### Abstract

The main receptors for amyloid-beta peptide ( $A\beta$ ) transport across the blood-brain barrier (BBB) from brain to blood and blood to brain are low-density lipoprotein receptor related protein-1 (LRP1) and receptor for advanced glycation end products (RAGE), respectively. In normal human plasma a soluble form of LRP1 (sLRP1) is a major endogenous brain  $A\beta$  'sinker' that sequesters some 70 to 90 % of plasma  $A\beta$  peptides. In Alzheimer's disease (AD), the levels of sLRP1 and its capacity to bind  $A\beta$  are reduced which increases free  $A\beta$  fraction in plasma. This in turn may increase brain  $A\beta$  burden through decreased  $A\beta$  efflux and/or increased  $A\beta$  influx across the BBB. In  $A\beta$  immunotherapy, anti- $A\beta$  antibody sequestration of plasma  $A\beta$  enhances the peripheral  $A\beta$  'sink action'. However, in contrast to endogenous sLRP1 which does not penetrate the BBB, some anti- $A\beta$  antibodies may slowly enter the brain which reduces the effectiveness of their sink action and may contribute to neuroinflammation and intracerebral hemorrhage. Anti- $A\beta$  antibody/ $A\beta$  immune complexes are rapidly cleared from brain to blood via FcRn (neonatal Fc receptor) across the BBB. In a mouse model of AD, restoring plasma sLRP1 with recombinant LRP-IV cluster reduces brain  $A\beta$  burden and improves functional changes in cerebral blood flow (CBF) and behavioral responses, without causing neuroinflammation and/or hemorrhage. The C-terminal sequence of  $A\beta$  is required for its direct interaction with sLRP and LRP-IV cluster which is completely blocked by the receptor-associated protein (RAP) that does not directly bind  $A\beta$ . Therapies to increase LRP1 expression or reduce RAGE activity at the BBB and/or restore the peripheral  $A\beta$  'sink' action, hold potential to reduce brain  $A\beta$  and inflammation, and improve CBF and functional recovery in AD models, and by extension in AD patients.

### Keywords

low-density lipoprotein receptor related protein-1; receptor for advanced glycation end products; Fc neonatal receptor; blood-brain barrier; cerebrovascular; Alzheimer's disease

### Introduction

Alois Alzheimer, over 100 years ago, first described the symptoms, the presence of tangles in brain and extracellular deposits of a substance in the brain and blood vessels of his patient Auguste D, for the disease that is now associated with his name, Alzheimer's disease (AD) [1]. This is a debilitating disease that affects about 5.2 million people in the US [2]. Aging is a major risk factor, and with increasing longevity by 2050 the incidence of AD will increase by about 3 fold [2]. Despite extensive research there is no treatment that alters the biological progression of the disease. However, we now understand that the brain deposits in AD are

caused by progressive oligomerization of amyloid  $\beta$ -peptides ( $A\beta$ ) to form oligomers, protofibrils and fibrils, and that these  $A\beta$  species contribute to neurotoxicity [3-5].

The relative levels and distribution of  $A\beta$  species in brain may influence the disease progression. This led to the 'amyloid hypothesis', as a possible explanation for the development of AD, in which  $A\beta$  is central to AD pathology [6-13]. A small number (<1%) of AD cases, familial AD (early-onset), is linked to genetic mutations which are associated with increased  $A\beta$  production [7,14]. The cause of the majority of AD cases, sporadic (late-onset), may be due to faulty clearance of  $A\beta$  from brain [11,13,15,16]. In this new concept, dementia in AD is associated with cerebrovascular disorder [13,17-20], which leads to accumulation of  $A\beta$  on blood vessels (cerebral amyloid angiopathy, CAA) and in the brain parenchyma, extracellular deposits [9,13,21,22], and intraneuronal lesions - neurofibrillar tangles [23].

