-LBW children receive +0.17 SD total time & -0.10SD educational time than LBW siblings.

Table 2: Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Yi, Heckman, Zhang, and Conti (2014). Asks how Chinese parents alter investments in twins at ages 6-18 in response to the serious illness of one twin at age 0-3.	Chinese Child Twins Survey (CCTS); includes detailed info on family health & educ investments for e/child; conducted in 2002 to 2003 in the province of Kunming, China; N=1,694 households with twins.	Early health shocks affect children both biologically and by affecting parental responses. Assume that "the within-twin variation in early health shocks is random and exogenous." To estimate effects of health shocks on child's outcomes and address the possibility that family investments may be endogenous, authors use an IV based on within-twin variations in BW, gender and HH level variables (rural indicator, maternal working sector, age, ethnicity, and schooling).	When a twin child suffered from a serious disease at ages 0-3: Parental investments: Health investments in the sick twin (\$ spent on medical treatment, medicine, health products): + RMB 305 (+\$49 US) (+35% = +0.39 SD). Educational investments in the sick twin (tuition + \$ spent on books, stationery, home tutors, tutoring class): RMD -182 (-\$30 US) (-20% = -0.15 SD). Child outcome results suggest that parental investments equalize health but increase disparities in education in favor of the healthier twin.	Rural areas: Increase in health expenditures in favor of the sick twin is not accompanied by a decrease in educational expenditures. Urban areas: the fall in educational expenditures on the sick child offsets the cost of medical expenses. Compensating investments and reinforcing educational investments are more precisely determined among high education mothers and in female twins. Wealthier households have more reinforcing educational investments.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Adhvaryu, Fenske, and Nyshadham (2016). Effects of cocoa price shocks in Ghana in year of birth on mental and physical adult health.	1) Cocoa prices time series. 2) EGC-ISSER Socioeconomic Panel; baseline data on cocoa production Nov. 2009 to April 2010; plots of land & type of crops, 10 regions; data also includes Kessler Psychological Distress scale-10 questions. N= 7,741 individuals. 3) Demographic and Health Survey; waves: 1988, 1993, 1998, 2003, 2008; nationally representative cross-sections women 15-49.	HH's in the cocoa-producing regions of Ghana experience changes in the real producer price of cocoa as income shocks, while HH's in regions that do not produce cocoa are unaffected by these fluctuations. Linear models include region r and year of birth t FE and individual and HH controls; some specifications include region linear & quadratic time trends, rainfall & temperature controls, as well as household FE.	A 1 SD rise in the cocoa price in the year of birth: Kessler Psychological Distress scale: -2pp (-0.08 SD; -1.0%). Severe distress (Kessler scale>10): -3pp (-0.13 SD; -4.5%). Physical health: Height: +1.23cm (no avg. height provided in descriptive stats) BMI, savings, occupation: no effect.	By gender: very mild differences across males and females. By timing of exposure: Shocks in the first 4 years of life have significant effects, though effects are largest in the YOB.
Almond, Hoynes, and Schazzenbach (2011). Effects of introduction of the U.S. Food Stamp Program on birth weight and fertility.	Vital statistics - Natality & death records 1959-1977; N~2M observations per year. SEER population data (to construct fertility rates).	Use the county-by-county rollout of the FSP. Model regressions include county level controls, county and year of birth FE, state*year FE, interactions of pretreatment county characteristics with time trends. Event time study: Authors do not have information about FS participation or data to impute eligibility (e.g., income). So they use the 1980 CPS to calculate FSP participation rates for women with a child <5.	Food stamps during pregnancy increase BW by: Whites +2.04 gr (effect size= 0.06%) Blacks +3.45gr (e.s. =0.08%). Estimate of TOT effect (after adjusting by participation rate) on BW: Whites: +15 to 20gr (effect size: 0.5-0.6%) Blacks: +13 to 42 gr (0.4-1.4%). No statistically significant effects on fertility or neonatal mortality.	Largest impacts at lower BWs. LBW: -7% for whites, -5% to -11% for blacks. Poor counties face +3.41g BW, no effect in wealthier counties. Larger effects in the South and in urban counties. Larger impacts for older mothers. Black single mothers experienced larger impacts than all black women.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Aizer, Eli, Ferrie, and Lleras-Muney (2016). Examines the long run effects of the US Mother's Pension Program on child survival by comparing mothers who were accepted and those who were rejected from the program.	1) Individual-level administrative records of applicants to the Mothers' Pension program: N=16,000 children from 11 states who were born 1900-1925. 2) WWII enlistment records. 3) 1940 census records. 4) Social Security Death Master File (DMF); name, date of birth, date of death, SSN for 88 million deaths reported from 1965-2012. Authors matched administrative data to census, WWII, & death records. Able to match 48% of sample to a unique death record. Females could not be matched due to name changes.	Compare children of mothers who applied to the MP transfers & were given the receipt, to the children of mothers who applied for transfers but were denied. Rejected mothers were on average slightly better-off based on observable characteristics. Hence, the effects of the program are likely to understate the benefits of the program. Models include state-level, time-varying characteristics (i.e., ratio of state manufacturing earnings to national manufacturing earnings, laws governing school attendance, expenditures on social programs, education & charitable institutions, hospitals & prisons); county-level characteristics in 1910, county & cohort FE.	Effect of access to the Mother's Pension program: Longevity: +1.5 years (+2.1%) (no standard deviations provided in descriptives). Prob(of survival past age 70): +10-20%. Prob(of survival past age 80): 9-15%.	Effects are driven by the poorest families in the sample.
Akee, Simeonova, Costello, et al (2015). The effect of a permanent increase in unearned household income on children's emotional, behavioral, health, and personality traits.	The "Great Smoky Mountains Study of Youth": longitudinal survey of 1,420 children aged 9, 11, 13 years at the survey intake, who were recruited from 11 counties in western NC; follow-ups occur annually until ages 16, 19, 21 N=6,050 children.	A casino opened on the Eastern Cherokee reservation and part of profits were distributed per capita to all adult tribal members (Transfer=\$4,000 annually; amount comparable to TANF or SNAP). DD: Compare outcomes for adolescents who resided in households with extra income (youngest and middle age cohorts of American Indian children) to adolescents who were not exposed to the extra income by age 16 (the oldest age cohort). Models include individual FE, age FE, age*race FE	Child resides in a household that receives the unearned income transfers due to the casino revenues: Behavioral disorders: -0.27 SD Emotional disorders: -0.36 SD Personality traits: Conscientiousness: -0.43 SD Agreeableness: -0.31 SD Neuroticism: no effect	Income transfer improved child outcomes through better parent-child relationsp and not necessarily through more parental time investments "parents who receive the \$ provide investments in their childrenwith lower than avg. personality traits and lower than avg. amounts of behavioral and emotional problems" (i.e., compensatory responses)

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Barham, Macours, and Maluccio (2013). Examine the effect of Conditional Cash Transfers received in utero to age 2 vs. ages 2-5 in Nicaragua on cognitive and health outcomes.	1) Household data from the phase -in & follow-up of the randomized CCT experiment; years 2000 & 2010; N= 171 boys in the "early treatment" group + N= 197 boys in the "late treatment group" born up to 1 year after CCT started (Oct, 2001).	42 localities in 6 municipalities were randomized into early-treatment (21) vs. late treatment (21); groups were stratified by their poverty level Treatment group - "early-treatment" boys were exposed to the program from in-utero to age 2. Control group "late treatment" boys were exposed from ages 2 to 5. Models include birth month FE, stratification dummies to account for the stratification in the randomization (i.e., poverty).	Boys exposed to the program in utero up NA to age 2 vs. ages 2-5: Cognitive outcomes: +0.15 SD Anthropometrics: no effect.	
Bharadwaj, Lundborg, and Rooth (2014). Explore whether low birth weight affects how one is affected during economic downturns.	1) Swedish registry data on births: data on all twins born in 1929-1956; N=5,000 twins. 2) UREG: data on individual years of schooling, 1990-2007. 3) Income data: equivalent of W2 records in the US, 1981-2005. 4) Statistics Sweden: provides info on occupation for 1985 and 1990.	Compare cohorts who were born years before the economic crisis (1985-1990) with cohorts born few years after the crisis (1993-1998); Include twin FE. Assumptions: Post-birth investments within twin pairs are not correlated to birth weight.	A 10% increase in BW: Receives unemployment insurance: -1% (no SD available) Years receiving UI: -0.4 years (-80%) "a 10% increase in BW (approx. 260 grams) results in a 0.008pp lower prob of being on unemp insurance."	One potential mechanism driving the effects is "occupational sorting in the pre- crisis years". Affected cohorts were less likely to be employed in the public sector and less likely to enter a white collar job.
Black, Devereux, Løken, and Salvanes (2014). Effect of a 1 year childcare subsidy at age 5 on parental behavior and teen GPA.	1) Administ. data covering the entire population of Norway, cohorts: 1986-1992; authors link individuals to their parents through unique identifiers. N=367,836 obs. 2) Municipality-level data on childcare prices and family income cutoffs in the 1990s.	Exploit sharp discontinuities in the price of childcare (CC) by income. Compare outcomes of children whose HH income was just less than a cutoff to those of children whose HH income was just above a cutoff. Also estimate a parametric specification that controls for indiv/HH charact & cohort by municipality FE, as well as sibling FE.	Being eligible for lower CC prices at age 5: No change in use of child care, so subsidy only increased income. GPA: +0.30 of a SD Oral exam grade: +0.30 of a SD Main result: A 1% increase in family income at age 5: would increase scores by about 0.04 of a SD Sibling FE: similar by less precise.	NA

