30 Abstract 31 In the last decade, the view of circadian oscillators has expanded from transcriptional 32 feedback to incorporate post-transcriptional, post-translational, metabolic processes 33 and ionic signalling. In plants and animals, there are circadian oscillations in the 34 concentration of cytosolic-free Ca²⁺ ([Ca²⁺]_{cvt}), though their purpose has not been fully characterised. We investigated whether circadian oscillations of [Ca²⁺]_{cvt} regulate the 35 circadian oscillator of Arabidopsis thaliana. We report that in Arabidopsis, [Ca²⁺]_{cvt} 36 37 circadian oscillations can regulate circadian clock function through the Ca2+-dependent 38 action of CALMODULIN-LIKE24 (CML24). Genetic analyses demonstrate a linkage 39 between CML24 and the circadian oscillator, through pathways involving the circadian 40 oscillator gene TIMING OF CAB2 EXPRESSION1 (TOC1). 41 42 Circadian oscillators confer competitive advantage by modulating physiology and development^{1, 2}. In Eukaryotes, circadian oscillators are comprised of feedback loops of 43 44 transcriptional regulators, however, the oscillator genes differ between the Kingdoms². 45 3. In Arabidopsis thaliana, a morning loop is formed of CIRCADIAN CLOCK ASSOCIATED1 (CCA1)⁴ and LATE ELONGATED HYPOCOTYL (LHY)⁵. PSEUDO 46 RESPONSE REGULATOR 7 (PRR7) and PRR96. The evening feedback loop involves 47 TIMING OF CAB2 EXPRESSION1 (TOC1)7 and GIGANTEA (GI)8. These loops are 48 connected through CCA1/LHY mediated repression of TOC1 expression9 and TOC1-49 mediated repression of CCA1 involving CCA1 HIKING EXPEDITION (CHE)¹⁰. 50 51 52 Circadian oscillators also incorporate post-transcriptional, post-translational and metabolic processes¹¹⁻¹⁶. In Arabidopsis, these include the F-box protein ZEITLUPE 53 (ZTL)¹⁷ regulated blue-light dependent degradation of TOC1^{15, 18, 19} and photosynthetic 54 sugars affect entrainment¹¹. Several studies have revealed the importance of ionic 55

signalling for circadian timekeeping²⁰⁻²³. In *Drosophila*, circadian oscillations of

intracellular Ca²⁺ ([Ca²⁺]) regulate cellular oscillations in vivo²³ and temperature-57 induced increases in cytosolic [Ca²⁺] are involved in entrainment²¹. 58 59 In plants, like in the mammalian suprachiasmatic nucleus, there are circadian 60 oscillations of [Ca²⁺]_{cvt} ²⁴. They are driven by cyclic adenosine diphosphate ribose-61 mediated Ca²⁺-release from internal stores^{16, 25-28} to encode information about 62 photoperiod, timing and light intensity^{29, 30}. However, the functions regulated by 63 circadian oscillations of [Ca²⁺]_{cvt} have not been identified. Therefore, it has been 64 65 conjecture whether circadian oscillations of [Ca²⁺]_{cvt} represent an input to the oscillator or part of the timing mechanism, in addition to being an output²⁴. 66 67 We show that circadian oscillations of [Ca²⁺]_{cvt} affect the abundance of CHE and affect 68 circadian period through a Ca2+-dependent regulatory protein of the plant specific 69 CALMODULIN-LIKE (CML) family. We conclude that CML24 is part of the Arabidopsis 70 71 circadian system, acting through a Ca²⁺-dependent pathway to regulate *TOC1*. 72 73 Results Circadian oscillator gene expression can be altered by [Ca²⁺]_{cvt} signals 74 We identified potential targets for [Ca²⁺]_{cvt}, by examining by microarray the response of 75 circadian oscillator transcripts to a single 24 h artificial oscillation of [Ca²⁺]_{cvt} in plants in 76 which circadian oscillations of [Ca2+]cvt were abolished, and later artificially induced 77 (Fig. 1a and Supplementary Fig. 1). [Ca2+] signals did not restore high amplitude 78 oscillations of clock transcripts like those in light and dark cycles³¹. CCA1 HIKING 79 80 EXPEDITION (CHE) was the only clock transcript whose abundance correlated with the [Ca²⁺]_{cvt} signal, having a dynamic opposite to the imposed [Ca²⁺]_{cvt} oscillation 81 82 (maximum repression 5.2 fold at 12 h, 4.5 fold at 16 h and 3.1 fold at 8 h) (Fig.1b). The 83 CCA1 dynamic was modestly altered (1.9 fold activation at 20 h and 24 h) (Fig. 1b).

