ABSTRACT

Hahn, C.J., S.G. Warren, and J. London, 1994: Climatological Data for Clouds Over the Globe from Surface Observations, 1982-1991: The Total Cloud Edition. NDP026A, Carbon Dioxide Information Analysis Center, Oak Ridge National Laboratory, Oak Ridge, TN. (Also available from Data Support Section, National Center for Atmospheric Research, Boulder, CO.)

Routine, surface synoptic weather reports from ships and land stations over the entire globe, for the ten-year period December 1981 through November 1991, were processed for total cloud cover and the frequencies of occurrence of clear sky, precipitation, and sky-obscured due to fog. Archived data, consisting of various annual, seasonal and monthly averages, are provided in grid boxes that are typically $2.5^{\circ} \times 2.5^{\circ}$ for land and $5^{\circ} \times 5^{\circ}$ for ocean. Day and nighttime averages are also given separately for each season. Several derived quantities, such as interannual variations and annual and diurnal harmonics, are provided as well. This data set incorporates an improved representation of nighttime cloudiness by utilizing only those nighttime observations for which the illuminance due to moonlight exceeds a specified threshold. This reduction in the night-detection bias increases the computed global average total cloud cover by about 2%. The impact on computed diurnal cycles is even greater, particularly over the oceans where is found, in contrast to previous surface-based climatologies, that cloudiness is often greater at night than during the day.

. .

1. INTRODUCTION

This report describes a data archive that contains global coverage of analyzed cloud data. The cloud data contained in this archive (the "Total Cloud Edition") are for total cloud cover. In addition, the frequencies of occurrence of clear sky, precipitation, and sky-obscured due to fog (collectively referred to here as "weather types") are also included. Analyses of cloud types are not provided here. All data utilized here were obtained from routine, surface synoptic weather reports for the ten-year period December 1981 through November 1991. The specific contents of the archive are described in Section 3. Briefly, the archive contains various annual, seasonal and monthly averages for total cloud and the three weather types in grid boxes that are typically $2.5^{\circ} \times 2.5^{\circ}$ for land and $5^{\circ} \times 5^{\circ}$ for ocean. Several derived quantities, such as interannual variations and annual and diurnal harmonics, are also provided.

Previously the authors prepared a similar cloud data archive that spanned the years 1930 to 1981 (Hahn et al., 1988). Some of the data contained in that archive were presented in published atlases (Warren et al., 1986, 1988). The present archive represents not only an extension of the time period analyzed, but an improvement in the analysis scheme that results in more reliable estimates of cloudiness at night. This not only leads to more accurate daily averages, but, more significantly, leads to a more reliable determination of diurnal cycles than has been obtained previously from surface observations on a global scale.

2. DATA SOURCE AND ANALYSIS

A. Data Sources

For land stations, synoptic weather reports were obtained from the National Meteorological Center (NMC). Only those stations which have been assigned official station numbers by the World Meteorological Organization (WMO) were utilized. About 124 million reports were available for cloud analysis for the 10-year period December 1981 through November 1982 (referred to as 1982-91). Synoptic reports are recorded 8 times per day: 00, 03, 06, 09, 12, 15, 18, 21 GMT. However, many stations report only every 6 hours (notably those in the United States and Australia), some less often, and some only during the daytime.

Ship reports were obtained from the Comprehensive Ocean-Atmosphere Data Set (COADS), Interim Product CMR5 Reports (Woodruff et al., 1987). There were 14.4 million reports available for cloud analysis over the oceans.

B. Data Analysis

1) Processing of Weather Reports.

Synoptic weather reports are coded according to the system given by the World Meteorological Organization (WMO, 1988). The information in these reports that relates to cloud analysis is summarized in Table 1. For the total cloud and weather type analyses reported here, only N, ww, and

 I_x are of direct relevance. However, N_h , C_L , C_M and C_H were used in error checking. Definitions of the cloud and weather types analyzed here are given in Table 2.

The flow chart in Figure 1 shows the processing and quality control checks performed on each weather report read from the original archives (NMC or COADS). The percentage of reports discarded at each stage of the processing is indicated. Land and ship reports required slightly different checks in the early stages of processing but were treated identically below the horizontal dashed line in the upper portion of the figure. If a land station did not have a WMO station number it was discarded (many of these were from the United States), thus ensuring more uniformity in reporting procedures. If a ship report was known to be from a buoy (from the "deck" number in the COADS data) it was discarded. Any report that had no cloud information (N=/) was discarded.