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Chetty, Hendren, and Katz (2015). Examine two hypotheses: 1) moving to a lower-poverty neighborhood improves LT outc. for children who moved young? 2) the gains decline with child's age at move?	1) Moving to Opportunity data includes demographic, SES, school data, criminal victimization, income, transfer receipt; There are 11,276 children in the MTO data, of whom 8,603 (76%) were born <= 1991. ii) annual data on residential neighborhood (census tract) using 1990 & 2000 Censuses; 2005-2009 American Community Surveys. 2) Federal income tax returns data, 1996-2012. *MTO records were linked to the tax data by SSN (86% success).	Experiment: families were randomly assigned to 3 groups. 1) Experimental grp: was offered subsidized housing voucher + requirement to move to a census tract w/poverty rate <10%. 2) Section 8 voucher grp: was offered a standard subsidized housing voucher w/no additional contingencies. 3) Control grp: was not offered a voucher (but retained access to public housing). *Authors replicate ITT models as in Kling et al. (2007). Models also include interactions of age at RA * treatment indicators.	Effects on children <age 13: 1) Voucher (experimental) group Income: \$1,624 (+14%). Attends college: +2.5pp (+15%) Prob(live in a poor neighborhood as an adult): -4% Prob(single parent): -15% (only for females) 2) Section 8 Income: no effect. Attends college: no effect Prob(live in a poor neighborhood as an adult): -7% Prob(single parent): no effect Effects on children >=age 13 Little (or sometimes negative) effects on older children.	Gains from moving to lower-poverty areas decline with child's age at move. The extra federal income taxes that young children in the experimental group would obtain during their mid-twenties, would offset the incremental cost of providing voucher treatment relative to providing public housing
Dahl and Lochner (2012). Effects of changes in U.S. Earned Income Tax Credit on child test scores, mean age=11 at testing.	1) Child Supplements of the NLSY, longitudinal data, N=4,500 children. Includes PIAT scores for children 5+ from 1988 to 2000 (biannually). (Children took each individual test at most 5 times.) N= 4,412 children born to 2,401 mothers.	Identification comes primarily from the substantial expansion of the EITC schedule between 1993 and 1995. Child FE + IV (instrument for HH income: predicted EITC income due to regulatory changes & not due to changes in family structure). Models include year FE, controls for other state-level policies, a fifth-order polynomial in lagged pretax income & an indicator for positive lagged pretax income as a baseline "control function", national trends.	A \$1,000 increase in income: PIAT score (combined math & reading test scores): +0.06 SD. Reading recognition: +0.04 SD. Reading comprehension: +0.06 SD. Math: 0.06 SD. 1st stage coefficient: 1.270** Overall effect: from 1987–1999, the median EITC payment for eligible two-child families increased by \$1,670 (2000 dollars), implying a test score increase of 0.010 of a SD for this group.	Test gains are larger for children from disadvantaged families (minorities: +0.08 SD, children in unmarried families: +0.08 SD, children of mothers with HS or less educ: +0.05 SD), for younger children (ages<12 the effect is: +0.08 SD), and for boys (+0.09 SD).

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Del Boca, Flinn, and Wiswall (2013). Asks how cash transfers affect parental investments in children in the U.S.	1) Longitudinal data from Child Development Supplement of the PSID; first 2 waves (CDS-I & CD-II) 1997 & 2002-3, include child time diaries & rich demographic and SES HH data, N= 3,500 children residing in 2,400 HH (authors also use the PSID waves 1997, 1999, 2001, 2003).	Authors estimate the parameters of a production function for child outputs using a Cobb-Douglas production function & simulation methods (using PSID-CDS data).	Estimates suggest that parental time inputs are more valuable than monetary inputs in producing child quality. Time is relatively most valuable when children are young. Suggests that monetary transfers may have small impacts on child quality because a significant fraction of the transfer is spent on other HH consumption and the leisure of the parents.	NA
Hoynes, Miller, and Simon (2012). Effects of changes in U.S. Earned Income Tax Credit on incidence of low birth weight.	1) Vital Statistics micro data, 1984-1999, collapsed to cells defined by state, month-year, parity of birth, mother's education, marital status, race, age; N=47,687 cells. 2) March Current Population Survey combined with the NBER TAXSIM model to compute average EITC benefits.	Exploit tax-reform (1986, 1990, 1993) induced variation in the federal EITC across time & family size. 1) DD: Compare 2nd & higher order births (treatment) to 1st births (control). Models include effective tax year FE, state FE, & rich demographic controls. 2) Event study. 3) Panel FE model to measure the generosity of the EITC using the maximum EITC credit.	2nd parity or higher births, relative to 1st births: LBW: -3.5% for the full sample (no SD available) (effects are larger for 3rd or higher order births than 2nd births). An increase of \$1000 treatment on the treated (TOT): LBW: -6.7%.	LBW: larger effects (-10.8%) for infants of single and less educated mothers. By race: African American infants largest reduction in LBW (-5.1% vs. whites -1.6%). Effects on Hispanics are small (-1.9%).
Hoynes, Schazzenbach, and Almond (2016). Effect of exposure to the U.S. Food Stamp Program (FSP) from 0-5 years on adult health (age 25 plus).	Panel Study of Income Dynamics (PSID); 3,000 HHs; use waves until 2009. The "Survey of Economic Opportunity subsample"; N=1,900 low-income & minority HHs selected from an existing sample (adjust for nonrandom sample using PSID weights).	DD model: Exploit variation in roll-out of FSP across counties & over birth cohorts in exposure to the FSP. DDD: use variation across subgroups w/varying propensities to use FSP. Models include controls for county, year of birth, interview FE, state linear time trends, county-yr of birth controls.	Increasing the share from no FSP exposure to full exposure in utero to age 5): Metabolic syndrome Z-score (obesity, high blood pressure, diabetes, heart attack): -0.3 SD (TOT: -0.24 SD) (largest effects on males 0.5 SD). Weak improvements in other health outcomes: diabetes, health status, disability, smoking. Gains from FSP are large and increasing with exposure up to age 5.	Largest effects on males: 0.5 of a SD. Economic self-sufficiency: +0.3 of a SD for women only. Adult health impacts of FSP are minimal if child is exposed only after age 5.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Gould, Lavy, and Paserman (2011). Effects of material resources such as running water, electricity, and sanitation during childhood on outcomes at age 56-61 of Yemenite immigrants to Isreal.	1) Authors conducted a survey in 2006 of the entire population of immigrants who were born in Yemen between 1945 and 1950 and arrived in Israel during 1949 and 1950. N= 2,927 individuals who were sorted into 233 different locations. 2) Census data for 1961.	Authors exploit quasi-random variation in the living conditions experienced by Yemenite children after being airlifted to Israel in 1949. Models regress a person's outcome on the conditions experienced in childhood and on family/individ background.	Running water, sanitation, and electricity in early childhood - Results for girls and women only: HS matriculation: +9pp (+33%) (no SD provided). Post-secondary: +6pp (4.7%). Years of schooling: +0.6 (5.3%). Age at 1st marriage: +0.6pp (2.7%). Fertility (N_children): -0.2pp (-5%). Employed: +7.2pp (11.3%). Self-reported health problems: -6.2pp (-15.5%). No effect on disability. 2nd generation effects in the full sample: HS matriculation: 3.2pp; College degree: 3.3pp (baseline means not provided).	By gender: Effects are mainly for women which could be due to: i) gender discrimination in the allocation of scarce resources or ii) a stricter enforcement of traditional norms in rural areas. By age: Authors include an interaction between treatment variables and YOB & find that older women experience much larger impacts (results not shown).
Lindo (2011). Health effects of parental job displacement on child's birth weight.	1) PSID; waves: 1968– 1997 (author stops in 1997 due to concerns in how job displacement is measured). Author uses the PSID's Childbirth & Adoption History Supp. (CAHS) to measure children's outcomes i.e., birth weight in ounces is available for children born in 1985+; N= 1,607 births.	Compare the outcomes of children born after a displacement to the outcomes of those born before. Mother FE. Models also include education-group trends and industry trends.	Child was born after his/her father's job displacement: Birth weight: -4.8% (approx. 5 ounces decline).	Mother's with >HS have higher percent declines in family income, are more likely to work, and to work for more hours. Potential mechanisms: Husbands' earnings: -22% Family income: -13%. Men's work activity: no change. Mother's employment status: no change. Food spending: no change.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Carlson (2015). Examine the direct consequences of job loss on birth outcomes, isolating anticipatory effects.	1) Dates of major job losses & information on the warnings given to the local community using notices filed under the Worker Adjustment & Retraining Notification (WARN) Act. 2) Natality data, 1999-2008. *The author constructs a county-month panel data set including all 422 counties in AL, NY, TX, & WA; N=7,113,083 births & 2,626 WARN notices.	Exploit county-month variation in the occurrence of job losses through announced notices Models include county-specific quadratic time trends, county of birth, year of birth, & calendar month of birth FE.	Being exposed to anticipatory dislocations during pregnancy: Birth weight: -15 to -20 grams (-0.4% to -0.06%). Gestational age: -0.5 to -0.8 days (-0.2% to -0.3%). LBW= +1pp (+16.4%) Strongest effects are associated with exposure to notices in 3rd trimester.	Potential mechanisms: physiological stress responses or increased levels of unhealthful behavior.
Golberstein, Gonzales, and Meara (2016). Effects of economic recessions (measured by UR and HPI) on child and adolescent mental health.	1) National Health Interview Survey (NHIS), years 2001-2013; nat. The child's mental health questionnaire (SDQ score) has 5 domains: emotional symptoms, conduct pb's, hyperactivity-inattention, peer problems, prosocial behaviour. Mental health treatment & medication use are only available for 2005-2007. 2) Economic variables are obtained from the BLS & from the Freddie Mac Housing Price Index (HPI).	Exploit the state and quarter variation in the unemployment rate (UR). Models include state & quarter FE, individual and family covariates, & state linear time trends.	A 1SD increase in the UR: SDQ score (index of mental health severity; higher index, worse mental health): +2.3% in the "mental health severity 1/10 scale" and +11% in the "likely psychological problem". Emotional difficulty score: +4.8% in the "mental health severity 1/10 scale" and +10.4% in the "likely psychological problem". Use of special education services for children's emotional problems: +5.7%.	Parental unemployment, reduced family income & higher family stress are likely to influence child mental health. The impacts were stronger among households where parents have < college, are non-white, or are in the bottom income quintiles. Authors also find little differences by child's gender or by child's age (comparing children vs. adolescents).