This later increase in CCA1 transcript abundance might have been due to the earlier

large repression of CHE. Artificial [Ca2+] oscillation had smaller effects on other 85 86 circadian oscillator transcript abundance, the largest being a 2 fold reduction of PRR3 87 at 16 h and a 1.9 fold increase of LHY at 20 h (Fig. 1b). To test further the effects of [Ca²⁺]_{cvt} on CHE transcript abundance, we screened a 88 number of [Ca²⁺]_{cvt} agonists to identify those that had profound and persistent effects 89 90 on [Ca²⁺]_{cvt}. N-(6-Aminohexyl)-5-chloro-1-naphthalenesulfonamide hydrochloride (W7) in combination with CaCl₂ evoked sustained increases in [Ca²⁺]_{cvt}³². This Ca²⁺ agonist 91 caused a transient and large rise of [Ca²⁺]_{cvt} peaking at 848.5 ± 156.0 nM, followed by a 92 93 sustained elevation for at least 2 h (Supplementary Fig. 1). Induction of large, 94 sustained [Ca²⁺]_{cvt} increases at ZT36 and ZT48 by 2 h treatment with W7 and CaCl₂, 95 confirmed that the major transcriptional response of the circadian oscillator was a 96 repression of CHE abundance (Fig. 1c). Similar to the experiment with a single artificial 24 h [Ca²⁺]_{cvt} oscillation, the abundance of morning transcripts *CCA1* and *LHY* did not 97 alter immediately after the [Ca²⁺]_{cvt} increase (Fig. 1c). This increase in [Ca²⁺]_{cvt} 98 99 significantly altered the abundance of transcripts expressed later in the day, being an 100 activator of PRR9 and a repressor of PRR7, PRR3 and CHE (fold changes: PRR9 3.2 101 (ZT48), PRR7 2.0 (ZT48), PRR3 1.7 (ZT36) and 2.1 (ZT48), CHE 3.4 (ZT36)) (Fig. 1c). 102 Finally, the transcript levels of the evening genes were not affected (Fig. 1c). These 103 Ca²⁺-induced changes in CHE transcript did not alter the free running period of the 104 oscillator, because treating plants with the W7 solution at ZT0 and ZT12 did not alter 105 the period of CCA1:LUC (ZT0 Control 24.4 \pm 0.5 h, W7 solution 24.2 \pm 0.2 h; ZT12 Control 24.4 \pm 0.2 h, W7 solution 24.4 \pm 0.5 h; p>0.05). Thus, manipulation of [Ca²⁺]_{cvt} 106 demonstrated that both 24 h [Ca²⁺]_{cvt} oscillations and shorter-term [Ca²⁺]_{cvt} signals can 107 108 regulate CHE transcript abundance (Fig. 1).

109

110

111

A reverse genetic screen identified Calmodulin-Like 24 (CML24) as a regulator of circadian period

Because transient increases in [Ca²⁺]_{cvt} affected circadian oscillator gene abundance 112 but not period, we wished to determine whether Ca²⁺ signalling has a role in regulating 113 114 the clock in planta. We performed a screen of 75 well characterised Ca²⁺ signalling 115 mutants of transporters, transducers and sensors. Five lines had significantly increased 116 circadian period of leaf movement compared to wildtype (Fig. 2 and Supplementary 117 Table 2); vitamin C (vtc) 1-1³³ (Col-0 23.8 \pm 0.1 h, vtc1-1 24.7 \pm 0.2 h, p=0.001), 118 calmodulin-like (cml) 24-1 and the double mutant cml23-2 cml24-1 (Col-0 24.1 ± 0.1 h, 119 cml24-1 24.6 \pm 0.1 h, cml23-2 cml24-1 25.0 \pm 0.1 h, p<0.001 for both) and also cml24-1120 4 and the double mutant cm/23-2 cm/24-4 34,35 (Col-0 23.9 ± 0.1 h, cm/24-4 25.1 ± 0.1 121 h, $cm/23-2 \ cm/24-4 \ 25.6 \pm 0.1 \ h$, p<0.001 for both). $cm/23-2 \ only \ had \ a \ phenotype$ 122 when in combination with alleles of CML24 (Fig. 2), suggesting that CML24 and CML23 123 could be redundant in the regulation of the clock. None of the overexpressing (CML24-124 OX1 and CML24-OX2) or underexpressing lines (CML24-U1 and CML24-U1) affected circadian period (Supplementary Table 2). As CML24 (previously called TCH2)^{36, 37} 125 encodes a CALMODULIN-LIKE Ca²⁺-sensor^{34, 35} and two different alleles, cml24-1 and 126 127 cml24-4 had a significantly longer period than Col-0 for leaf movements (Fig. 2), we 128 decided to further characterize whether CML24 is involved in the regulation of the 129 circadian oscillator. The long circadian period of cml23-2 cml24-4 double mutants was 130 confirmed by measuring promoter activity of CCA1 fused to luciferase (CCA1:LUC) and 131 circadian oscillations of [Ca²⁺]_{cvt} (Fig. 3a-3d) (Col-0 23.7 ± 0.1 h, cml23-2 cml24-4 26.1 132 \pm 0.4 h for CCA1:LUC, p<0.001; Col-0 23.7 \pm 0.2 h, cm/23-2 cm/24-4 25.1 \pm 0.1 h for 133 35S:AEQ, p<0.001). To investigate the effect of CML24 on the central oscillator in 134 more detail, we analyzed CCA1, PRR7 and TOC1 transcript abundance in Col-0 and 135 cml23-2 cml24-4. In the third day in LL, there was a substantial delay of 4 h in the 136 phase of CCA1, TOC1 and PRR7 transcript abundance in the mutant plants (Fig. 3e), 137 consistent with the lengthening of circadian period by ~1.5 h described in Fig. 3a-d. 138 The transcript levels of the clock components were unaffected.