In the interstitial fluid (ISF) of normal brain,  $A\beta$  concentration is rigorously regulated by its rate of production from the  $A\beta$ -precursor protein (APP), influx into the brain across the blood-brain barrier (BBB) mainly via receptor for advanced glycation end products (RAGE) [24] and by its rapid clearance across the BBB via low-density lipoprotein receptor related protein-1 (LRP1) [25-27] (Figure 1), and enzymatic degradation within brain [6]. Brain endothelial expression of RAGE is increased in AD mouse models and in AD patients [24,28-30] whereas LRP expression at the BBB is reduced [25,26,29], thus making it unfavorable for  $A\beta$  clearance from brain. This in turn may lead to  $A\beta$  accumulation in brain and its gradual oligomerization and greater levels of neurotoxic  $A\beta$  oligomers [3-5]. Thus, continuous removal of  $A\beta$  species from the brain by transport across the BBB and/or metabolism is essential to prevent their potentially neurotoxic accumulations in brain [31].

## Transport of $A\beta$ across the BBB

The mammalian brain is separated from blood by the BBB localized to the brain capillaries and pia-subarachnoid membranes and the blood-cerebrospinal fluid (CSF) barrier localized to the choroid plexi. The physical sites of these barriers are tight junctions between brain endothelial cells (Figure 1) and epithelial cells, respectively [13,32,33]. There are no effective barriers to diffusion of molecules between brain ISF and CSF. While the vascular barriers restrict the transport of polar solutes, rapid transport of essential hydrophobic nutrients, such as glucose and amino acids, and peptides and proteins involves specific transporter systems and/or receptor-mediated transport, respectively [13]. Using two-photon microscopy it was recently shown that mouse parenchymal neuronal dendrites are within about 13  $\mu\text{m}$  of a capillary [34], while these cells are considerably further away from CSF, especially in adult animals with large brains [32]. Therefore, the BBB plays a key role in controlling the composition of brain ISF.

$A\beta$  are small peptides (~ 4.5 kDa) and the most common isoforms are  $A\beta_{40}$  and  $A\beta_{42}$ .  $A\beta$  peptides are produced by many cells, and circulate in plasma, CSF and brain ISF mainly bound to chaperone molecules in equilibrium with a small free unbound  $A\beta$  fraction [13]. In normal human CSF and plasma,  $A\beta_{40}$  levels are greater than that of  $A\beta_{42}$  by about 10- and 1.5-fold, respectively [35]. *In vitro* studies have shown that a number of transport proteins, such as albumin, apolipoprotein E (apoE), apolipoprotein J (apoJ), transthyretin (TTR), and  $\alpha_2$ -macroglobulin ( $\alpha_2\text{M}$ ) bind  $A\beta$  [36-41]. However, in human plasma, a soluble form of LRP1, sLRP1, is a major binding protein for circulating  $A\beta$  [42]. Human sLRP1 sequesters some 70 to 90 % of plasma  $A\beta$  [42]. Using ELISA, we have shown that human sLRP1 binds the C-terminal end of  $A\beta$ , and that the interaction between sLRP1 and  $A\beta$  is completely blocked by RAP (Figure 2A).

In CSF, apoJ, apoE, TTR and  $\alpha_2\text{M}$  can bind  $A\beta$ , and influence its clearance, metabolism and aggregation [11,21,43-46]. In mice, apoJ increases the BBB clearance of  $A\beta_{42}$ , the most toxic

A $\beta$  species [44]. On the other hand, apoE disrupts the rapid LRP1-dependent clearance of free monomeric A $\beta$  across the mouse BBB, in an isoform specific manner (apoE4>apoE3 or apoE2), by redirecting A $\beta$  transport from LRP1 to very low density lipoprotein receptor (VLDLR) which internalizes A $\beta$ -apoE complexes at a slower rate than LRP1 [21]. TTR increases total brain and vascular A $\beta$  in Tg2576 mice, a model of AD [45]. In human CSF, lipocalin-type prostaclandin D synthase/ $\beta$ -trace appears to be another A $\beta$  binding agent [47].

The major clearance transport mechanism of free monomeric A $\beta$  is transcytosis across the BBB which is mediated mainly by the cell surface LRP1 localized predominantly on the abluminal side of the cerebral endothelium [25,26]. A relatively minor transport pathway under physiological conditions is by a bulk flow of the ISF into CSF through the perivascular Virchow-Robin arterial spaces, which is followed by drainage into the blood across the arachnoid villi. In normal mice, this pathway is responsible for about 10-15% of total A $\beta$  clearance [25,48]. Degradation of free A $\beta$  in brain ISF has been reported to be insignificant [21,25,26].