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Gutierrez (2014). Effect of birth during economic crisis in Peru on infant mortality, education and employment at 15-18 years.	1) National Household Survey (Encuesta Nacional de Hogares, ENAHO), 8 waves: 2004-2011; data on educational & health outcomes at later ages; N=39,846 children. 2) DHS data, 3 waves: 1991, 1996 & 2000; data on mother's health & child's mortality; N=11,275 children.	Estimate a two-sample instrumental variable model: 1) Regress child mortality in 1st year of life on dummy for YOB interacted by mom's education. 2) Regress outcome @age 15 on dummy for YOB interacted by mom's education. 3) Ratio of coefficients of interest in 1) & 2) shows the effect of early-life health shocks on future outcomes. Models include rich controls and some specifications include trends.	Exposure to the crisis and being born to less educated mothers: Prob(dying in the 1st year of life): 1% (no Table 1 available). Chronic illness: +2.36pp (no Table 1 available). Complete primary education (ages 15-18): -1.7pp. Employment (ages 15-18): no effects. Calculates upper and lower bounds on the effects by assuming: i) there is no selection; ii) there is no scarring effect.	Mother's education: the increase in infant mortality during the crisis was particularly severe for children born to less educated mothers.
Lavy, Schlosser, and Shany (2016). Children conceived in Ethiopia and born in Isreal after their parents migrated. Effects of early childhood conditions on outcomes at 18-20.	1) High school administrative data linked to demographic records for all Ethiopian children born 1992-1992; data include student's birth date, date of immigration, country of origin of students & parents, student demographics (parental education and number of siblings), current schooling status; data collected in 2007-2011; N=1,951 students.	Exploit the timing of the immigration shock of Ethiopian jews to Israel in the May 1991. DD: 3 groups by the gestational age at the time of the immigration: 1) Children whose mothers arrived after conception but before week 8 of gestation. 2) Children whose mothers arrived at 8-24 weeks of gestation; 3) Children whose mothers arrived after week 25 of gestation but before birth. Models include cohort & month of birth FE and rich controls.	Exposure to Israel's better conditions before week 8 of gestation: Matriculation diploma: 12.2% (0.07 SD). Quality of matriculation diploma (more challenging study programs during high school): +33% (0.39 SD). Math credits: +39.6% (0.32 SD). English credits: +33% (0.37 SD). No effect on high school completion. All effects are driven by exposure in the first 8 weeks of gestation (i.e., no effect of exposure after week 8).	By gender: Effects are only significant among girls. By parental education: Effects are stronger for children from families with higher parental education. (Though most immigrants had low levels of education.)

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Loken, Mogstad, and Wiswall (2012). Effects of Norwegian oil boom on family income and child outcomes at 29 plus.	Administrative registers for the entire population, provide information on educational attainment, IQ, & family income during childhood, 1967-2006; control variables: sex, birth year, marital status, N of children, SES (years of education, IQ, income, etc), personal identifiers for one's parents, family identifiers, geographic identifiers for county of birth; N=202,000 children.	1) Show that the linear FE estimator identifies a weighted average of the marginal causal effects. 2) Use a Blinder-Oaxaca decomposition to measure the contribution of different weights to the differences between linear OLS, FE, & IV estimates. IV: instrument for family income using the regional & time variation in the economic boom after the oil discovery. Also include sibling FE.	A 1 SD increase in family income: Years of Education - Models without income squared: No effects in IV or FE. Models including income squared: IV: +0.74 (child in poor family), +0.05 (child in rich family). FE: +0.22 (child in poor family), +0.02 (child in rich family).	Effects are larger in the lower part of the income distribution.
Meckel (2015). Examines the effects of anti-fraud efforts in the WIC program which resulted in the shutdown of some small operators.	1) Administrative data about WIC vendors in Texas. 2) Prices from Nielsen Homescan data: representative panel of consumers w/product level-data on all purchases; includes product type, date & location of purchase, & on the purchaser; N=430,000 purchases (11,400 stores). 3) Individual birth records that provides informatio on WIC participation of pregnant women and on ZIP code of residence of the mother, 2005-09; N= 1 million mothers on WIC.	Exploit the staggered county-level roll out of a fraud reduction program in Texas through the introduction of the Electronic Benefit Transfer (EBT) that replaced paper vouchers. DDD model: exploit variation in the exact timing of EBT rollout across counties, years and months, and WIC product and WIC store. Assumption: the exact timing of EBT rollout is uncorrelated with endogenous trends.	The anti-fraud reform: (1) Eliminated most pre-existing fraud among stores (violations declined 15%) (2) Caused 10-26% of single outlets to drop out of WIC (no change for chains) (3) Reduced WIC participation among eligible mothers by 3-5% (4) Reduced the likelihood that a mother has at least one WIC store in her ZIP code (a fall of 10-25%) (5) Increased the prices on WIC products within single outlet WIC stores by 9% (6) Reduced welfare by 3-4% of the value of benefits received	The largest declines in WIC participation among stores and women occur in high-poverty ZIP codes. Only fraudulent stores select into the program in high-poverty areas, suggesting that fraud implicitly subsidizes program access in these areas.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Milligan and Stable (2011). Effects of child benefit payments in Canada on child outcomes from 0-10.	1) National Longitudinal Survey of Children and Youth (NLSCY), provides family income & demographics; 6 biannual cycles: 1994–95 to 2004–05; followed children aged 0–11 to age 10-21; N=108,000 children. 2) Survey of Labour & Income Dynamics (SLID) used to simulate the aggregate benefits (instruments).	Exploit the variation in child benefits across province, year, and family-type (N of children in a household) due to changes in legislation. Instrument: actual child benefit level in a given year, province,, family size is instrumented with a simulated tax benefit computed using a tax & benefit calculator. Models include a set of individual/ family characteristics, and control variables for time and province effects.	An increase of \$1,000 in child benefits: Education: Repeating a school grade: no effect; Math score: +0.069 SD (+1.6%); PPVT: no effect Prob (not been diagnosed with a learning disability): +2.8pp (+1.0% = 0.16 SD) Emotional/behavioral well-being: Physical aggression: -0.106 SD (-14%)	Most significant effects are driven by boys, not girls. For girls, there is a significant effect on physical aggression (-.14 SD for boys; -.22 SD for girls).
Scholte, van den Berg, and Lindeboom (2015). Influence of economic conditions early in life on the impact of adverse life events and on physical health later in life.	1) Longitudinal Aging Study Amsterdam (LASA); 5 waves: 1992-1993, 1995-1996, 1998-1999, 2001-2002, 2005-2006, (N=2869, 2001, 1571, 1132, 799 persons). Data includes info on: functional limitations, heart disease, stroke, cancer, respiratory diseases, peripheral artery disease, diabetes and arthritis.	Ask how shocks in later life affect functional limitations in later life AND whether individuals exposed to recessions early in life respond differently to later-life shocks than other adults. Strategy: IV + individual FE. Instrument: Business cycle at birth (boom or recession). Regressions include interactions btw: (indicator for a recession at birth) * (adverse later life events).	N of functional limitations later in life: Chronic disease: +8.6% (Chronic disease)*(early-life recessions): +10.5% This result indicates that the effects of chronic diseases on functional limitations are exacerbated by adverse early-life conditions	Effects of chronic disease and (Chronic disease)*(early-life recessions) are only positive & significant among males.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity
Panel A: Policies to Increase Material Household Resources				
Rossin-Slater (2013a). Effect of closures of WIC clinics in Texas on birth outcomes.	1) Texas Birth & admin. records 2005–2009; data includes mothers' maiden name, DOB, counties of birth, ZIP codes of residence; allows linking of siblings & determining whether mothers had an operating WIC clinic in their ZIP code during pregnancy; N = 1,937,003 births (612,694 siblings). 2) WIC clinic locations come from TX Dept. of State Health Services; includes names, address/ZIP codes, & opening/closing dates in 2005 –2010 (N=578 ZIP codes; 114 experienced openings/closures).	Exploit the within-ZIP-code variation in WIC clinic openings/closings. Compare births by mothers who did & did not have a WIC clinic in their ZIP code during pregnancy & control for mother-FE with IV (to account for migration, measurement error, & the mechanical correlation between gestation & WIC participation (instrument: dummy for whether mother would have had an open WIC clinic during her current pregnancy in the ZIP code of her 1st pregnancy assuming 39 weeks gestation). Models include individual controls, YOB & MOB FE, ZIP code-FE, county linear time trends.	The presence of a WIC clinic in a mother's ZIP code of residence, during her pregnancy: Food benefit take-up: +6% Pregnancy weight gain: too little weight (<7.3 kg): -2pp; too much weight (>18 kg): +3pp (among those with <=HS educ) Diabetes: +1.3pp (among those with <=HS educ) Gestational hypertension: +1.3pp (among those with <=HS educ) Birth weight: +27gr (+0.8%) (full sample)	Strongest effects for mothers with high school or less, who are most likely eligible for WIC services (0.74% WIC take-up vs. 0.07% among other moms). The increase in BW is concentrated in the middle of the BW distribution.
Rossin-Slater (2013b). How did changes in paternity establishment laws affect young children's access to resources and health outcomes in the U.S.?	1) Paternity establishments in hospital, N=601 state-year obs. 2) CPS-CSS & March CPS, 1994-2008 child support supplements (CSS); N=8,974 who respond to CSS); 3) NHIS data 1997-2010 restricted sample of child files; provides info on child mental & physical health. 4) Fragile Families & Child Well-Being Study.	Exploit variation in the timing of in hospital paternity establishment across states. Models regress a child outcome on the in hospital paternity establishment dummy, rich individual controls, state & child birth year FE, & state-specific time trends. Author imputes birth year = survey year – child age – 1 since interview year are in March.	Paternity establishment no effects on time spent father & child. Child private health insurance: -2.65pp (-3.89%). Child physical health (asthma, ear infection): no effects. Any well-visits: -1.99pp (-2.53%). Any doctor visits: -1.48pp (-1.78%). Child mental health: no effects. Income, poverty status, or welfare benefit receipt: no effects.	No differences by mother's race.

Table 3: Two-Shock Studies

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Adhvaryu, Molina, Nyshadham, and Tamayo (2015). Examine the effect of a conditional cash transfer program on the impacts of rainfall shocks in Mexico. Outcomes measured at 12 to 21 years.	1) Baseline and follow-up surveys of HHs in Progresa; 1997, follow-ups every 6 months for the first 3 years of the program (1998 to 2000). 2) ENCEL 2003; a HH survey of the 506 localities that were part of the original evaluation. 3) Mexico's National Meteorological Service provides rainfall data, 1975-2003. Data were matched using GPS coordinates, N=14,464.	Exploit two orthogonal sources of exogenous variation: 1) Parents' resources at the time of a child's year of birth & state of residence (proxied by local rainfall) & 2) The returns to investing in education during adolescence (via the RCT program Progresa). Model includes dummy for rainfall shock, Progresa exposure, the interaction btw rainfall shock and Progresa, state FE, birth year FE, & rich controls.	Exposure to adverse rainfall in the YOB: Years of educ: -0.57. Mitigating impact of Progresa: +0.1 yrs for each year in the program. On average, Progresa mitigated 60-80% of the effect of the shock. Woodcock-Munoz tests (letter-word identification, applied problems, & dictation): -0.22 to -0.25 SD.	Effects of Progresa are larger for children with lower endowments (i.e., those who were affected by the rainfall shock).
Aguilar and Vicarelli (2015). Exposure to extreme precipitation in Mexico due to El Nino and outcomes at age 2-6.	1) 3 waves of longitudinal household data from Mexico's Progresa conditional cash transfer program: 1997, 2000, 2003; N=6,264 children. Data NOT nationally representative.	1) DD model: Compare children in villages that experienced rainfall shocks vs. children in regions that did not. Model includes individual controls + village and year of child's birth FE. 2) Mitigating impacts of Progresa: Use random selection of villages into Progresa to estimate the effect of early vs late (2 yrs difference) allocation to treatment. Use the administrative selection rule for Progresa recipients to estimate an RD.	Exposure to El Nino: Height: -0.43 to -0.71 inches (~-2% = -0.2 SD). Stunting: +13pp (0.3 SD). Weight: -0.84 pounds (-2.5%=-0.13 SD). PPVT=-15% (-0.34 SD). Working memory= -18% (-0.44 SD). Visual-spatial thinking= -13% (-0.5 SD). Gross motor skills: no effects. Effects were not mitigated by Progresa.	1) Effects were more pronounced for children affected in the 1st two years of life versus prior to birth: Height: -0.71inches vs. -0.56 inches. PPVT=-21% vs. -15%. Working memory= -19% vs. -15%. Visual-spatial thinking= -13% vs. -12%.