In 1982 WMO introduced several coding procedure changes (WMO, 1988). One of these changes now instructs observers to set ww=/ if present weather was either "not available" or "observed phenomena were not of significance" (ww codes 00-03 are considered to represent phenomena without significance). The present weather indicator, I_x , is used to distinguish these cases. Land station reports with I_x values of 4, 5 or 6 signify automatic weather stations and were discarded. Reports with $I_x=3$ (data not available) were also discarded because without ww it is not possible to interpret cases of N=9 (see Warren et al., 1986) or to evaluate the occurrence of precipitation. $I_x=2$ indicates that observed phenomena were not of significance, while I_x is coded as "1" when ww is given. Occasionally $I_x=1$ when ww=/. These inconsistent reports were also discarded.

Examination of the NMC data set showed that while land station reports conformed to this new coding procedure almost immediately, ship reports did not incorporate I_x coding consistently until 1985. The COADS data set does not even contain I_x . Thus some ship reports that should be discarded on the basis of I_x were kept. At the horizontal dashed line in Figure 1 there were 125 million land reports and 15.8 million ship reports remaining. The discard fractions below the line are fractions of these numbers.

If the sky was obscured due to fog (1.1% land, 2.5% ship), thunderstorms (0.05% land, 0.17% ship), or rain/snow (0.4% land, 1.1% ship), the sky was considered to be overcast (N=8). This source of "cloudiness" contributed about 1% to the total cloud cover globally, and much more in some locations and seasons (Hahn et al., 1992).

Other data consistency checks are indicated in the figure. The final one tests whether the reported latitude and longitude of a land station puts the station on water (rare) or whether reported latitude and longitude of a ship puts the ship on land (1.3%). The reports that survive these tests (124.2 million for land and 14.4 million for ships) are used to compute total cloud cover and the frequencies of occurrence of clear sky, fog, and precipitation. Cloud types were not analyzed further in this study.

2) Determination of Cloudiness at Night.

The ability of surface observers to adequately detect clouds at night has been questioned for many years (e.g. Riehl, 1947; Schneider et al., 1989). In an attempt to find a practical solution to this "night-detection-bias", the authors (Hahn et al., 1994) analyzed ten years of nighttime data for the zone 0-50°N and plotted reported cloud cover as a function of the illumination due to moonlight. The illuminance function used by the authors depends on the phase and altitude of the moon and on the distance of the moon from the earth. It was found that the amount of total cloud reported at night increased as the illuminance of the moon increased up to a certain threshold, after which reported

cloud amounts leveled off. This threshold is referred to as "the illuminance criterion" and corresponds to the light produced by the twilight sun at an altitude of about 9 degrees below the horizon. Thus the illuminance criterion is met when either the sun is at an altitude greater than -9° or the position of the moon is such that its illuminance exceeds the threshold. These conditions can be determined for each report with the use of an ephemeris and the latitude, longitude, and time of the report.

By using only reports for which the illuminance of the moon (or sun) exceeded the threshold illuminance, we can obtain more reliable estimates of nighttime cloudiness than have been previously obtained from surface observations. Application of the illuminance criterion increases the computed global average total cloudiness at night by about 4% and thus increases the daily average cloudiness by about 2%. There is also a significant effect on computed diurnal cycles which will be demonstrated in Section 3.

This illuminance criterion was applied in the analyses of total cloud cover and clear-sky frequency archived here, but not for fog and precipitation whose detection does not depend on illumination. (For comparative purposes, some analyses of total cloud and clear sky were also performed utilizing all observations as described in Section 3.) Application of the illuminance criterion caused 27% of the land reports and 24% of the ship reports to be discarded, leaving 90.4 million reports for land and 10.9 million reports from ships.

3) Averaging Methods.

An average for a synoptic hour, or for daytime or nighttime only, was obtained simply by averaging all the contributing reports, whether for a single year or a multi-year average. Because many nighttime reports are discarded due to the illuminance criterion, there are far fewer contributing reports at night than during the daytime. Therefore, to obtain the "daily" average, daytime and nighttime averages are first determined separately and then averaged together. For this purpose, daytime is considered to be 06-18 local time (determined from the longitude at the center of the grid box in which the observation was made) and nighttime is considered to be 18-06 local time. A daily average was obtained by this method if there were at least 50 observations contributing to both the day- and nighttime averages. If there were less than 50 observations were used for the average. Otherwise averages were obtained by using all available observations, regardless of time of day. This method was applied uniformly over the globe, even though the method loses significance near the poles. (The poles themselves were considered to be on Greenwich Mean Time.) The particular method used in computing an average is coded in the data record which is described in Section 3.