CML24 regulates circadian period in a [Ca²⁺]_{cvt}-dependent manner

141 Because circadian rhythms persist in conditions where the circadian oscillations of [Ca²⁺]_{cvt} are abolished, such as nicotinamide¹⁶, sucrose²⁴ or monochromatic red light²⁹, 142 circadian rhythms of [Ca2+]_{cyt} are not necessary for a rhythmic oscillator. However, we 143 could test for necessity for oscillations in [Ca²⁺]_{cvt} in the correct regulation of circadian 144 145 period by determining whether the action of CML24 in the circadian clock depends upon Ca²⁺. If the effects of the CMLs are independent of Ca²⁺, then the effects of 146 147 mutation on circadian period should be additive to treatments that abolish circadian [Ca²⁺]_{cvt} oscillations. Whereas, if the action of the CMLs is dependent on Ca²⁺, then 148 mutation should have no further effect in the presence of Ca²⁺ antagonists. 50 mM 149 nicotinamide increased the circadian period of leaf movement¹⁶ but in its presence, 150 151 cml23-2 cml24-4 was indistinguishable from the wild type (Col-0 27.7 ± 0.2 h, cml23-2 cm/24-4 28.1 ± 0.2 h, p=0.490) (Fig. 4a). Sucrose abolishes $[Ca^{2+}]_{cyt}$ oscillations²⁴, 152 153 however under high and low light conditions it has different effects on circadian period¹¹. There was no significant difference between cml23-2 cml24-4 and wild type 154 155 on 3% sucrose (high light Col-0 24.7 \pm 0.1 h, cm/23-2 cm/24-4 25.0 \pm 0.1 h, p = 0.051; 156 low light Col-0 26.4 \pm 0.2 h, cm/23-2 cm/24-4 26.9 \pm 0.2 h, p=0.061) (Figs. 4b and 4c). 157 Lastly, in monochromatic red light, the circadian period was not statistically different in 158 the cml23-2 cml24-4 mutant compared to Col-0 (Col-0 26.3 ± 0.4 h, cml23-2 cml24-4 159 26.1 ± 0.2 h p=0.410) (Fig. 4d). The lack of an effect of cml23-2 cml24-4 in conditions that abolish circadian oscillations of [Ca²⁺]_{cvt} is consistent for loss-of-function mutations 160 in putative Ca2+-sensor proteins and CML24 acting downstream of [Ca2+]cvt. 161 162 Additionally, we found that CML23 and CML24 transcript abundance (Fig. 4e) was increased in response to the artificially imposed [Ca²⁺]_{cvt} oscillation (Fig. 1a), with their 163 peaks in phase with the imposed [Ca²⁺]_{cvt} rhythm, suggesting [Ca²⁺]_{cvt} positively 164 165 regulates CML abundance. This could be explained by the presence in their promoters of the Ca²⁺-Responsive cis element CAM box (ACGCGT)³². 166