### **i. RAGE: Transport of A $\beta$ into brain across the BBB**

Circulating A $\beta$  enters brain in a variety of species including guinea-pigs, mice and monkeys mainly by a specific receptor-mediated transport mechanism that is dependent on RAGE expression on the luminal surface of brain vessels [24,49-56]. Similar specific receptor-mediated transport mechanisms exist for other peptides and proteins, including arginine vasopressin [57], leu-enkephalin [58,59], apoE [37], apoJ [39], activated protein C [60] and immunoglobulin G (IgG) [61]. A $\beta$  transport into brain is about 5-fold lower than that of tyrosine, an essential amino acid, that is transported rapidly across the BBB or the choroid plexus [62-64].

RAGE, a multiligand receptor in the immunoglobulin superfamily, binds a number of ligands including A $\beta$  [28,65-67]. RAGE expression is determined by the levels of its ligands. When pathogenic A $\beta$  species accumulate in AD brain, RAGE expression increases in affected cerebral vessels, neurons or microglia [28], or in transgenic models of  $\beta$ -amyloidosis and in human brain [24,28-30]. This mechanism provides the potential for exacerbating cellular dysfunction due to RAGE-A $\beta$  interactions. Soluble A $\beta$  binds RAGE in the nanomolar range, and mediates its pathophysiological cellular responses [24,28]. RAGE/A $\beta$  interaction is implicated in the development of Alzheimer's neurovascular disorder by mediating transcytosis of circulating A $\beta$  across the BBB, inflammatory responses in endothelium, brain endothelial NF- $\kappa$ B-dependent apoptosis and suppression of cerebral blood flow (CBF) [24, 28]. In addition, RAGE mediates A $\beta$ -induced migration of monocytes across the human brain endothelial cell monolayers [68].

While A $\beta$ /apoJ complex is transported into brain via LRP2 [43], this process is normally saturated by the high levels of plasma apoJ and precludes significant influx of A $\beta$  into the CNS via this route [69].

Thus RAGE, a major A $\beta$  influx receptor at the BBB, is a potential target for therapies to lower brain A $\beta$  burden, reduce neuroinflammation, and improve CBF and behavioral performance. Currently, a compound, PF04494700 (TTP488), which blocks RAGE/A $\beta$  interaction, is in a Phase 2 Clinical Trial in patients with mild to moderate AD [70]. We have shown that some tertiary amides, selected by a drug screening process, block A $\beta$  interaction with RAGE on RAGE-transfected Chinese Hamster Ovary cells which prevents oxidative stress [71]. In a mouse model of AD, these tertiary amides block A $\beta$  transport into brain across the BBB, reduce brain A $\beta$  burden and oxidative stress, and improve functional changes in CBF and performance in behavioral tests [71,72]. By extension, these new compounds could be developed as potential new therapies for AD and other RAGE-related disorders.

## ii. LRP1: Transport of A $\beta$ from brain across the BBB

LRP1, a multifunctional scavenger and signaling receptor, is a member of the LDL receptor family [73,74]. It plays a major role in the transport and metabolism of cholesterol associated with apoE-containing lipoproteins. LRP1 is synthesized as a single polypeptide precursor (600 kDa) that is processed into  $\alpha$  and  $\beta$  chains [75]. The heavy  $\alpha$ -chain of LRP1 (515 kDa), the extracellular domain, is noncovalently coupled to the 85 kDa transmembrane and cytoplasmic light  $\beta$ -chain domain. The  $\alpha$ -chain contains four ligand-binding domains (clusters I-IV), consisting of 2, 8, 10, and 11 cysteine-rich complement-type repeats, respectively [76,77]. LRP1 binds a diverse array (~40) of unrelated ligands, such as, apoE,  $\alpha$ 2M, tissue plasminogen activator (tPA), proteinase-inhibitors, blood coagulation factors (factor VIII) and A $\beta$  [26,73]. Clusters II and IV are the main ligand binding regions [44,49]. LRP1 mediates transcytosis of A $\beta$  and tPA across the BBB [25,26,78].