It should be noted that in a single month at a single point on earth the moon will be above the horizon at night only for about 2 weeks. Thus a nighttime average for a single month, when the illuminance criterion has been applied, will not be fully representative of that month. Longer term averages will be statistically more reliable. For this reason, monthly mean daily averages are not provided in this data archive, although the data for obtaining them are available in the "monthly means by synoptic hour" that are provided (Section 3).

C. Grid Sizes

The globe was divided into grid boxes for which the various cloud quantities were computed. The three grid sizes used in these analyses are, nominally: $2.5^{\circ} \times 2.5^{\circ}$, $5^{\circ} \times 5^{\circ}$, and $10^{\circ} \times 20^{\circ}$ latitude x longitude. Because the area contained within a $5x5^{\circ}$ box, for example, decreases with

increasing latitude, boxes poleward of 50° latitude were made to encompass a wider longitude range such as $5x10^{\circ}$ or $5x20^{\circ}$, etc. A "c" is used to symbolize this condensation or contraction. Thus 5x5c (or 5c for short) means $5x5^{\circ}$ between 50N and 50S but a larger longitude width poleward of 50° latitude. The three grid sizes used are described in Table 3.

Each grid box is assigned a number. The numbering goes from west to east (beginning with the Greenwich Meridian) and north to south. The west and south borders of a box are considered to be within the box (90°N is also considered to be within box 1). The latitude and longitude at the center of each numbered box for each grid are given in this archive (Section 3).

The 5c grid is used for most analyses over the ocean and for some land analyses. The 10c grid is used for some ocean analyses because relatively sparse ocean data make some analyses at the smaller grid size unreliable. The 2c grid is used only for analyses over land where finer resolution is practical.

3. CONTENTS AND ORGANIZATION OF THE DATA ARCHIVE

A. General

The data are divided into 15 files, numbered 2 to 16 as shown in Table 4. File 1 is a brief documentation of the archive, containing excerpts from this report. The organization of data into files is based on similarity of content and data format. Total cloud data are generally separated from weather type data. Land and ocean data are generally in separate files as well. There are many grid boxes that contain both land and ocean, and two separate values are retained in this way. The user can combine the two if desired, although land and ocean values are given at different grid scales making suitable averaging necessary. File 3 contains land and ocean data merged on a 5c grid for selected long-term averages (see below). The files listed with the same group cluster name would logically belong within the same file. However, monthly averages by synoptic hour require so much storage space that they are placed in separate files.

A detailed breakdown of the contents of each data file is given in Table 5. Each data file contains a series of "map groups", each of which consists of gridded data for total cloud or weather type averages for a particular season or year or time of day or for grid information (File 2) as indicated in the table. A map group is made up of the data records for a number of grid boxes over the globe and a header record which identifies the group:

Header record identifying map group Data record for first reported box Data record for second reported box etc. for number of boxes specified in header.

This pattern is repeated throughout each file in the order indicated in Table 5. Data record formats shown in Table 6 and the header record described in Table 7 are discussed in the next section.

The number of data records within a map group depends on the grid size and whether it is for land or ocean. Since there would be no land data in an ocean-only grid box (and vice versa), data records for such boxes are uniformly not written. (Box numbers based on the full grid are provided in the data record itself.) The numbers of boxes given within each type of map group are listed in a footnote to Table 5 (and are coded in the header record). Thus, in File 6, for example, each ocean 5c map group contains 1494 logical records - a header record and 1493 data records, while a land 5c map group in File 4 contains a total of 862 logical records. While there are actually 934 5c boxes with land fractions greater than 0.0001 (and 27 additional boxes with reporting stations on small islands), only 861 boxes have data for the period analyzed here and only those boxes are archived. Similarly there are 3027 2c boxes with land fractions >0.0001 (and 48 additional boxes with reporting stations on small islands) but only 2309 boxes have data. The 10c grid contains so few boxes that it is convenient to retain all 230 boxes, including the 16 land-only boxes. In file 3, where land and ocean are combined on a 5c grid, all 1820 boxes are retained.