Table 3: Two-Shock Studies

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Gunnsteinsson, Adhvaryu, Christian et al. (2016). Effect of nutritional supplements in Bangladesh in mitigating the effects of tornados on infants.	1) RCT took place in 2001-2007, N=18,767 infants, 41 sectors (20 received supplements, 20 placebo). 2) Survey on the effects of the tornado 2005; collected data on damages, deaths (the tornado affected 17 of the 41 sectors).	Exploit data from an RCT of a nutritional supplementation program for newborns & mothers. A tornado occurred on March 20th, 2005. Authors exploit 3-sources of variation: 1) RCT of vitamin A suppl.; 2) spatial variation in tornado exposure; 3) variation in trimester of pregnancy exposed to tornado. DDD: compare babies born at different times (within & outside of a window around the tornado), across sectors affected by & unaffected by the tornado.	Tornado exposure in early pregnancy: BW: -14pp (-0.6% = -0.03 of a SD). Height: -0.54cm (-1.2% = -0.23 of a SD). Mid-upper arm circumference: -0.29cm (-0.31% = -0.35 of a SD.) Head circumference (HC): -0.54cm (-1.7% = 0.33 of a SD). Chest circumference (CC): -0.34cm (-1.1% = -0.16 of a SD).	Those treated with vitamin A at birth through the RCT were effectively protected from the shock in terms of antropometric outcomes at 6 months. There was little protective effect of maternal supplementation during pregnancy.
Rossin Slater and Wust (2015). Explore main effects and interactions between high quality preschool childcare and a nurse home visiting program. Examine effects on children and children's children.	1) Digital Atlas of the Danish Historical & Admin. Geography: includes individual & municipal-level data; source of outcomes data for 2nd generation. 2) Historical data on state-regulated CC centers: address, year established, number of children (collapsed to municipality* year*gender cells) (N=3,600 cells). 3) Nurse Home Visiting Program (NHV): Date program approval for all municipalities over 1937-1949 from the Danish National Archives. 4) Inpatient records, 1994-2010. N=869,273 observations.	DD model: Exploit the municipality*year variation in CC center approvals & in the NHV program rollout. Identifying assumptions: (1) the timing of approvals is uncorrelated w/other municipal time-varying characteristics that also predict outcomes; (2) the timing of approvals is uncorrelated with the NHV program rollout.	LT impacts of the CC program: Years of schooling: +2% Only compulsory education: -11% Labor mkt: +1.6% wages (males) Mortality: -10% (females). Intergenerational effects of CC: Years of schooling (@age 25): +0.4% Only compulsory educ @age 25: -6%. But interactions of CC and NHV program and negative, suggesting substitution: Most positive effects of child care reduced by 80% suggesting that subsidized child care much less effective when NHV is already in place.	Interaction effects on education and on income were mostly driven by males (even persistent on the second generation), while effects on mortality were larger for females.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel B: Maternity Leave Policy				
Baker and Milligan (2015). Expansion of paid maternity leave in Canada on children's outcomes at age 4-5.	1) National Longitudinal Survey of Children and Youth (NLSCY), 1994/5 to 2008/09. N~10,000 obs. Authors sample multiple cohorts before and after the reform so that any age effects average out. 2) Labour Force Survey (LFS) that includes data on labor force status.	Exploit the variation in time at home post-birth induced by the maternity leave reform extending maximum length of paid leave from 25 to 50 weeks. IV (instrument for time at home: dummy for whether child was born after the law change (i.e., December 31, 2000). Models include time trends & rich individual controls.	A 1month increase in maternal care: Cognitive: PPVT: -5.7% of a SD; "Who am I? test": -5.1% of a SD Behavioral outcomes (hyperactivity, anxiety, physical aggression, & indirect aggression): no effect	By child's gender: negative & significant effects only for boys. By mother's educ (HS or less vs. >HS): effects seem to be only negative & significant for children of more educated mothers.
Carneiro, Loken, & Salvanes (2013). Effect of an unexpected extension of paid maternity leave in Norway on the education and wages of children at age 30.	Norwegian Registry data: covering the population of Norwegians up to 2007 and a providing month and year of birth, education, labour market status, earnings, age, gender, data on families. Authors are able to link data on individuals with parents. N~42,600 obs.	Two strategies: 1) RD: comparing children of eligible mothers born just before and just after July 1, 1977 when maternity leave expanded from 12 weeks unpaid to 4 months paid plus up to 12 months unpaid. 2) DD: Treatment: Difference between mothers who had a child in June and those who had a child in July 1977. Control: Difference between mothers who had a child in June and those who had a child in July of 1975, 1977, and 1978.	Children of mothers who benefited from PAID maternity leave: HS drop-out (refers to a 3 yr HS diploma): -2pp (-7% = -0.04 SD). Ever started college (at age 30): +2pp (+5% = 0.04 SD). Wages (at age 30): +5% to +6.2%.	Children of less educated moms experienced a higher decline in HS drop out: (-3.6pp vs. -1.8pp), more college attendance (+3pp vs. no effect), BUT no effect on earnings by age 30 (children of more educated moms had 5.7% increase in earnings). Effects of the reform are larger for mothers who would have taken little unpaid leave.
Dahl, Loken, Mogstad, and Salvanes, (2013). Effect of an unexpected change in paid maternity leave in Norway on parental earning, fertility, LFP and child test scores.	1) Social security registers, 1992-onwards. Multiple years merged using individual identifiers. Authors do not observe actual eligibility, therefore, predict eligibility using labor earnings the year before birth. N=21,838.	RD: exploit the discontinuity from the reform being contingent on the birthdate of the child. A series of reforms extended paid maternity leave from 18 weeks to 35 weeks. Authors exploit this type of variation from 6 different maternity leave reforms in Norway. Since take-up is very high ITT ~ATE. Models include time trends & rich individual controls; also include quadratic trends on each side of the discontinuity.	The expansion of the paid ML: 1) Did not crowd out unpaid leave 2) Effects on individual outcomes: No effects on test scores, school drop-out, parental earnings, mother's LFP after birth (rate of returning to work two years after the birth), completed fertility, marriage or divorce: no effects. 3) Cost-benefit analysis "Paid maternity leave is regressive."	NA
Danzer and Lavy (2016). Effect of an Austrian maternity leave reform extending leave from 12 to 24 months on test scores at age 15.	1) OECD's PISA data, 2003 & 2006; includes student-reported background information (e.g., gender, birth year, month, nationality, attitudes), parents (education, nationality, occupation), & school (e.g., school programme, location, school size, resources); Not included: DOB, maternal labour market participation at the time of birth, duration of leave taking of mothers. N=764.	Exploit an amendment to parental leave legislation that came in effect on July 1, 1990 which extended paid leave from 12 to 24 months. Identification strategy uses: 1) RD 2) DD - RD Treatment group: children born after July 1st 1990 and before December 31st 1990. Control group: children born in the 1st half of 1990 (& in 1987). Models include rich mother controls & month of chld's birth FE. Estimates are ITT since actual leave taking is not observed.	No effects on PISA test scores in the full sample.	Mothers with post-secondary: +0.20 SD (math), +0.22 SD (reading), +0.21 of a SD (science), Boys: +0.33 SD (reading), +.40 (science). Mothers with less than post-secondary education: -0.14 SD (reading). Boys -.27 SD (reading), -.23 SD (science). Girls no effect. Girls no effect.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel B: Maternity Leave Policy				
Rossin-Slater (2011). Effects of extensions of unpaid maternity leave on birth outcomes and fertility in the U.S.	<p>1) Vital Statistics natality & mortality 1989-1997 collapsed into birth-year/birth-month/county/ mother-education/mother-race/mother-age/ mother marital-status cells; N=5,806,669 cells.</p> <p>2) County Business Patterns (CBP), 1989-1997, to estimate the likelihood that a resident of a county is employed in a firm with 50 or > employees/year.</p> <p>3) Quarterly Workforce Indicators (QWI) to check the firm-size procedure.</p> <p>4) 1990 Census by county of birth to construct county-level controls. Link datasets by county & year (>98% of cases matched).</p>	<p>Exploit variation in pre-FMLA maternity leave policies across states & variation in which firms are covered by FMLA provisions.</p> <p>DD & DDD:</p> <p>Compare the likely eligible & likely ineligible groups before & after FMLA, & across states.</p> <p>Likely eligible group: those employed by a firm with >= 50 employees.</p> <p>Models control for rich county-level & mother controls, month-of-birth, year-of-birth, state FE, state specific time trend.</p> <p>Estimates are ITT given that author does not observe leave-taking.</p>	<p>DDD results:</p> <p>BW: +6.5gr (+0.2%=+0.01 SD).</p> <p>Gestation length: +0.04% (0.008 SD).</p> <p>LBW: -0.2% (0.01 SD).</p> <p>Prob(preterm): -3% (0.1 SD).</p> <p>Infant mortality: -2.5% (-0.017 SD).</p> <p>Risk factors or complications at birth: no effects.</p> <p>Overall fertility: no effects.</p> <p>Parity at birth: increase in first-parity births and a decrease in later parity births. Laws encouraged some previously childless women to give birth.</p>	<p>By mother's education & marital status: Married college mothers VS. single mothers with out college:</p> <p>BW: +9.2gr (+0.3%=+0.02 SD) vs. 7.1gr (0.2%=0.016 SD).</p> <p>Gestation length: +0.06% (0.012 SD) vs. no effect.</p> <p>LBW: -0.2% (0.01 SD) vs. -0.3% (0.012 SD).</p> <p>Prob(preterm): -2.7% (0.1 SD) vs. no effect.</p> <p>Infant mortality: -10% vs. no effect.</p> <p>Changes in parity at birth driven by single, less than college mothers.</p>