The cytoplasmic tail contains two NPXY, one YXXL motifs and two di-leucine motifs [79]. The YXXL motif and distal di-leucine repeat may be associated with the rapid LRP1 endocytotic rate (<0.5 seconds) [22,26,79]. In addition, the cytoplasmic domain interacts with adaptor proteins, such as disabled-1, FE65 and PSD-95, associated with cell signaling [80, 81]. The cytoplasmic tail can be phosphorylated on serine and tyrosine [82,83]. Thus, LRP1 has dual roles as a rapid cargo transporter and transmembrane cell signaling receptor.

LRP1 has been linked to AD and CAA [23,84-87], although some studies did not confirm the genetic link [88]. LRP1 and its ligands have been detected in senile plaque [89,90]. LRP1 influences the processing of APP via interaction of their cytoplasmic C-terminal domains, which requires FE67, an adaptor protein [91]. Recently, it was shown that intracellular interaction between LRP1 and APP also occurs early in the secretory process and that this requires the C-terminal of LRP1 [92]. LRP1 expressed in neurons may regulate A $\beta$  cellular uptake within brain via LRP1 ligands  $\alpha$ 2M and apoE [41,93,94]. However, LRP1 expression on neurons might not mediate A $\beta$  clearance *in vivo* since soluble brain A $\beta$  levels were increased in APP mice overexpressing functional LRP1 mini-receptors on neurons [95,96].

LRP1 expression in brain capillary endothelium is reduced during normal aging in rodents, non-human primates, and in AD [25,26,29,97]. Since LRP1 is the main receptor for A $\beta$  transport across the BBB in the direction of brain to blood, it's down regulation in brain endothelium in AD and in patients with the Dutch-type of cerebrovascular  $\beta$ -amyloidosis will reduce A $\beta$  clearance and promote A $\beta$  cerebrovascular and brain focal accumulations. Binding of A $\beta$  to LRP1 at the abluminal side of the BBB *in vivo* initiates a rapid A $\beta$  clearance via transcytosis across the BBB into blood in mice and rats [21,25,26,42,44,98]. Human A $\beta$  injected into different brain regions was found intact in murine plasma, confirming its vascular clearance [44,99]. This demonstrates rapid transcytosis of intact monomeric A $\beta$  across the BBB, from brain ISF into blood.

The affinity of A $\beta$ 40 for LRP1 is less than that of A $\beta$  peptides with a greater  $\beta$ -sheet content, such as A $\beta$ 42 and the vasculotropic mutant Dutch/Iowa (DI) A $\beta$ 40 [26]. Consequently, compared to A $\beta$ 40, the A $\beta$  peptides with higher  $\beta$ -sheet content are cleared less efficiently from brain. Similarly, the mutant Dutch A $\beta$ , containing a Glu to Gln substitution on A $\beta$ , is also cleared less efficiently from CSF to blood [100]. This may explain why the transgenic Tg DI/Swe mice (Dutch, Iowa and Swedish mutations, Thy-1 APP DI/Swe mice) develop robust A $\beta$  brain accumulation much earlier than Tg2576 A $\beta$ -overproducing mice despite extremely low levels of human APP in brain and low A $\beta$  production from neurons [26,101]. Thus, faulty vascular A $\beta$  clearance may significantly contribute to A $\beta$  accumulation in brain and to AD pathogenesis.

We have shown that both recombinant LRP-II and LRP-IV avidly bind free A $\beta$ 40 and A $\beta$ 42 *in vitro* by surface plasmon resonance analysis [26] and by ELISA using the N-terminal specific anti-A $\beta$  antibody [42,44]. However, the C-terminal specific antibodies, (BA27, Takeda Pharmaceutical Co., Ltd.) did not detect A $\beta$  bound to immobilized LRP-IV (Figure 2B), as reported [102]. RAP completely displaces A $\beta$ 40 binding to immobilized LRP-IV cluster (Figure 2B), as reported [102], but does not interact with A $\beta$  (Figure 2C). RAP, an intracellular ER (endoplasmic reticulum) molecular chaperone for the LDL receptor family, binds to LRP1 with high affinity, and not only prevents premature ligand binding to intracellular LRP1 but also is required for proper LRP1 folding [103]. Since the N-terminal specific, but not C-terminal specific, anti-A $\beta$  antibody detected A $\beta$  bound to LRP-IV it is conceivable that the C-terminal sequence of A $\beta$  binds to LRP-IV.