CML24 not only senses Ca²⁺, it also regulates NO³⁵ [35] as shown by high levels of NO 168 in cm/24 mutants³⁵. We therefore, tested whether the high NO in the mutants could be 169 170 the cause of the long period by two experiments. We investigated the effect of NO on 171 circadian regulation of [Ca²⁺]_{cvt} and CHLOROPHYLL A/B BINDING 172 PROTEIN2:LUC (CAB2:LUC) in wild type plants and found no evidence for a role for 173 NO, because the NO donor, SNAP, and the scavenger, cPTIO, were without effect on 174 circadian rhythms (Supplementary Fig. 2). The high NO levels found in cml23-2 cml24-175 4, were not responsible for the long period phenotype, because the mutant long period 176 phenotype persisted in the presence of cPTIO (Fig. 4f)³⁸. 177 We conclude that the effect of the cm/23-2 cm/24-4 mutations on the circadian clock requires [Ca²⁺]_{cvt} and is independent of the effects of CML24 on NO generation. 178 179 CML24 regulates circadian period by a pathway involving TOC1 and possibly 180 CHE 181 To investigate how CML24 affects circadian period, we tested whether it is involved in the [Ca²⁺]_{cvt}-mediated transcriptional regulation of circadian clock genes. The clock 182 transcripts regulated by [Ca²⁺]_{cvt} in Col-0 (Fig. 1c) were also regulated by [Ca²⁺]_{cvt} in 183 184 cml23-2 cml24-4 (Supplementary Fig. 3), suggesting that CML24 is not involved in the transcriptional regulation by [Ca2+]cvt. 185 186 187 We then investigated the genetic linkage between CML24 and components of the 188 oscillator. We studied epistatic interactions in the control of circadian rhythms of leaf 189 movement between mutations in CML23/24 and CCA1, LHY, TOC1, ZTL, ELF3, ELF4 190 and LUX. Double CML23/24 mutants were used for epistasis due to having a larger 191 measurable effect on period compared to the single CML24 mutants. We identified 192 epistasis between mutations in CML23/CML24 and TOC1 in the regulation of the 193 period of leaf movement (Fig. 5a, Supplementary Fig. 4 and Supplementary Table 3). 194 toc1-2 single mutant had a short period (C24 24.3 \pm 0.1 h, toc1-2 21.4 \pm 0.3 h, MannWhitney Rank Sum Test p<0.001; Fig. 5a)²⁹. In the triple mutant *toc1-2 cml23-2 cml24-4*, the long period arising from mutations in *CML23/CML24* was absent, having a period that was indistinguishable from the single mutant *toc1-2*, and significantly shorter than *cml23-2 cml24-4* mutant (One-way ANOVA p=1 and p<0.001, respectively) (Fig. 5a, Supplementary Fig. 4 and Supplementary Table 3). This indicates that *toc1-2* is epistatic to *cml23-2 cml24-4*. We did not find epistatic interactions between mutations in *CML23/CML24* and *CCA1*, *LHY* or *ZTL. cml23-2 cml24-4* increased period in the *cca1-*11, *lhy-*21 and *ztl-*3 backgrounds, resulting in additive phenotypes (Fig. 5b-5d and Supplementary Table 3). Analysis of genetic interactions between *CML23/CML24* and *ELF3*, *ELF4* and *LUX* is complicated by the arrhythmic phenotypes caused by loss-of-function of these evening complex genes. Triple mutants of *cml23-2 cml24-4* and members of the evening complex where therefore all arrhythmic in LL (Supplementary Fig. 4). Crossing the wild type genetic backgrounds used in this study was without effect (Supplementary Table 3).

TOC1-mediated repression of CCA1 involves CHE¹⁰. Therefore, the regulation of CHE by [Ca²⁺]_{cyt} and interaction between mutations in CML23/CML24 and TOC1, prompted investigation of whether CHE is also part of the genetic pathway by which CML24 regulates circadian period. We identified epistatic interaction between mutations in CML23/CML24 and CHE in the regulation of circadian leaf movements. As previously reported for CCA1:LUC+ rhythms, the circadian period of leaf movement in che-1 and che-2 single mutants was indistinguishable from the background (two-tailed Student's t-test p=0.461 and p=0.681, respectively; Fig. 6a and 6b)¹⁰. In the triple mutant che-2 cml23-2 cml24-4, the long period arising from mutations in CML23/CML24 was absent, being indistinguishable from the single mutant che-2 and significantly shorter than the cml23-2 cml24-4 mutant (One-way ANOVA p>0.05 and p<0.05, respectively) (Fig. 6a, Supplementary Fig. 4 and Supplementary Table 3). However, we found no evidence that che-1 was epistatic to cml23-2 cml24-4. che-1 cml23-2 cml24-4 triple mutants had

223 a significantly longer period relative to che-1 and similar to cml23-2 cml24-4 (One-way 224 ANOVA, p<0.05 and p>0.05, respectively) (Fig. 6b, Supplementary Fig.4 and 225 Supplementary Table 3). This is consistent with che-2 being a stronger allele than che-1 in the *lhy* background¹⁰, explaining why there is an epistatic interaction with *cml*23-2 226 227 cml24-4 and che-2 but not with che-1. 228 229 Because the circadian oscillator contributes to the photoperiodic regulation of flowering and cm/23-2 cm/24-4 mutants are late-flowering³⁵, we tested epistasis between 230 231 CML23/CML24 and CHE by measurement of flowering time. che-2 is an early flowering 232 mutant and, as suggested above, possibly the stronger allele (Supplementary Fig. 5). 233 As in the circadian experiments, there is an epistatic relationship between mutations in 234 CML23/CML24 and CHE in the regulation of flowering time (Fig. 6c and Supplementary 235 Fig. 5) when che-2 was used. che-2 cml23-2 cml24-4 mutant flowered at the same time 236 as che-2, and significantly earlier than cml23-2 cml24-4 (One-way ANOVA, p>0.05 and 237 p<0.05, respectively) (Fig. 6c and Supplementary Fig. 5). However, and similarly to leaf 238 movement, flowering time provided no evidence of epistasis between che-1 and cml23-239 2 cm/24-4 (Fig. 6d and Supplementary Fig. 5). 240 The data suggest that the [Ca²⁺]_{cvt}-dependent regulation of circadian period by CML24 241 242 is not directly mediated by CCA1, LHY and ZTL and that CML24 might regulate TOC1 243 and CHE, because functional copies of these two clock genes are required to express 244 the cml23-2 cml24-4 phenotype. 245 246 **Discussion** The Ca²⁺-sensor CML24 is a regulator of Arabidopsis circadian period 247 We tested the hypothesis that circadian oscillations of [Ca²⁺]_{cvt} can feed back into the 248 circadian oscillator. We demonstrate that [Ca²⁺]_{cvt} signals can regulate the expression 249