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Child Care				
Aizer and Cunha (2014). Head Start effects on outcomes measured at age 7.	National Collaborative Perinatal Project (NCPPP); children & parents were followed before birth up to age 7; waves: 8 mths, 1, 4, 7 years after birth; years of birth: 1959-1965, 12 cities. N=10,157 obs. Sample includes 8-mth Bayley score; authors argue that the Bayley is more predictive of later human capital than birth weight.	Exploit the introduction of Head Start in 1966 in a model with sibling FE. Older siblings had no access to HS. Focus on the ability of initial endowments to predict parental investments at age 8 months & at age 7. Regression models include an interaction between HS_enrollment*Investments_8mths and controls for HS_enrollment, investments at 8mths, individual covariates, & family-FE.	The effect of HS* Bayley score at 8mths (Sibling-FE): Child IQ (age 4): 16.5% SD. Cogn. Achievement age 7 (ONLY signi. for those w/high initial HK): IQ: 10.4% SD. Reading: no effect. Math score: 16.0% SD. Parents invest more in highly endowed children. Preschool invest. & early HK are complements in the prod. of late HK. Degree of reinforcement increases w/family size.	The impact of HS is largest for those w/higher early cognitive development at age 8 mths. By age 7, the effect of HS on IQ & achievement have faded except for those with the highest endowments.
Attanasio, Di Maro, and Vera-Hernandez (2013). Impact of a preschool program in Colombia (Hogares Comunitarios, HC) on children's nutrition at age 2-6.	1) Survey of Familias en Accion (conditional cash transfer program in Colombia): representative of poor individuals in rural areas; focus on 65 towns where preschool program was not implemented; years 2002, 2003, & 2005-6; N=2,413 children. 2) ENDS: a more complete version of the DHS 2005; basic household demographics, children anthropometrics & participation in HC; urban areas, includes poor and less poor; N=6,179 children.	To address the endogeneity of HC participation authors instrument using: i) distance from the residence to the nearest nursery, ii) the median fee in the town, iii) the capacity of the HC programme in the town (filled + vacant HC slots / N of eligible children in the town). Model covariates include the N of children aged 2-6 in the town, the distance to other amenities (school, health centre and town hall), mother & head's ages & education levels and mother's height, as well as town-level variables.	Exposure to HC: Height-for-age: +0.88 SD (FeA sample); +1.23 SD (ENDS sample). Attendance to HC: Height-for-age: +0.4 SD (FeA sample); +0.83 SD (ENDS sample). "A 60-month-old child that has spent 24 months in an HC would be 0.35 SD (FeA) or 0.49 SD (ENDS) taller."	The impact of the programme is considerably higher for lower quantiles & almost zero for the top quantiles.

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Child Care				
Attanasio, Fernandez, Fitzsimons et al. (2014). Effects of a psychosocial and nutritional intervention in Colombia on outcomes at 12-24 months.	Baseline was collected in Feb-May 2010 & follow-up in Sept-Dec 2011; duration of the program was 18 months. Data collection includes rich measures of child cognitive tests & physical health, HH characteristics, at ages 1-2. N=1,420 children in 96 municipalities (out of the 1,100 in Colombia). Sample sizes: Control (n=318) Stimulation (n=318) Supplementation (n=308) Both interventions (n=319).	RCT in 96 towns in Colombia using a 2x2 factorial design There were 4 interventions: i) psychosocial stimulation alone (n=318), ii) micronutrient supp. alone (n=308), iii) both combined (n=319), iv) control (n=318). Models include tester effects (two for each region), baseline level of the outcomes, sex, and a second order polynomial in age.	Psychological stimulation: Cognitive scores (Bayley-III): +0.26 SD (3.7%) Receptive language: +0.22 SD (5.4%) No effects on expressive language, fine motor skills, height, weight, hemoglobin. Micronutrient supplementation had no effect on any outcomes. Interactions between psychosocial & nutritional interventions had no effects on any outcomes.	NA
Baker, Gruber, and Milligan (2015). What are the long-run impacts of interventions that foster a deterioration in non-cognitive skills?	1) Canadian National Longitudinal Study of Children and Youth; biannual btw 1994-951 & 2008-09; focus on children 0-9; N~2,000 obs. 2) Test Scores: School Achievement Indicators Program (SAIP); Pan Canadian Assessment Program (PCAP); PISA scores; 1993-2012. 3) Health and Well-Being data: Canadian Community Health Survey (CCHS) and Canadian Health Measures Survey (CHMS); 2001-2013. 4) Criminal Behavior: Stats Canada's Uniform Crime Reporting Survey (UCRS); years: 2006-2013.	In 1997, Quebec introduced a very low cost universal child care program for children aged 0-4. This program increased maternal labor supply and use of CC in Quebec (Baker, Gruber, and Milligan, 2008). DD: compare the pre and post program outcomes of children/ teenagers in Quebec, to the corresponding outcomes of child/teenagers in the rest of Canada. Models include province dummies, year dummies, as well as individual controls.	Children enrolled in child care at ages 0-4 in Quebec: Self-reported (worse) health: +0.07 SD (+3.4%) (a positive effect means worse health). Life satisfaction: +0.30 SD (+14.0%) (a positive effect means worse). Quality of life: +0.35 SD (+14.6%) (a positive effect means worse). Criminal behavior: rates of accusations: +3.7% rates of convictions: +4.6% Test scores: no effects/opposing effects across math/science "There is no strong evidence that the Quebec Family Plan had a lasting impact on children's cognitive development".	By gender: "effects on criminal behavior, aggression, and hyperactivity are concentrated in boys, who also see the largest deterioration in non-cognitive skills".

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Child Care				
Campbell, Conti, Heckman et al. (2014). Effect of Carolina Abecedarian Project on health outcomes at age 30.	Surveys of children, parents, teachers include data on cognition, personality, health, achievement, & behavior; participants followed at ages 12, 15, 21, 30, mid-30s. Collected biomedical data (e.g., blood samples). N=111 children (57 treat, 54 control).	Randomization of children into control & treatment groups. Due to VERY small samples (N=111), authors use estimation methods that involve exact (small-sample) block permutation tests + bootstrapping of standard errors.	Disadvantaged children randomly assigned to treatment at 0-5 have: 1) Fewer risk factors for cardiovascular & metabolic diseases in their mid-30s (stronger effects on males): systolic blood press.: -17mm Hg; metabolic syndrome (males): -25%; prehypertensive (females): -0.24; obesity & hypertension: difference of 38.9% btw treatments & controls. 2) More health care utilization at age 30 (males): +22.8%. 3) Lower risk of overweight in early-life (males): -40%. Those who are obese at age 30s were already obese at ages 0-5.	Larger impacts on overweight, obesity & hypertension, healthcare utilization for males.
Carneiro and Ginja (2014). Effect of U.S. Head Start program on outcomes observed in teens and young adults.	Children of the National Longitudinal Survey of Youth (CNLSY); annual survey from 1979 until 1994 and biannual since then; authors use until 2008. Nationally representative. N=5,433 children 3-5.	RD: exploit selection criteria on HH income (& on family size) Main regressions include Head Start participation, HH income (measured at age 4), & a parametric but flexible function of yr, state, family size, family struct., HH income (measured at age 4) Discontinuity in the prob(take-up of HS) around income eligibility threshold is not sharp so authors instrument using determinants of eligibility. 1st stage only signif. for males (F-stat=17).	Effects only estimated for boys (1st stage regression only signif. for boys) Participation in HS (IV results): Overweight: -29% (0.74 SD) Needs special health equipment: -29% (1.29 SD) Behavioral problems: -0.6 of a SD (not given as a %) Engagement in criminal act.: -22% (young adults) (0.56 SD)	No first stage for girls.

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Child Care				
Conti, Heckman, and Pinto (2015). The impacts of two early-life US preschool programs (Perry Project (PPP) & Carolina Abecedarian Project (ABC)) on LT health and health behaviors. N=7,400.	1) PPP longitudinal data: follow-ups collected annually from age 3 until 4th grade; includes measures of intelligence, academic aptitude, achievement tests, assessments of socio-emotional development, school records starting at kindergarten through secondary education. 2) ABC longitudinal data: follow-ups collected at ages 12, 15, 21, 30. N=7,400.	Treatment randomization with long-term follow-up: The paper accounts for small sample sizes, multiple hypothesis testing, and non-random panel attrition. Effects are estimated by gender due to both biological and behavioral considerations.	Participating in an early-childhood program: 1) PPP (outcome observed at ages 27 and 40): Prob(having a healthy diet): +15pp (males) (no SD available). Prob(engaging in regular physical activity): +33pp (females). Prob(of being a daily smoker): -20pp (males) Avg. N of cigarettes/day: falls from 8.7 @age 27 to 6.5 at @40 (males). 2) ABC (outcome observed at age 34): Obesity: no effects Overweight: no effects Prob(Diastolic blood pressure): -15% (males) Prob(Systolic blood pressure): -12% (males) Hypertension I: -76% (males) Hypertension II: -62% (males) Prob(ever been hospitalized): +35pp (males).	Both programs improved the health outcomes and healthy behaviors of males only. Externalizing behavior in early-life is a key mediator of the effect of PPP on smoking among males, while enhancements in cognitive skills are a key mediator of PPP on physical activity. Task orientation and child's BMI are important mediators for high blood pressure and hypertension in later-life (males) in ABC.
Gelber and Isen (2013). Effects of Head Start on parental investments in children.	The Head Start Impact Study was an experiment in which some children were treated with Head Start while the controls were not. Many controls were in other preschools. Outcomes were measured in the fall of 2002 (after their enrollment in HS) & in the Spring of 2003, 2004, 2005, 2006 (N=4,061 children).	Exploit the random selection of 1st-time applicants (ages 3 & 4) to HS for the fall of 2002. HS experiment: children on waiting lists for 84 nationally representative HS programs (353 HS centers) were selected into: Treatment: group enrolled in HS (N=2,479 children) Control: group that was not granted access to HS (N=1,582 children).	While enrolled in HS: Parental involvement w/child (includes all activities): +0.15 SD. Reading & writing: +0.19 SD. Math: +0.19 SD. Qualitative parenting: +0.07 SD. Rules & routines: 0.12 SD. Tracking child learning: 0.23 SD. After child was enrolled in HS: Parental investment in children: +0.06 SD. Reading & writing: no effect. Math: +0.10 SD. Qualitative parenting: +0.07 SD. Rules & routines: +0.09 SD. No effect on father involvement or parent-school involvement in either condition.	Across HS programs, programs that raised children's cognitive test scores more also raised parents' involvement w/children. No evidence of differential impacts across: i) father present; ii) gender; iii) Fall 2002 income of the parents; iv) number of siblings; v) whether child entered HS at age 3 or 4.