*In vitro* studies, using an epithelial monolayer transport model, Madin-Darby Canine Kidney (MDCK) cells, transfected with LRP1 mini-receptor containing cluster IV (mLRP4) on the basolateral membrane, confirms LRP1 A $\beta$  endocytosis at the abluminal side of the BBB which is then followed by A $\beta$  degradation [104]. In contrast to *in vivo* data showing a role of P-glycoprotein (Pg-P) in the clearance of A $\beta$  from brain [97], Pg-P was not involved in A $\beta$  transport across the MDCK monolayer [104]. It is possible that the MDCK monolayers may lack the unique properties of brain endothelial monolayers which might account for lack of A $\beta$  transcytosis. It is also possible that the A $\beta$  degradation observed in MDCK monolayers over longer periods of time is compatible with systemic clearance of A $\beta$  via kidneys [42]. Recently, it has been confirmed that a conditional immortalized endothelial cell line from rat brain (TR-BBB cell) binds and rapidly internalizes free A $\beta$  via LRP1 [102].

Other lipoprotein receptors, such as low-density lipoprotein receptor and VLDLR appear to have no major role in transport of free monomeric A $\beta$  across the BBB, into blood [26], but their role in transporting A $\beta$  bound to its chaperone proteins, apoE and apoJ, are becoming clearer [21,44]. A $\beta$  clearance may be influenced by apoE, apoJ and  $\alpha$ 2M, known ligands for LRP, but formation of A $\beta$  complexes with either of those ligands has not been shown in the CNS *in vivo* during relatively rapid clearance studies [25,26]. ApoE and A $\beta$ /apoE complexes are slowly cleared from brain compared to A $\beta$  [21,46].

## Vascular-restricted genes in the control of LRP1 expression in cerebral vessels

Transcription profiling of human brain endothelial cells indicated that a subset of age-independent genes is altered in AD compared to age-matched controls [105]. Expression of mesenchyme homeobox gene 2 (*MEOX2*) also known as growth arrest-specific homeobox (*GAX*), which is restricted to the cardiovascular system in adults, is greatly reduced at the BBB in AD compared to age-matched controls, and this is associated with downregulation of LRP1 and A $\beta$  brain accumulation, cerebral hypoperfusion and aberrant angiogenesis and vascular remodeling [105]. In vascular smooth muscle cells (VSMC) from small cerebral arteries serum response factor (SRF) and myocardin (*MYOCD*), two interrelated transcription factors that control VSMC differentiation, are upregulated in AD. This produces a hypercontractile phenotype in small cerebral arteries through *SRF/MYOCD*-directed expression of genes regulating several contractile proteins and genes that regulate calcium homeostasis and are involved in the regulation of smooth muscles contraction that reduces CBF [106]. Recently, it was shown that *SRF/MYOCD* overexpression in VSMC transcriptionally downregulates LRP1 through *SRF/MYOCD*-directed expression of sterol regulatory element binding protein-2 (*SREBP2*), which in turn reduces the cell surface LRP1 expression and A $\beta$  clearance by VSMC in AD, as well as the degree of CAA and focal parenchymal brain A $\beta$  accumulations in mouse models of AD and AD patients [22]. These two genes, *MEOX2* and *SRF/MYOCD* and/or their protein products are potential targets for therapeutic development for AD and CAA.