of the Ca^{2+} -binding CALMODULIN-LIKE24 (CML24) and that CML24 also regulates circadian period, with the loss-of-function phenotype being absent when $[Ca^{2+}]_{cyt}$ rhythms are abolished. We conclude that correct circadian period is dependent on CML24 and circadian rhythms of $[Ca^{2+}]_{cyt}$. Epistatic analysis suggests that TOC1 and likely CHE genetically interact with CML24 (Supplementary Fig. 6). Additionally, we show that $[Ca^{2+}]_{cyt}$ signals can regulate the expression of CHE in a CML24-independent manner and transcriptional regulation of CHE is unlikely to regulate circadian period.

It was previously reported that CML24 regulates flowering time³⁵. Our new data demonstrates that CML24 also regulates circadian period in Arabidopsis because two different alleles (cml24-1 and cml24-4) alone or in combination with the null allele of CML23 (cml23-2)³⁵, had a long circadian period (Fig. 2). We found that CML24 has robust and profound effects on period (Fig. 3). The period lengthening persisted in different clock mutant backgrounds such as cca1-11, Ihy-21 and ztl-3 (Fig. 5). The magnitude of the period lengthening of the CML24 mutants (from 0.6 to 2 h) is larger or similar to previously reported mutations in important circadian genes: prr7-11 and prr9- $1 (0-2 \text{ h})^{39}$, che-1 and che-2 (no effect on period)¹⁰, prr3-1 and prr5-3 (1 h)⁴⁰, Ink1-1 (no effect on period), Ink2-2 (1 h), Ink1-1 Ink2-2 (2 h)⁴¹, che-1/lhy and che-2/lhy double mutants have a significantly shorter circadian period (~ 0.5 or 1 h, respectively) compared to the *lhy* mutant¹⁰. *CML24-OX1* and *CML24-OX2* were without phenotype. which might be expected for a sensor protein whose activity depends on and might be limited by Ca²⁺ concentration, rather than abundance of the sensor protein. Meaning that the presence of 24 h [Ca²⁺]_{cvt} oscillations might be critical for the production of the physiological response as observed in Fig. 4a-d and that in the over-expressor lines. the Ca²⁺ signature might be still decoded. Nevertheless, the limitation of other protein targets of CML24 and activators cannot be ruled out.

CML24 binds Ca²⁺ at EF hands to cause a conformational change but has no other identified functional domains³⁵. Our data are consistent with CML23 and CML24 acting as Ca²⁺-sensors because we demonstrate that the effect of *CML23* and *CML24* mutations on circadian period depends on [Ca²⁺]_{cyt} as shown by the absence of an effect of the *cml23-2 cml24-4* mutation when circadian oscillations of [Ca²⁺]_{cyt} are suppressed^{16, 24, 29} (Fig. 4a-4d). This also demonstrates that sucrose regulates circadian period through a pathway independent of CML23 and CML24 because in low light, added sugar shortened circadian period¹¹ which was unaffected by *cm23-2 cml24-4* (Fig. 4c). In the presence of nicotinamide, the circadian period in wild type and *cml23-2 cml24-4* was the same. However, the period of the double mutant was increased by nicotinamide (Fig. 4a), suggesting that nicotinamide might target both [Ca²⁺]_{cyt}-dependent and -independent pathways, or additional Ca²⁺-sensors might be involved⁴². The Arabidopsis genome encodes over 50 CaM and CMLs^{42,43} and other Ca²⁺ sensors, which could also contribute to circadian regulation.

CML24 genetically interacts with TOC1 and possibly with CHE to regulate circadian period

The absence of the *cml23-2 cml24-*4 circadian phenotype in *toc1-2 cml23-2 cml24-*4 indicates that the CMLs proteins are unable to exert their regulator function if TOC1 is absent (Fig. 5a and Supplementary Fig. 4). *CML24* and *TOC1* are expressed in diverse tissues and organs⁴⁴ which is consistent with our genetic studies, but more studies are necessary to conclude how cytosolic CML24 regulates TOC1 function. *CHE* might have a role because there was a genetic interaction between *CML23/CML24* and *CHE* in the regulation of circadian period when the *che-2* allele was used (Fig. 6).