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Child Care				
Gertler, Heckman, Pinto, et al. (2014). Effect of psychosocial stimulation and nutrition in Jamaica on child outcomes at age 20-22.	The Jaimaic Study: Longitudinal data that follows (N=129; 64 treatment + 65 control) poor & stunted children and a comparison group (N=84) of non-stunted. Urban representative data were used to compare samples: i) the 1992 Jamaican Survey of Living Conditions; ii) the 2008 Jamaica Labor Force.	Randomized intervention: Treated/control groups were all stunted, lived in same neighborhoods, had same age/sex. The two groups differ in terms of: mother's education & weight-for-height (treated group was more disadvantaged) & mother's employment (treated group higher than control). The comparison NON-stunted group is a more advantaged group of children (although not as advantaged as the average population in urban Jamaica).	Psychological stimulation treatment: Earnings: +42% (effect sizes: na) Employment or LFP: no effect. Compared w/the NON-stunted group, treated children catch-up in earnings, while the control group (stunted children w/o intervention) lag behind in earnings. Nutrition supplementation treatment: NO effects on ANY of the outcomes.	Treated males are more likely to be enrolled in school & to be enrolled full-time. Have a higher cognitive factor & are more likely to be expelled from school. Females are more likely to increase their years of schooling, have any college education, have higher exam grades, & better externalizing & internalizing behaviors.
Havnes and Mogstad (2011). Effect of being born after a child care reform in Norway on outcomes at age 30.	1) Longitudinal database that covers every resident from 1967 to 2009, includes rich data on all HH members; N=341,170 children. 2) administrative register that covers all child care institutions eligible for public subsidies from 1972 to 2009. Datasets are merged using unique identifiers for each individual.	Exploit temporal & spatial variation in child care availability induced by the staged expansion. Compare adult outcomes for 3 to 6 year olds before/after the reform, from municipalities where CC expanded a lot & municipalities little increase. Non-linear DD methods to estimate quantile treatment effects & local linear regression estimates of the program effects by family income. Order the municipalities by the pp increase in CC coverage rates from 1976 to 1997, divide sample at the median, the upper half are treatment municipalities & lower half are the controls.	The child care reform: Earnings (age 30): +9,000 NOK peaks at the 11th percentile (+2.5%= +0.06of a SD) ; +5,000 NOK bwt the 15t-60th percentile (+1.4%= 0.03 of a SD); & then fade out. Gini coefficient: declined from .306 to .296 "universal child care has a small but non-negligible equalizing effect." Intergenerational income elasticity: -2.5pp.	Results show substantial heterogeneity in child care effects by family income. Children from high income households suffer a mean loss of 8000 NOK while children from low income households experience a gain of 9000 NOK. No differences by gender.

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel C: Child Care				
Heckman, Pinto and Savelyev (2013). Effect of Perry Preschool on outcomes up to age 40.	1) Data on the Perry preeschool randomized experiment: N= 123 children (51 females (25 treatment & 26 control) & 72 males (33 treatment & 39 control)); follow-ups: ages 3–15, 19, 27, and 40.	1) Exploit the randomized controlled trial design of the program to identify the causal effect of the treatment on measured skills and on adult outcomes. 2) Use an econometric model that estimates the relationship btw outcomes & experimentally induced changes in measured skills. Three stage procedure: 1) estimate the measurement system; 2) from the theoretical equations in 1), estimate the skills for each participant; 3) estimate the relationship btw participant skills and lifetime outcomes.	1) Program effects on cognition and personality skills (kernel density graphs): Cognition (Stanford-Binet Intelligence Test): increases only in the right tail of the distrib (and for females). Externalizing behavior: strong reductions for males (at all levels of the distrib) and females (left tail). Academic motivation: increases at all levels of the distrib except at right tail (and for females only). 2) Effect of cognition and personality skills on outcomes: Cognition: increases achievement tests and certain labor market outcomes. Externalizing behavior: affects crime, labor market, and health behaviors. Academic motivation: boosts education and reduces LT unemployment.	By gender: there are significant differences.
Kline and Walters (2016). Re-examine the Head Start Impact Study. Account for participation of controls in other preschool programs.	The Head Start Impact Study was an experiment in which some children were treated with Head Start while the controls were not. Many controls were in other preschools. Outcomes were measured in the fall of 2002 (after their enrollment in HS) and in the Spring of 2003, 2004, 2005, 2006 (N=4,061 children).	Conduct a calibration exercise that accounts for the fact that ~1/3 of Head Start children were drawn from another public preschool setting. Thus, the cost of providing preschool to these children is over-estimated if we ignore this. Also assumes that the short-run impacts of Head Start on test scores are the best predictors of future outcomes, in line with previous studies which have shown initial "fade out" followed by long-term effects.	Head Start is about as cost effective as other publicly funded preschools, and under reasonable assumptions, has positive rates of return. Ignoring the fact that Head Start draws from other preschools substantially overstates its cost.	The children who are most likely to benefit from Head Start are least likely to participate. Hence, an expansion that brought these children into the program would have even higher payoffs.

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel D: Medical Care and Insurance				
Bharadwaj, Loken, and Nielson (2013). Examine the effect of additional medical care for infants over 1500g on infant mortality and test scores in Norway and Chile.	Chile: 1) Health: Vital statistics and death records 1992-2007. N= 6,109 births in the bandwidth of VLBW. 2) Education records: 2002-2010 Universe of students 1st-8th grades. 95% cases matched. Norway: 3) Health: Medical Birth Registry, 1967-1993; universe, twins. 4) Education: Norwegian Registry Data, covers population, ages 16-74 in 1986-2008. Includes basic SES data (educ, age, labor mkt, family info, etc.). N=2,477 births in window. Test scores measures at age 6-8. 72% cases are matched.	RD: Exploit variation in birth weight around the cutoff of VLBW (1500gr) or less than 32 weeks gestation to identify effect of neonatal health care on mortality/education. Compare children just under and over 1,500 grams to examine difference in outcomes as a result of extra medical treatments.	Being VLBW compared to children just above 1,500gr: Infant mortality: -4.4pp (Chile; avg infant mortality =10.9%), -3.1pp (Norway; avg infant mortality =4%). Test scores: +0.15 of a SD (Chile; math score); 0.22 of a SD (Norway; national exam) . Introduction of surfactant therapy helped improve educational outcomes for VLBW. Predicted effects on wages: +2.7% (0.15 SD) (Chile); 1.8% (Norway).	NA
Daysal, Meltem, Trandafir, and Van Ewijk (2015). Effects of home delivery on newborn deaths in the Netherlands.	1) Perinatal Registry of the Netherlands, 2000-2008, annual dataset that links 3 datasets of individual birth records collected by midwives (LVR-1), obstetricians (LVR-2), & pediatricians (LNR), covers 99% of the primary care & 100% of the secondary care provided during pregnancy & delivery in the Netherlands, N=356,412 births. 2) Statistics Netherlands data on income & educ. at the postal code level. 3) 2005 Dutch National Atlas of Public Health for exact address and the availability of obstetric wards for each hospital.	Use the variation in distance from a mother's residence to the closest hospital with an obstetric ward (exogeneity?) as an IV for a hospital delivery. Models include year, month, & day of the week of the birth FE, rich maternal controls, and avg HH income in the postal code of residence of the mother.	Giving birth in a hospital vs. at home (IV results): A 10.81pp increase in the share of hospital births reduced 7-day (28-day) mortality by 49% (46%) btw 1980-2009). 5-minute Apgar score: no effects 1st stage: distance is a strong predictor of whether she gives birth in a hospital or at home (F-stat ~28): 7.5pp (11% at the mean).	By income: baseline results are driven entirely by births to mothers residing in postal codes with less than the median of the average monthly HH income in the postal code (1,929 euros). 2SLS estimates are similar when the sample is split by maternal ethnicity, median age (29 years), median gestational age (280 days) or median birth weight (3,410 grams).

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel D: Medical Care and Insurance				
Sievertsen and Wust (2015). Effects of longer post partum hospitalizations on mother and child readmission and children's schooling achievement at age 7 in Denmark.	1) Danish National Birth Cohort (hospital admissions), 1985-2006, N=714,562 births. 2) Survey data: Danish National Birth Cohort, 1997-2003; pregnant women were invited to participate in 2 pre-birth & up to 4 post-birth surveys (at 6 & 18 months, 7 years & 11 yrs); includes maternal health behaviors, investments in children's health & development, & mother-reported child health; N=100,000 births. 3) Data on the 9th-grade GPA are available for cohorts who completed 9th-grade in 2002-2012 (cohorts born 1987-1997).	Exploit county-by-county introduction of mandatory same-day discharge on the day of birth in a difference-in-differences framework. Models include county and year FE, as well as county-specific quadratic trends in birth year.	Same-day discharged newborns: Prob(1st-month hospital readmission): +75% (+0.15 SD). Readmission after 1st month: no change N of contacts mother & child with general practitioner in 1st month of child: +0.48 (+126% = 0.54 SD). N of contacts mother & child with general practitioner up to age 3: no effect. Children's 9th grade GPA: -0.1 SD. Test score in Danish: -0.12 SD.	Long term effects are strongest for at-risk children: "Children of at-risk mothers (defined by their age, education, income) appear to drive the negative effect of same-day discharge on schooling outcomes at age 15." GPA: declines by -0.19 SD in the at risk group.
Meyer and Wherry (2016) examine the effect of the Medicaid expansions on mortality in affected cohorts.	1) Admin data: mortality records from the National Vital Statistics System (NVSS) Multiple Cause of Death files for the years 1979 to 2011 2) March Supplements to the Current Population Survey (CPS): use a random sample of 500 children of ages 0-17 from each year of the 1981-1988 CPS and estimate the childhood eligibility for this pooled sample for each birth month N= 864 children (ages 4-23)	RD: exploit the discontinuity induced by Medicaid expansions that extended eligibility only to children born after Sept. 30, 1983. Poor children gained 5 additional years of eligibility if they were born in October 1983 rather than just one month before. Control group: cohorts of children born just before the birthdate cutoff.	Children born after September 30, 1983: Internal-cause mortality rate: Ages 4-7, 8-14, 19-23: no effect. Outcome at ages 15-18: -19% (blacks only). External-cause mortality rate: Outcome at ages 4-7: no effect. Outcome at ages 8-14: -13% (blacks only). Outcome at ages 15-18: +8% (whites only). Outcome at ages 19-23: -10% (blacks only).	By race: Medicaid expansions had a sizeable decrease in the internal mortality rate of older black teens.