## Systemic A $\beta$ clearance

A $\beta$  systemic clearance is reduced with age in squirrel monkeys, and this is associated with enhanced A $\beta$  deposition in brain [52,54]. Age-dependent reduction in systemic A $\beta$  clearance may reduce the 'sink action' for A $\beta$  clearance from brain and/or increase RAGE-dependent free A $\beta$  transport across the BBB into the brain. The rapid peripheral clearance of A $\beta$  is mediated mainly by hepatic LRP1, and this is blocked by RAP [107]. Reduced hepatic LRP1 levels are associated with decreased peripheral A $\beta$  clearance in aged rats [107]. Insulin increases LRP1 levels in hepatic plasma membrane, and this in turn enhances peripheral A $\beta$  clearance, which is completely blocked by RAP [108]. While the role of insulin in type II diabetes mellitus related vascular dementia is still unclear, it is possible that faulty LRP1-mediated hepatic A $\beta$  clearance may contribute to A $\beta$  accumulation in brain.

## Transport of A $\beta$ across the BBB during A $\beta$ immunotherapy

The role of immunotherapy in AD has been extensively reviewed recently [109,110]. Since the accumulation of A $\beta$  is generally believed to play a causative role in AD, a number of therapies are being developed to reduce formation or increase clearance of A $\beta$  from brain [111]. Immunotherapy, active and/or passive, has been shown to be effective in reducing brain A $\beta$  burden in mouse models of AD [112-120], normal aged dogs [121] and monkeys [122, 123]. In contrast to mouse models of AD, in the aged dogs there was no significant improvement in cognitive function after A $\beta$  immunization [121]. While A $\beta$  immunization has been shown to have a number of beneficial effects in models of AD, there may be some unwanted side effects, such as increased CAA, increased T lymphocytes infiltration in brain and leucoencephalopathy [110]. In addition, some anti-A $\beta$  antibodies may exacerbate CAA-associated microhemorrhage [124,125]. In AD patients, even though clinical trials with A $\beta$  immunotherapy were terminated due to neuroinflammation in about 6% of subjects, there were encouraging data regarding possible reductions in brain A $\beta$  levels [126].

In addition to the role of microglia in A $\beta$  clearance, the BBB mechanisms by which anti-A $\beta$  clears brain A $\beta$  fall into two categories: peripheral A $\beta$  'sink action' and central action. Sequestration of plasma A $\beta$  by some anti-A $\beta$  antibodies may enhance the endogenous 'sink action' of sLRP1 which in turn could alter A $\beta$  transport dynamics across the BBB [127-129]. Also, the formation of anti-A $\beta$  antibody/A $\beta$  immune complexes in plasma reduces free A $\beta$  transport into brain via RAGE [24,129]. The peripheral 'sink action' can also be enhanced by other A $\beta$ -binding agents, such as gelsolin, MG1 (a ganglioside) [130] or recombinant LRP1 clusters [42], all of which have been shown to reduce brain A $\beta$  burden in a mouse model of AD. Recombinant LRP-IV cluster can effectively sequester plasma A $\beta$ 40 and A $\beta$ 42 present in human AD patient plasma and in plasma of a mouse model of AD [42].

Clearance of A $\beta$  may also depend on the entry of some anti-A $\beta$  antibodies (IgG) into the brain. IgGs with a pK close to 7.4 are transported into the brain from the cerebral circulation by a saturable mechanism across the BBB [61]. In addition, they can enter the brain by passive diffusion at sites deficient in BBB [131-133]. Within brain, anti-A $\beta$  antibodies may disrupt the formation of A $\beta$  aggregates and solubilize A $\beta$  deposits. The anti-A $\beta$  antibody/A $\beta$  immune complexes may be cleared by Fc-dependent activation of microglia followed by phagocytosis of A $\beta$  deposits [120,134,135] and Fc-independent mechanisms [115,136]. In addition, anti-A $\beta$  antibody/A $\beta$  immune complexes are rapidly transported across the BBB via neonatal Fc receptor for IgG (FcRn) that is present in the adult brain endothelium [129,137,138] (Figure 1). Although, the mechanism of FcRn-dependent transcytosis of IgG is unclear, it has been suggested that FcRn mediates A $\beta$  transcytosis across the BBB after anti-A $\beta$  antibody/A $\beta$  immune complexes are internalized at the abluminal surface of the brain endothelium [129, 138] (Figure 1).