Because we found that Ca²⁺ alone or in combination with W7 was able to suppress *CHE* transcript abundance in Col-0 plants (Fig. 1) and in the *cml* double mutant (Supplementary Fig. 3), we suggest that the genetic interaction between

CML23/CML24 and *CHE* is not dependent on transcriptional regulation and that the effect of W7 is not through an effect on CML23/24. Additionally, circadian period was not affected by a transient increase in [Ca²⁺]_{cyt} following W7 treatment. This is not surprising, because *che* mutants, in which *CHE* transcript abundance is constitutively reduced, period is unaffected¹⁰.

Whilst we do not consider that the Ca^{2+} -induced transcriptional changes in *CHE* affect circadian period, it might be of functional significance because it is consistent with the *CHE* binding site, also known as Site IIb⁴⁵, being similar to the $[Ca^{2+}]_{cyt}$ -regulated Site II promoter element $(AGGCCCAT)^{32}$. $[Ca^{2+}]_{cyt}$ -regulation of Site II is most likely through the TCP family of transcription factors³², of which *CHE* is a member. CHE binds to the class I TCP-binding site (TBS) (GGTCCCAC) in the *CCA1* promoter and represses its expression¹⁰. In addition to *CHE*, *CCA1* transcript was the only clock gene that was modestly activated around 8 h after the last pulse of $CaCl_2$ and *CHE* repression (Fig. 1b). *CHE* oscillates 9 h out of phase with *CCA1* transcript¹⁰ and at a similar phase with $[Ca^{2+}]_{cyt}$ oscillations. Whilst we conclude that transcriptional changes in *CHE* are unlikely to mediate changes in circadian period, it raises the possibility that CHE transmits information about Ca^{2+} signals to the *CCA1* promoter.

Our data identify roles for Ca²⁺ and CML24 in the circadian clock. These findings unveil for first time in plants a function for circadian oscillations of [Ca²⁺]_{cyt} and expand the architecture of the plant circadian oscillator.

Methods

Plant material and growth

Arabidopsis mutant lines used in the reverse genetic screen were supplied generously from laboratories working in the area of Ca²⁺ signalling in plants and are listed in

Supplementary Table 2. The T-DNA insertion mutants che-1 and che-2¹⁰ and the point mutation single mutants toc1-29 and lux-446 were provided by Steve Kay (The Scripps Research Institute, USA); the T-DNA insertion mutants cca1-11, Ihy-21, elf3-4 and elf4-148 were donated by Seth Davis (University of York, UK); the T-DNA single mutant ztl-3 (SALK 035701)¹⁷ was obtained from Nottingham Arabidopsis Seed Centre (NASC), UK. To obtain the triple mutants of the circadian oscillator genes with the cml23-2 cml24-4 double mutant (Col-0), the single mutants che-1 (Col-0), che-2 (Col-0), cca1-11 (WS), Ihy-21 (WS), toc1-2 (C24), ztl-3 (Col-0), elf3-4 (WS), elf4-1 (WS) and lux-4 (C24), were crossed independently to cml23-2 cml24-4 (Col-0) double mutants to generate triple mutants. The F2 progeny was then self-fertilized to obtain an F3 generation. The F3 and F4 generations were then genotyped to ensure all the mutant alleles were homozygous. F4 or subsequent generations were used for the epistatic study. Similarly, to the circadian clock mutants, different Arabidopsis ecotypes (WS and C24) were also crossed to Col-0. Growth of Arabidopsis thaliana, photon-counting imaging of aequorin and luciferase luminescence and transformation techniques were as described in ²⁹ unless otherwise stated.

[Ca²⁺]_{cvt} manipulation

To obtain plants with undetectable circadian [Ca²⁺]_{cyt} rhythms (unentrained), meaning that [Ca²⁺]_{cyt} remained at basal levels, 35S:AEQ WS seeds²⁹ were grown in opaque 7 mm x 9 mm plastic rings sealed at the base with 0.5 µm nylon mesh (Normesh, UK) on sucrose-free 0.5 MS agar seeds, germinated without stratification and grown in continuous white light (LL) for at least 12 days. Artificial [Ca²⁺]_{cyt} rhythms were induced in these plants by step-wise addition of external CaCl₂ during the subjective day, followed by removal (Supplementary Table 1). During treatment, seedlings were floating on the mesh rafts on temperature-adjusted solutions. All experiments were repeated at least twice.

Induction of a single 24 h [Ca²⁺]_{cyt} peak was carried essentially the same except using a FLUOstar plate reader (BMG Labtech, Germany). 200 μl of treatment solution to provide final concentrations of 0 mM to 150 mM CaCl₂ (Supplementary Table 1) was injected into wells of a 96 well plate containing individual 12 day old *35S:AEQ* transformed seedlings that had previously been reconstituted with 20 μM coelenterazine (20 C, overnight). Seedlings were washed with temperature-adjusted deionized water before measurement and luminesce was measured⁴⁸. Solutions were replaced with the successive treatment every hour. Results were assessed from three independent experiments each consisting of a minimum of 12 replicates per treatment. For [Ca²⁺]_{cyt} measurements after treatment with N-(6-Aminohexyl)-5-chloro-1-naphthalenesulfonamide hydrochloride (W7) (Calbiochem) see Supplementary Methods.