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel D: Medical Care and Insurance				
Miller and Wherry (2014). Effects of Medicaid expansions to older children on health status in young adulthood.	1) National Health Interview Survey (NHIS), years 1998 to 2012 N= 95,855 individuals . 2) Administrative data on hospitalizations from the Nationwide Inpatient Sample (NIS) provided by the Healthcare Cost & Utilization Project, includes data on 46 states, N=3 million hospital visits (excluding pregnancy).	Exploit variation in the timing & generosity of Medicaid and SCHIP eligibility for pregnant women & children across states. Construct a simulated eligibility measure of the generosity of state eligibility rules to instrument for the fraction of individuals eligible for Medicaid coverage. Authors construct Medicaid coverage measures by age groups: prenatal period, ages 1-4, 5-9, 10-14, 15-18. Model: outcome regressed on Medicaid eligibility in prenatal period, ages 1-4, 5-9, 10-14, 15-18, & on individual & state-level control variables, state of residence, year of birth (age), & survey year dummies.	A ten percentage point increase in eligibility during the prenatal period (or during childhood): Obesity: -1.4pp (-7%) (no SD) (in utero). BMI: -1.5 kg/m2 (-7% = -0.25 SD) (in utero). Adult hospitalizations (excluding pregnancy): -2.7% (no SD) (ages 1-4). Preventable hospitalizations: -7% (in utero). Hospitalizations related to endocrine, nutritional, metabolic & immunity disorders: -8% (in utero). No effects on health status, on any health limitation, or on psychological distress (Kessler scale).	Larger effects of coverage in utero.
Wherry, Miller, Kaestner, Meyer (2015). Effects of Medicaid expansions to older children on health status in young adulthood.	Uses data from the Healthcare Cost and Utilization Project (individual level hospital discharge and Emergency Department records from participating states) to examine exposure to Medicaid expansions given state and year of birth on number of visits as adults. N~58,000.	RD: exploit the discontinuity induced by several early Medicaid expansions that extended eligibility only to children born after September 30, 1983. Treatment group: children in families with incomes at or just below the poverty line gained 5 additional years of eligibility if they were born in October 1983 rather than just one month before. Control group: cohorts of children born just before the birthdate cutoff.	Children born after September 30, 1983: At age 15: Hospital visits: no effect. Emergency department visits: no effect. At age 25: Hospital visits: no effect (for non-blacks) Emergency department visits: no effect (for non-blacks)	Effects were concentrated among Blacks: Hospital visits: -7% to -15% (Blacks only). Emergency department visits: -2 to -5% (Blacks only). No effects were observed on non-Blacks.

Table 4: Social and Parental Investments

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel D: Medical Care and Insurance				
Brown, Kowalski, and Lurie (2015). Expansions of Medicaid coverage to older children and effects on labor force participation and income at age 28-31.	1) IRS-Compliance Data Warehouse (CDW), 1996 -2012; allows individuals + parents to be followed; N=4,911,040 females and 5,129,194 males. Authors link children to parents in 1997, & follow the parents in all other years. 2) Medicaid Statistical Information System (MSIS). 3) Social Security Administration data on mortality.	Exploit the variation in public insurance eligibility by cohort & state due to the Medicaid & SCHIP expansions in the 1980's & 90's. Authors exploit variation in total years of eligibility during childhood. Variation is at the state, month, and age group level. Models include FE for each birth month cohort, & each state at age 15, plus individual/HH controls. IV (instrument: simulated eligibility based on the fraction of the sample eligible for Medicaid at state & cohort year, at each age from ages 0 to 18).	For each additional year of simulated Medicaid eligibility: Cumulative income and payroll tax payments (@age 31): +\$1,561 (of a base of \$35,268) (+4.4%) (no dstandard deviations provided). Income: +\$186 (on a base year of 20,623) (+0.9%). Years of education: +0.9 years (no avg. years of schooling provided).	By gender: "Females earned more in cumulative wages by age 28."
Cahodes, Kleiner, Lovenheim, and Grossman (2016). Effects of Medicaid expansions to older children on high school and college education of 22-29 year olds.	1) American Community Survey (ACS) 2005-2012, provides educational variables; allows matching each repondent to the state of birth. 2) March Current Population Survey (CPS), used to calculate Medicaid eligibility by age, state, year, & race. 3) Youth Risk Behavior Surveillance System (YRBSS) to explore mechanisms (i.e. teen health behaviors). N=5,494 obs.	Exploit the state-level expansions of Medicaid and the State Children's Health Insurance Program that took place in the 1980s & 1990s. IV (instrument for actual eligibility using Medicaid eligibility of a fixed population in each age, state, year, & race). Identification assumption: Medicaid rules are not changing due to unobserved cross-cohort trends that also affect educational attainment. Models include rich aggregate-level controls, state-of-birth FE & calendar year FE.	A 10pp increase in avg Medicaid eligibility between the ages of 0-17: IV results High school drop-out: -0.5pp (-5%) (-0.10 of a SD). College attendance: +0.7 to 1.0pp (1 to 1.5%) (0.08 of a SD). College completion: 0.9 to 1.0pp (3.3 to 3.7%) (0.08 of a SD).	By race: An interaction between Medicaid Xa d nonwhite shows that: "Medicaid expansions helped to reduce the racial gap in HS completion..." By age: Authors show results of health insurance access by age: ages 0-1 vs. ages 2-17. Find larger effects on older children.

Table 4: Policies that Affect Household Resources

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
Panel E: Policies to Increase Maternal Education				
Carneiro, Costas, and Parey (2012). Effect of changes in maternal education on health and test scores at ages 7-8 and 12-14 in the U.S.	National Longitudinal Survey of Youth 1979 (NLSY79), women and their children only; annual survey from 1979 to 1994 and biannual since. Authors use data until 2008. N=7,555 children from 3,191 mothers.	IV approach: instrument for maternal education is variation in schooling costs during the mom's adolescence (IVs: local tuition fees, distance to college, local labor market variables). Since IVs may be weak, authors also use a limited information maximum likelihood. Models include county & cohort FE, & aggregate trends as well rich controls for mother's ability.	A year of mother education (IV estimates): Whites: Cognition (PIAT): +9.4% of 1 SD (math), +5.5% (reading) (ages 7-8); +6.0% of 1 SD (math), +5.2% (reading) (ages 12-14). Behavioral problems index: -6.6% (ages 7-8), -7.7% (ages 12-14). Grade repetition: -1.5% (ages 7-8), -2.1% (ages 12-14). Health (overweight/obesity): no effect. Blacks: Cognition (PIAT): +10.3% of 1 SD (math), +7.3% (reading) (ages 7-8); +8.3% of 1 SD (math), +7.2% (reading) (ages 12-14). Behavioral problems index: -6.8% (ages 7-8), -4.9% (ages 12-14). Grade repetition: -1.7% (ages 12-14). Health (overweight/obesity): weak effects.	The effect of maternal education persists into adolescence. Heterogeneity across races.
McCrary and Royer (2011). Effect of mother's high school education on fertility and infant health in California and Texas.	1) Administrative (confidential) dataset on all births in CA & TX with data on mother's date of birth, education, infant health, pregnancy behaviors (e.g., smoking, drink), paternal characteristics; N=800,000 births per year. 2) Public-use Natality Detail Files, 1969–1988, (only years for which daily birth counts by state are available).	Exploit age-at-school-entry policies to identify the effect of female education on fertility & infant health (i.e., exploit the fact that the year in which a person starts school is a discontinuous function of exact date of birth and determines when they can legally drop out). Compare women born just before & after the school entry date. Authors claim that school entry policies do not affect fertility.	Mother was born after the school entry date: Education at motherhood: -0.14 years (-1.3%) in CA and -0.24 years (-2.1%) in TX (no standard deviations provided). No effects on Infant health (LBW, gestation, infant mortality). Risky maternal behaviors: Maternal smoking: +13% (no SD). Drinking: -20% (no SD). Mother has STDs: no effect.	By race/ethnicity: "For black women, the effect on LBW is consistent with education improving well-being, while for white women is of the opposite sign."

Table 5: The "Missing Middle" and Latent Effects

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
<p>Bharadwaj, Eberhard, and Neilson (2013). Examines effects of BW on test scores from 1st to 12th grade in Chile.</p>	<p>1) Chile's birth records, 1992-2002. Twins/siblings are identified by using a mother ID; N=15,740 twin pairs. 2) Education data comes from the RECH (National student registry) database, the SIMCE (Math, Science, & Language Arts), and the PSU dataset (college entrance exam on math & language), that consists of administrative data on the grades/test scores of every student in the country, 2002-2008; database provided by the Ministry of Educ. of Chile. Approximately 4 million students observed ~4 times.</p>	<p>Over time, depending on parental preferences (compensatory or reinforcing), test score diff's within sibling or twin pairs will converge or diverge. Parents may find it harder to invest differentially in twins. Compare OLS, sibling, and twin FE estimates.</p>	<p>A 10% increase in BW: Math & language scores: +0.04 to 0.06 of a SD. Relationship is stable from 1st grade through HS. Being VLBW: Math & language scores: -0.1 to -0.2 of a SD. OLS & twins estimators are similar in 1st grade (~0.04 of a SD) but OLS estimates decline over time (e.g., in 8th grade the OLS estimate is 0.2 of a SD & the twins estimate is 0.5 of a SD). Authors claim this is explained by parental investment.</p>	<p>By mother's educ: The relationship btw BW & test scores for children (twins) of mothers with & w/o a HS degree is statistically identical (0.04 of a SD due to a 10% increase in BW) - a possible explanation for this result is that inequality aversion does not vary by mom's education. By SES: similar relationships in low and high SES schools/families. Results show a non-linear relationship btw BW & academic outcomes.</p>
<p>Figlio, Guryan, Karbownik, and Roth (2013). Examines effects of LBW on test scores in 3-8th grade in Florida.</p>	<p>Universe of births in Florida from 1992-2002 matched to subsequent universe of Public school system records (includes children in 3rd to 8th grade) based on first & last name, DOB, SS#. Nearly all potentially matchable children are matched. Sample is conditioned on: those remaining in the state of FL & attending public school. Authors select twins (sample of twins is followed from birth through middle school). N=14,000 pairs of twins.</p>	<p>Authors estimate Twin FE models (to account for potential unobservable determinants of cognitive ability that could be correlated w/BW); neonatal health is measured using ln(BW); control for a gender dummy, and a dummy for within-twin-pair birth order. Authors hold gestation length constant. Estimates are identified by variation in fetal growth rates.</p>	<p>A 10% increase in BW: Cognitive test (Florida Comprehensive Assessment Test, FCAT): +0.045 SD (OLS: +0.031 of a SD). Math test: +0.050 of a SD. Reading: +0.039 of a SD. Predicted effects on wages are: 3/4 of those in Black, Devereux, and Salvanes (2007). Effects on cognition are 60%-88% of those found in Black, Devereux, and Salvanes (2007). These effects do not change between ages 9-14.</p>	<p>Authors estimate models by: same sex twins (vs opposite sex), gender, same sex composition (GG vs BB), mother's race, ethnicity, immigration status, education (<12, 12-15, >15), zip code median income (bottom, middle, top), marital status, age at birth (<=21, 22-29, 30-35, >=36) and find: that a 10% increase in BW is associated with a 0.04 SD increase in cognitive tests for all. Slightly larger effect for more advantaged children.</p>

