Abstract

Purpose of review—China has experienced an increase in the incidence and prevalence of syphilis that is especially remarkable since this infection was virtually eradicated in the country 50 years ago. The purpose of this analysis is to provide an overview of recent literature on syphilis proximate determinants and potential public health responses.

Recent findings—Per capita syphilis burden is greatest in coastal urban China. There are a number of biological, demographic, geographic, and behavioral/social proximate determinants of syphilis spread that distinguish the Chinese syphilis epidemic. These determinants portend the need for intensified syphilis control efforts, including: comprehensive testing and treatment; integration with HIV, sexually transmitted infection, and antenatal services; scale-up of novel rapid syphilis test technology, and multisectorial support.

Summary—The Chinese central government recently announced a 10-year syphilis plan to provide clear expectations for evaluating the success of local syphilis control programs and integration with HIV testing programs. Further research is needed to understand the social and behavioral determinants driving the spread of syphilis.

Keywords

China; MSM; sex worker; social; syphilis

Introduction

China implemented massive syphilis control programs during the 1950s, including empiric penicillin treatment of high-risk groups and large-scale structural interventions intended to destabilize the commercial sex industry [1]. These public health measures were largely effective in curbing the spread of syphilis and other sexually transmitted infections (STIs) for several decades. However, during the past 20 years syphilis has made a resurgence [2]. By way of comparison, there were more syphilis cases in the province of Guangdong in 2008 than reported in the entire European Union during the same year [3]. Responding to these trends, the Chinese Ministry of Health recently announced a 10-year plan for syphilis control and prevention, recognizing the reemergence of syphilis as an important public

health threat and renewing interest in syphilis control programs [4]. Many regions in China have a remarkably high incidence of syphilis [2], providing an opportunity to better understand the spread of syphilis and how it can be controlled. Although individual risk factors for syphilis infection have been well described (unprotected sex, etc.), the more proximate determinants of syphilis spread are less understood. There are several potential explanations for China's increasing syphilis burden, and better understanding the determinants of syphilis may help inform control programs and beyond. This study describes syphilis epidemiology, proximate determinants of syphilis spread, and promising public health responses in the Chinese context.

Syphilis epidemiology

Accurately estimating the incidence of syphilis is complicated by imperfect traditional serological assays that accompany frequently incomplete clinical histories. A positive treponemal test alongside a nontreponemal test with a titer of 1 : 32 could represent an incident case, prior treated infection, or a serofast result. The Chinese case definition of syphilis requires positive treponemal and nontreponemal tests and consistent clinical and physical findings [5]. Reported syphilis case data in China are augmented by cross-sectional studies, cohorts, surveillance data, and case reports in the Chinese literature.

Syphilis cases per 100 000 population in China have been consistently greater in coastal urban parts of China (Fig. 1). This tendency for cases to cluster in urban regions may be related to greater numbers of rural-to-urban migrants with higher sexual risk in those areas, but also could be a function of greater diagnostic capacity in the urban regions. Although there were administrative changes in syphilis case reporting in 2003–2004, both case report data [2] and cross-sectional data [6] suggest an expanding Chinese syphilis epidemic during the past 8 years (Fig. 2). A number of studies have found higher syphilis prevalence among men who have sex with men (MSM) [7°,8,9,10°°,11,12,13°,14], STI clinic patients [15°], and female sex workers [16,17°]. Studies of syphilis among low-risk groups such as pregnant women have found a considerable burden of disease as well [6,18,19]. For example, one study of nearly half a million pregnant women in Shenzhen found that 0.5% had syphilis [20]. These data highlight the reemergence of syphilis in China.

Potential determinants of syphilis in China

There are several potential determinants of the spread of syphilis in China: rural-to-urban migration, increased young unmarried men, limited routine screening, incomplete partner notification, stigma associated with health-seeking among high-risk groups, and perhaps lack of partial immunity.