Microarray analysis

Plants treated with CaCl₂ as described above to generate 24 h [Ca²⁺]_{cyt} oscillations were harvested every 4 h for 24 h. RNA was isolated as described in ¹⁶. RNA was hybridised to GeneChips *Arabidopsis* ATH1 Genome Array using NASC's International Affymetrix service. Raw intensity data were normalized across chips using RMA (http://www.bioconductor.org) automatically log transforming the expression data. Array 1-22_Calcium_12h_Rep2_ATH1 was removed from the analysis after failing hybridization quality control.

qPCR analysis

Experiment to determine the effect of W7: Col-0 and cml23-2 cml24-4 plants were treated with W7 solution (660 μ M W7 and 50 mM CaCl₂, containing a final concentration of 2.5 % (v/v) DMSO) or deionized water at ZT36 and ZT48 in constant light for 2 h and then frozen in liquid N₂.

Experiment to determine the effect of *cml23-2 cml24-4* mutation on the circadian clock transcript abundance: Col-0 and *cml23-2 cml24-4* mutant were grown at 20 °C under 12 light /12 dark and then transferred into constant light conditions. After 2 days under constant light, plants were collected every 2 h from ZT48 to ZT72.

Total RNA was extracted of three biological replicates of at least four pooled plants each, using the RNeasy Plant Mini Kit (QIAGEN) and RNase-Free DNase on-column treatment (QIAGEN). cDNA was synthesized from 500 ng RNA with the RevertAid First Strand cDNA Synthesis Kit (Thermo Scientific) using oligo(dT) primers. The genespecific products were amplified using the Rotor-Gene SYBR Green PCR Kit on a Rotor-Gene 6000 Real-Time PCR machine (QIAGEN). Primers used are detailed in Supplementary Methods. Relative transcript levels were determined by incorporating PCR efficiencies⁴⁹.

Leaf movement analysis

Analysis of circadian rhythms of the first true leaves was performed as described in ¹⁶ without experimenter knowledge of seed lines. In those experiments where nicotinamide was applied, 50 mM Nicotinamide (Sigma) or deionized water was applied once a day for 2 days before the start of imaging; 50 µl of solution was applied to the aerial parts of each seedling. The experiments were repeated twice but for the triple mutants, *cml*23-2 *cml*24-4 *che*-2 and *cml*23-2 *cml*24-4 *toc1*-2 were repeated three times. For *cml*23-2 *cml*24-4 *toc1*-2 two independent lines were used.

Photoperiodic flowering time screening

Plants were sown directly onto soil and grown in 20 C and 100 µmol m⁻² s⁻¹ in either long day (LD) conditions (16 h L:8 h D) or short day (SD) conditions (8 h L: 16 h D).

Flowering time was defined as when the emerging bolt reached a height of approximately 5 mm. Screening experiments typically had 6 to 8 plants of each line per

414	growth condition, and confirmation experiments had 15 to16 plants of each line per
415	growth condition.
416	
417	Statistical Analysis
418	All statistical tests, n number, the measure of the centre and the error bars are
419	described in figure legends when appropriate. Other statistical parameters are listed in
420	Supplementary Statistical Parameters section. For comparison between two groups,
421	two-tailed Student's <i>t</i> -test or two-sided Mann-Whitney Rank Sum Test were used. Both
422	test analyses were considered significant if p<0.05, p<0.01 and p<0.001. For
423	comparison between more than two groups, one-way ANOVA followed by Holm-Sidak
424	method or Kruskal-Wallis one-way ANOVA followed by Dunn's method or Tukey test
425	were used. ANOVA tests were performed with an alpha level of 0.05 or 0.001.
426	
427	Data availability
428	The authors declare that the data supporting the findings of this study are available
429	within the paper (Figures 1 to 6) and its supplementary files (Supplementary Figure 1 to
430	5 and Supplementary Tables 2 and 3). Additionally, microarray data are available at
431	NASC Arrays (http://arabidopsis.info/affy), experiment reference NASCARRAYS-529.

a, Circadian period estimates of leaf movement in continuous high light (80 µmol m⁻² s⁻¹