Table 5: The "Missing Middle" and Latent Effects

Study	Micro - Data, N	Identification strategy and specification	Effects of the shock	Heterogeneity in mechanisms/effects
<p>Robinson (2012). Hypothesises that LBW infants with evidence of slower brain growth will have worse outcomes at age 4-7 than LBW infants with a brain sparing pattern of slower growth.</p>	<p>1) Collaborative Perinatal Project, longitudinal survey of newborns in one of 12 major U.S. cities, 1959 -1974, waves: ages 4, 8, & 12 months of age, and at 4, 7, and 8 years of age; N=47,019 individuals. 2) A 50% sample of all US births from 1968, reported by Hoffman et al. (1974); provides ability to get percentile data broken down by both gender/race;</p>	<p>Decompose LBW infants into: i) those whose head circumference is proportionate to their weight; ii) those with evidence of brain sparing. Hypothesis: "Human capital should be affected through decreased cognitive function caused by brain growth restriction in utero -- a potential mechanism for the fetal origins hypothesis." Models regress child outcome on indicators for whether a child was AGR & SGR, and on rich individual controls and sibling FE.</p>	<p>Find no cognitive effects of LBW in group with brain sparing. In group with effects on brain size: Welscher IQ scores (ages 4 & 7): -3 to -4pp (-4.2% = 0.27 of a SD). Congenital malformations: 1.6 times higher. Prob(vision, hearing, & speech abnorm.): +1.5 to 2.3 times higher Even with brain sparing: Congenital malformations: 1.3 times higher. Prob(vision, hearing, and speech abnorm.): +1.2 to 1.5 times higher.</p>	<p>NA</p>

Table 6: Summarizing the Effects of Shocks on Birth Weight, Test Scores, and Wages

Shock	Study	Elasticity
Panel A: Outcome= Birth Weight		
Alcohol	Barreca and Page (2015)	A 1-month increase in the minimum legal drinking age leads to a 0.03% decline in LBW (or a statistically non-significant 1.2% decline on BW).
Disease	Schwandt (2016)	A 10% increase in maternal influenza hospitalizations in pregnancy leads to a 0.2% decline in BW (or a 7.2% increase in LBW).
Income	Almond, Hoynes, and Schazzenbach (2011)	A 10% increase in annual income leads to a 0.5% increase in BW (or a 6.0% decline in LBW).
Income	Hoynes, Miller, and Simon (2015)	A 10% increase in annual income leads to a 1.0% increase in BW (or a 11.0% decline in LBW).
Income	Rocha and Soares (2015)	A 10% increase in rainfall shocks during pregnancy leads to a 1.8% decline in BW (no LBW estimates are provided).
Income & Stress	Lindo (2011)	Father's (own) unemployment leads to 4.8% decline in BW (or a statistically non-significant 2.5% increase on LBW).
Maternity leave	Rossin-Slater (2011)	A 1-month increase in maternity leave during pregnancy leads to a 0.16% increase in BW (or a -0.16% decline in LBW).
Nutrition	Almond and Mazumder (2011)	A 1-month increase in fetal nutritional disruption, leads to a 0.6% decline in BW (no LBW estimates are provided).
Nutrition	Rossin-Slater (2013)	A 10% increase in the availability of WIC clinics leads to a 0.4% increase in BW (or a 1.7% decline in LBW only for mothers with HS or less).
Pollution	Currie, Graff Zivin, Meckel, Neidell, Schlenker (2013)	A 10% increase in pollution (the N of districts with water contamination) leads to a 7.5% increase in LBW (no BW estimates are provided).
Pollution	Currie and Walker (2011)	A 10% increase decline in NO2 from cars (along with associated decreases in other pollutants leads to a 10% decline in LBW).
Smoking	Bharadwaj, Johnsen, and Løken (2014)	A 10% decrease in smoking (the proportion of women smoking) during pregnancy leads to a 1.3% decline in BW.
Stress	Carlson (2015)	A 10% increase in anticipated job losses in pregnancy leads to a 0.2% decline in BW (or a 16.0% increase in LBW).
Stress	Persson and Rossin-Slater (2016)	Exposure to the death of a close relative during pregnancy reduces BW by 0.5% (or a 20% increase in LBW).
Stress	Quintana-Domeque and Rodenas-Serrano (2016)	A 10% increase in violence (terrorist attacks) during pregnancy leads to a 0.2% decline in BW (no LBW estimates are provided).
Violence	Aizer (2011)	A 10% increase in violence (the probability of personal assault) during pregnancy leads to a 10.0% decline in BW (no LBW estimates are provided).
Panel B: Outcome=Test Scores		
Alcohol	von Hinke Kessler Scholder, Wehby, Lewis, and Zuccolo (2014)	A 10% increase in the probability of consuming alcohol during pregnancy leads to a 0.05 SD decline in test scores.
Disease	Bhalotra and Venkataramani (2013)	A 10% decrease in diarrhea mortality rates leads to a 0.14 SD increase in test scores.
Disease	Venkataramani (2012)	A 10% decline in the cases of malaria at the year of birth leads to a 0.2 SD increase in test scores.
Disease	Ward and Phipps (2014)	A 10 unit increase in the Influenza rate leads to a 0.3 SD decrease in test scores.
Education (mother)	Carneiro, Meghir, and Parey (2012)	1-year increase in mother's education leads to a 0.1 SD increase in test scores.

Table 6: Summarizing the Effects of Shocks on Birth Weight, Test Scores, and Wages

Shock	Study	Elasticity
Panel A: Outcome= Birth Weight		
Income	Black, Devereux, Løken, and Salvanes (2014)	A 10% increase in annual income at age 5 leads to a 0.4 SD increase in test scores.
Income	Dahl and Lochner (2012)	A 10% increase in annual income at ages 5-11 leads to a 0.15 SD increase in test scores.
Income	Milligan and Stabile (2011)	A 10% increase in annual income at ages 0-5 leads to a 0.14 SD increase in test scores.
Maternity leave	Baker and Milligan (2016)	A 1-month increase in paid maternity leave at ages 6-12 months leads to a -0.057% SD decline in test scores.
Nutrition	Almond, Mazumder, and Van Ewijk (2011)	A 1-month increase in fetal nutritional disruption (Ramadan exposure), reduces test scores by 0.07 SD.
Nutrition	Fitzsimons and Vera-Hernandez (2014)	A 1-month increase in breastfeeding leads to a 0.2 SD increase in test scores.
Nutrition	Greve, Schultz-Nielsen, Tekin (2015)	A 1-month increase in fetal nutritional disruption (Ramadan exposure), reduces female (ONLY) test scores by 0.26 SD.
Pollution (radiation)	Black, Bütikofer, Devereux, and Salvanes (2014)	A 10 unit increase in pollution (air/ground radiation) in utero leads to a 0.3 SD decline in test scores.
Pollution	Bharadwaj, Gibson, Graff-Zivin, and Nielsen (2016)	A 10 unit increase in pollution (CO) in utero leads to a 0.4 SD decrease in test scores.
Pollution	Sanders (2012)	A 10 unit decline in pollution (TSP) at the year of birth leads to a 0.1 SD increase in test scores.
Stress	Aizer, Stroud, and Buka (2016)	A 10% increase in cortisol during pregnancy leads to a 0.12 SD decrease in test scores.
Weather	Shah and Millett Steinberg (2016)	A 10% increase in the proportion of districts/year that experience a rainfall shock leads to a 0.02 SD decline in test scores.
Weather	Aguilar and Vicarelli (2015)	A 10% increase in rainfall shocks leads to a 0.02 SD decline in test scores.
Panel C: Outcome=Wages		
Alcohol	Nilsson (2015)	A 1-month increase in alcohol exposure during pregnancy leads to a 3.4% decrease in wages.
Child care	Gertler, Heckman, et al (2014)	A 1-month increase in psychosocial stimulation in early-life leads to a 1.75% increase in wages.
Child care	Havnes and Mogstad (2011)	A 10% increase in child care subsidies leads to a 1.4% increase in wages.
Disease (worms)	Baird, Hicks, Kremer, and Miguel (2016)	A 1-month increase in deworming school-aged children (age ~12) leads to a 0.15% decrease in wages.
Disease	Bhalotra and Venkataramani (2015)	A 10% decline in infant pneumonia death rates leads to a 7.0% increase in wages.
Disease	Beach, Ferrie, Saavedra, and Troesken (2016)	A 10% decrease in typhoid mortality rate leads to a 5.0% increase in wages.
Disease	Schwandt (2016)	A 10% increase in maternal influenza hospitalizations in pregnancy leads to a 1.1% decline in wages.
Health care	Brown, Kowalski, and Lurie (2015)	A 1 year increase in Medicaid coverage eligibility at ages 0-18 leads to a 4.8% increase in wages.
Maternity leave	Carneiro, Løken, and Salvanes (2015)	A 1-month increase in paid maternity leave leads to a 1.4% increase in wages.
Nutrition	Adhvaryu et al., (2016)	A 10% increase in (the availability of) iodized salt in utero leads to a 0.4% increase in wages.

Table 6: Summarizing the Effects of Shocks on Birth Weight, Test Scores, and Wages

Shock	Study	Elasticity
Panel A: Outcome= Birth Weight		
Pollution	Isen, Rossin-Slater, and Walker (2015)	A 10-unit decrease in pollution (TSP) in-utero leads to a 1.0% increase in wages.