In Tg-SwDI mice, a AD mouse model that exhibits early and robust cerebrovascular deposits due to reduced cerebrovascular LRP1 levels related to the low affinity of the DI-A $\beta$  for LRP1 [26,101], A $\beta$  immunization had no effect on parenchymal or vascular A $\beta$  deposits [139]. However, injection of purified anti-A $\beta$  antibodies from plasma of immunized mice into the hippocampus rapidly cleared diffused A $\beta$ , as reported [140], but not vascular amyloid deposits [139]. These results may suggest that while some anti-A $\beta$  antibodies clear brain A $\beta$ , their efficacy is determined by the levels of anti-A $\beta$  antibody in brain ISF at the site of A $\beta$  deposits, and by the levels of cell surface LRP1 at the BBB.

## Conclusion

RAGE and LRP1 on the BBB and sLRP1 in plasma play a key role in controlling brain ISF A $\beta$  concentration. In plasma, sLRP1 sequesters A $\beta$  and maintains the peripheral ‘sink’ action which maintains continuous A $\beta$  clearance from brain. The C-terminal sequence of A $\beta$  interacts with sLRP1 and LRP-IV cluster. In AD, RAGE levels at the BBB are increased and LRP1 levels at the BBB and the capacity of sLRP1 binding of peripheral A $\beta$  are reduced, favoring A $\beta$  accumulation in the brain. Thus, therapies focused on upregulation of the cell surface LRP1 levels, reducing RAGE activity on brain endothelial cells and/or restoring the peripheral A $\beta$  ‘sink’ action by replacement of sLRP1 in plasma, as for example with recombinant high affinity A $\beta$  binding LRP1 clusters or some anti-A $\beta$  antibodies, represent promising approaches to control brain A $\beta$  levels and the associated pathology by targeting transport processes at the BBB.

**Figure 1. Schematic diagram showing the blood and brain compartments, and the roles of the cell surface receptors LRP1 and RAGE, and FcRn and soluble LRP (sLRP) in the regulation of Aβ transport across the blood-brain barrier (BBB)**

See text for details. RAGE (receptor for advanced glycation end products), LRP1 (low-density lipoprotein receptor related protein 1), FcRn (neonatal fragment crystalline (Fc) receptor) and TJ (tight junctions between cerebrovascular endothelial cells).

**Figure 2. A $\beta$  binds to human plasma derived sLRP and human recombinant LRP-IV cluster but not to RAP using ELISA**

Briefly, 10  $\mu g/ml$  human sLRP, recombinant LRP-IV or RAP were coated on microtiter plates and blocked with protein-free blocking buffer (Pierce 37570). For sLRP and LRP-IV, 100 nM A $\beta$ 40 was added and incubated in HBSC, pH 7.4, for 2 hours at room temperature. For RAP, various A $\beta$ 40 concentrations (0, 1, 40, 1 and 100 nM) were used. After washing with HBSC containing 0.05% Tween-20, the N-terminal specific (Cell Signaling Cat # 2454, 1 $\mu g/ml$ ) or C-terminal specific (BA27, WAKO ELISA kit) primary antibodies were added and incubated overnight. The secondary antibody for the N-terminal anti-A $\beta$  antibody was goat anti-rabbit (Dako; 1:2000), while the C-terminal specific primary antibody was already HRP-conjugated. The reaction was developed with 3,3',5,5' tetramethylbenzidine (TMB; KPL, Gaithersburg, MD) and stopped with 1M HCl. Absorbance was read at 450 nm. A $\beta$  bound to immobilized human plasma derived sLRP (**A**) or immobilized recombinant human LRP-IV cluster (**B**) in the absence or presence of RAP (1  $\mu M$ ) was detected using an N-terminal specific (white bars) or a C-terminal specific (black bar) anti-A $\beta$  antibody ( $\alpha A\beta$ ). **C**, No significant binding of monomeric A $\beta$ 40 to RAP was detected using the N-terminal specific anti-A $\beta$  antibody. In **A-C**, values are mean + standard error of the mean, n=3 for each group. Pairs of groups were statistically analyzed using students t-test. These are previously unpublished data from the Zlokovic laboratory.