1) of Col-0 and cm/23-2 cm/24-4 plants treated with either 50 mM nicotinamide (Col-0 n=15, cml23-2 cml24-4 n=33, biological replicates) or water (Col-0 n=16, cml23-2 cml24-4 n=29, biological replicates). **b**, Circadian period estimates of CCA1:LUC rhythms in continuous high light (80 μmol m⁻² s⁻¹) or **c**, continuous low light (10 μmol m⁻² ² s⁻¹) of Col-0 and *cml23-2 cml24-*4 plants grown in the presence of either water (high light Col-0 n=7, cm/23-2 cm/24-4 n=8, low light n=16, biological replicates), 90 mM sucrose (high light n=8, low light n=16, biological replicates) or 90 mM mannitol (Col-0 n=8, cm/23-2 cm/24-4 n=7, biological replicates). d, Circadian period estimates of CCA1:LUC rhythms in Col-0 and cm/23-2 cm/24-4 plants under continuous high mixed red (660 nm) and blue (470 nm) light (80 µmol m⁻² s⁻¹) (n=4, biological replicates) and continuous monochromatic blue or red light (40 µmol m⁻² s⁻¹) (blue n=7, red Col-0 n=11 and cml23-2 cml24-4 n=10, biological replicates). e, Effect of the imposition of a ramp of external CaCl₂ (Fig. 1a) on the expression (log2) of CML24 and CML23. CaCl₂ was applied as described by the shaded areas and in Supplementary Fig. 1c. Plant material was harvested from the onset of treatment every 4 h for 24 h to extract RNA for probing with microarray. Results represent the mean (n=2 biological replicates). f, Circadian period estimates of CCA1:LUC rhythms in continuous high light (80 µmol m⁻² s⁻¹) of Col-0 (n=7 biological replicates) and cm/23-2 cm/24-4 (n=8 biological replicates) plants treated from the day before going into continuous high light either with water or 200 µM cPTIO. Period estimates were obtained by BRASS and are shown as mean ± S.E.M.

628 Data were obtained from 1 independent experiment. Experiments were repeated at 629 least twice. Single, double or triple asterisk indicate significance of ≤ 0.05, ≤ 0.01 and ≤ 630 0.001, respectively after two-tailed Student's t test analysis or two-sided Mann-Whitney 631 Rank Sum test (a (water), b (mannitol) and f). 632 Fig. 5. Epistatic Analysis of Leaf Movements Rhythms Shows that *TOC1* is 633 Functionally Linked to CML24 to Regulate Circadian Period. 634 Average normalized traces of leaf positions and FFT-NLLS analysis of the circadian 635 period for leaf movement experiments. a shows the results of cml23-2 cml24-4 with 636 toc1-2 (Col-0 n=33, C24=31, double mutant=22, clock gene mutant=24, triple 637 mutant=25), **b** with cca1-11 (Col-0 n=7, Ws-2=6, double mutant=29, clock gene 638 mutant=21, triple mutant=19), c with lhy-21 (Col-0 n=24, Ws-2=24, double mutant=22, 639 clock gene mutant=24, triple mutant=14) and **d** with ztl-3 (Col-0 n=22, double 640 mutant=25, clock gene mutant=26, triple mutant=15). Grey lines indicate cml23-2 641 cml24-4, blue clock gene single mutants and black the triple mutants, respectively. 642 Wild-type traces for leaf position were removed for clarity. All plants were grown under 643 12 h L: 12 h D cycles before the experiments. Data are presented from one experiment 644 representative of two (cca1-11, lhy-21, ztl-3) or three (toc1-2) independent 645 experiments. See also Supplementary Fig. 4 and Supplementary Table 3. Single or 646 triple asterisk indicate significance of ≤ 0.05 and ≤ 0.001 , respectively, after Kruskal-647 Wallis One Way Analysis of Variance on Ranks followed by Dunn's method was used 648 to compare the triple mutant to the single and cml23-2 cml24-4 double mutant. 649 Fig. 6. Epistatic Analyses of Leaf Movements Rhythms and Flowering Time Shows that 650 CHE is Functionally Linked to CML24. 651 Average normalized traces of leaf positions and FFT-NLLS analysis of the circadian 652 period for leaf movement experiments. a shows the results of cml23-2 cml24-4 with 653 che-2 (Col-0 n=29, cm/23-2 cm/24-4=48, che-2=47, triple mutant=40) and **b** with che-1

(Col-0 n=29, *cml23-2 cml24-4*=48, *che-1* =39, triple mutant=46). Wild-type traces for leaf position were removed for clarity. Data are presented from one experiment representative of two (*che-1*) or three (*che-2*) independent experiments (Supplementary Fig. 4 and Supplementary Table 3). Flowering time responses under long (16 h:8 h) or short days conditions (8 h:16 h) for *che-2 cml23-2 cml24-4* (**c**) and *che-1 cml23-2 cml24-4* (**d**) mutants. Number of leaves were recorded when the emerging bolt was 5 mm high. Dots represent the individual plants and the black bars the mean ± S.D. (n=16; in LD Col-0 n=15; in SD *cml23-2 cml24-4* n=15 and *che-2* triple mutant n=13). Single or triple asterisk indicate significance of ≤ 0.05 or ≤ 0.001, respectively after Kruskal-Wallis One-Way ANOVA analysis followed by Tukey test (LD) or Dunn's method (**a**, **b** and SD), when the triple mutant was compared to the *che* and *cml23-2 cml24-4* mutants. Flowering rate was calculated using the number of days since germination when the number of leaves was recorded. *che-2 cml23-2 cml24-4* mutant used was HL18 and *che-1 cml23-2 cml24-4* was HL15. An independent experiment in LD was done using three different mutants lines (Supplementary Fig. 5).