Rural-to-urban migration on an enormous scale in China may expand localized syphilis outbreaks. The rural-to-urban migrant population exceeds 100 million individuals, and several small studies have suggested that these migrants have higher risk of sexual behavior than their rural counterparts [21,22]. There have been very few studies of syphilis outside of urban China [23], reflecting fewer STI clinics and limited treponemal diagnostics in China's rural regions. Understanding the complexity of rural-to-urban migration and how it attenuates or exacerbates sexual risk behaviors is important.

Demographic changes underway have transformed the composition and size of traditional high-risk groups, widening inroads for the expansion of syphilis [24]. Since the 1980s China has had a skewed sex ratio that demographers estimate has already caused a surplus of over 30 million unmarried men [25]. This group of largely poor, uneducated men will be underemployed, promoting rural-to-urban migration. Modeling studies [26,27[•]] and qualitative research [28] suggest that these `surplus men' may have increased sexual risk,

There have been substantive changes in the routine syphilis screening that could affect syphilis spread. In 2003–2004 the Chinese compulsory premarital health check that included syphilis testing was phased out, decreasing the pool of young, screened women. As most couples in China only have children after marriage, this routine screening likely prevented a large number of adverse outcomes related to syphilis infection among pregnant women. While antenatal syphilis screening has accelerated in several regions, none of these programs has reached the scale or uniformity of the previous premarital screening program.

Stigma related to seeking sexual health services discourages routine screening and may decrease the willingness of high-risk individuals to promptly seek sexual health services in some settings. Qualitative [29] and quantitative [30,31] studies of health-seeking behaviors among those with genitourinary symptoms reveal that many individuals do not seek care in the official standardized clinic system. Small studies of female sex workers [32,33] and rural-to-urban migrants [34] have shown that although many high-risk groups are interested in HIV and STI testing, uptake at designated clinic sites has been low.

Biological differences in syphilis transmission efficacy may exist. A study analyzing reported primary and secondary syphilis cases in the United States during a 50-year period found evidence of endogenous oscillation [35] which might be explained by partial immunity. During the 1960s and 1970s, STIs, including syphilis, were extremely rare [1]. This extraordinarily low prevalence of syphilis may have limited herd immunity, priming the Chinese population for a dramatic resurgence in disease burden. More data on syphilis transmission efficiency are needed to understand if immunological factors play a role.

Responses to China's syphilis epidemic

The large burden of syphilis in China demands more epidemiological investigation, increased screening, integration of syphilis/HIV programs, expanded partner services, more effective behavioral interventions, and multisectorial commitment. In terms of epidemiology, there have been discrepant reports regarding the burden of congenital syphilis in many regions of the country. Data from antenatal surveillance sites revealed only a modest increase in syphilis prevalence in pregnant women [36] although the number of congenital syphilis cases has continued to increase [37]. Lack of standard diagnostics and misdiagnosis of congenital syphilis [38*] on the one hand and under-reporting of cases [30] on the other emphasizes the need for further epidemiological work.

Expanding syphilis screening programs is an essential response to China's syphilis epidemic. Screening for pregnant women as part of a premarital examination must be considered and there have been promising pilot programs [20]. Expanding prenatal screening has the advantage of preventing both maternal and congenital syphilis cases, leveraging the extensive maternal child health infrastructure available in many urban regions wherein syphilis is more prevalent [20].

New rapid syphilis tests that rely on immunochromato-graphic technology will allow expanded syphilis testing. Rapid treponemal tests are fast, accurate, inexpensive, and do not require trained personnel or refrigeration [39]. Rapid syphilis testing may increase the yield of clinic-based screening programs because of shorter patient wait times, ease of use in the laboratory, and low cost. Since these tests can use pinprick blood specimens, this also represents an opportunity to augment routine clinic-based syphilis testing in sex venues and

other nontraditional testing sites. A paper comparing local rapid syphilis test results to national reference laboratory results showed excellent specificity and sensitivity [40].

China has made great strides in HIV control and prevention [41], and the strong biological and social connection between syphilis and HIV further support integration of syphilis/HIV programs. There are two complementary ways of integrating syphilis and HIV testing, and prevention, and control efforts: expanding free syphilis testing at HIV voluntary counseling and testing sites and/or expanding free HIV testing at clinics wherein individuals are tested for syphilis (STI clinics, etc). Although the first approach has met resistance due to low baseline HIV voluntary counseling and testing (VCT) uptake, the second approach has been successful in several Southern Chinese cities [15°,30]. Our recent study of over 2000 STI clinic patients in six cities found that over 80% of patients accepted integrated syphilis/HIV testing [15°].

Establishing systems of partner notification and partner services may also be important for syphilis control in China. Robust systems for partner notification are incomplete in many regions [42]. Partner notification in China is typically limited to providing case patients with a partner referral card, but comprehensive public health procedures for partner notification, testing, and follow-up do not exist. The lack of an effective partner service system in China likely increases reinfection rates among discordant couples, an especially thorny issue in the context of stigma associated with syphilis. Cost-effectiveness studies and further successful programmatic pilots in China may help to convince policymakers and local public health officials of the importance of partner notification programs.

Targeted behavioral interventions for syphilis prevention and control are also needed. Limited peer-based behavioral intervention pilots have been implemented among MSM in China [12,43,44], but more rigorous and larger studies are needed in this field. Especially in light of the high digital connectivity among Chinese MSM, online [45] or mobile phone based syphilis prevention interventions [46] should be considered. Unfortunately the literature on behavioral interventions among high-risk heterosexual individuals is similarly sparse.

The final and perhaps most essential part of syphilis control is multilevel commitment from public health, STI, maternal health, and medical agencies. The recent announcement of a 10-year syphilis control plan from the Ministry of Health in China (Table 1) gives special priority to such efforts and indicates high-level government support for expanding syphilis control efforts. This 10-year plan includes specific benchmarks for evaluating the success of the control program, focusing on integration of HIV/syphilis testing and control programs. Local syphilis control programs supported by WHO pilots, local governments, and other agencies are underway in a number of provinces now.

Conclusion

Rapid social changes across the past several decades in China have allowed for the expansion of a substantial syphilis epidemic. Although some of the proximate determinants of syphilis will be difficult to offset in the short-term (unbalanced sex ratios and surplus men, potential immunological differences), there are several discrete and changeable determinants of the syphilis epidemic. Expanding syphilis screening as part of clinic-based and community-based efforts will help ensure that infectious individuals are quickly diagnosed, treated, and counseled. Integration of syphilis testing into other critical public health and medical infrastructures, notably the HIV testing and care system, represents a feasible and scalable intervention to thwart China's syphilis epidemic. Although creating partner notification systems may take time, starting pilot programs and conducting

feasibility studies are critical early steps for these proven public health tools to make an impact in the future. Cost-effectiveness studies [47] and further policy work will help justify the expanded resources necessary to undertake these steps. The Chinese Ministry of Health's bold new syphilis control plan reveals where China hopes to be in 2015 and 2020 with respect to syphilis. Now is the time to leverage local and regional syphilis resources in China to successfully realize these benchmarks.

Key points

- After near eradication 50 years ago, syphilis has made a resurgence in China.
- According to the national case reporting system, syphilis burden is greatest along coastal urban regions in China.
- There are a number of proximate determinants of the Chinese syphilis epidemic that are related to geographic, demographic, behavioral, screening and social changes.
- A comprehensive syphilis control program should leverage these social forces and integrate syphilis programs into the already widespread systems for sexually transmitted infection clinical care, HIV care, and antenatal care.
- The Chinese Ministry of Health recently announced a major 10-year plan for syphilis prevention and control that has clear benchmarks, establishing a strong foundation to reinforce syphilis control in China.