B. Details of Organization

The use of Table 5, along with Tables 6 and 7, should enable the user to find any desired quantity, once a few conventions are understood. Abbreviations used are listed alphabetically in Table 8.

1) Map Groups and Data Formats.

Each data file shown in Table 5 is a series of map groups which are numbered consecutively within each group cluster. Each group contains the data relevant to the cloud or weather type quantities listed under the contents heading. These data are given for each reported grid box according to the indicated data format which is described in Table 6. For example, group 2 in File 6 contains data relevant to mean seasonal (DJF, 1982-91) total cloud cover over ocean on a 5c grid. These data are organized according to format 22. Table 6 shows that format 22 specifies the box number, the number of observations, the average amount of total cloud (given to hundredths of a percent), the standard deviation of the observations contributing to the average (given to tenths of a percent), and indicator telling whether contributing observations were from daytime, nighttime, or both (see IDN in Table 8), an indicator telling whether the observations were from land stations or ships, and the number of seasons contributing to the average (relevant only for annual averages).

Data format numbers are given as 2-digit integers. The tens digit distinguishes 5 data classes as shown in Table 6. The units digit is used to distinguish some small difference in the meaning of a variable represented. Format 40 is used to distinguish the fact that the phase of the annual harmonic is given in units of months as opposed to hour for the diurnal harmonic in formats 41 and 42. The differences between formats 41 and 42 (as well as 51 and 52) are simply that the data variables refer to amount or frequency, respectively. While these distinctions (and that between formats 22 and 32) are not essential in this "Total Cloud Edition", these numbers are retained to be consistent with our previous archive (Hahn et al., 1988) and a possible future archive containing cloud type data.

The order in which the groups follow each other, with respect to season, time of day, year or weather type, can also be determined from Table 5. Where there are simply 4 seasons (or 12 months) as with File 4 groups 2-5 (or 42-53), all the boxes for the first season (or month) are followed by the next group header and all the boxes for the second season (or month) and so on. The order in which the seasons are given is DJF, MAM, JJA, SON; months are given in the order Dec, Jan, Feb, . . . Nov. In cases such as for File 4 groups 10-41 or 98-137 where more than one time or year is given for each season, the convention adopted is to increment the parameter listed first while holding the parameter listed second constant. Thus the order for groups 10-41 would be 8 synoptic hours (in order of increasing hour) for DJF, then 8 synoptic hours for MAM, etc. The order for groups 98-137 would be 4 seasons for 1982, 4 seasons for 1983, etc. Thus the individual seasons follow each other

chronologically. The order in which weather type groups (as in File 8) follow each other is the numerical order of the numeric codes shown in Table 7. Using the convention of incrementing the leftmost group parameter first, it can be determined, for example, that the group number for precipitation frequency over land for MAM 1982-91 at 03 GMT is 69.

2) Group Headers.

The first record in each map group is a header record which identifies the group. The format of this header record is shown in Table 7. The first parameter of the header record gives the map group number. These numbers have no special significance other than that they run sequentially through a group cluster (Tables 4 and 5) and may aid in locating or identifying a map group.

The next three parameters specify the number of boxes reported in the group (the number of records to be read before reaching the next map group; this number may be less than the total number of boxes in a grid as discussed above), the grid size of the boxes, and whether the data are for land or ocean or both. This latter parameter, LO, differs from the parameter LOB in Table 6 in that LO specifies the *intent* of the map group while LOB indicates the *actual* condition for a particular box.

The IMOON parameter indicates whether the illuminance criterion was applied in the analysis of the data for the group. The last 5 parameters in the group header indicate the year, season (or month), time of day, cloud or weather type to which the data refer, and the data format.

Even without the map group number, the other 9 parameters together uniquely define each map group. The map group headers, along with example data records, that correspond to the examples given in the last section from Files 6 and 8 are:

| 21493 520829141-1 122 | 692309 211829142 3 332 |
|-----------------------------|------------------------------|
| 1 (first data record) | 24 (first data record) |
| 1 381 5182 7435 297 32-9 | 1444 50 200 -9 21-9 |
| 1809 {last data record} | 7290 {last data record}. |

The first example is for daily-average total cloud cover over the ocean with the illuminance criterion applied for DJF, 1982-91. There are 1493 data records in this 5c map group. The first data record is for box 1 and the last is for box 1809. The example box 381 (in the eastern North Pacific) has 5182 observations with an average of 74.35% total cloud cover. The standard deviation of the observations is 29.7%. The daily average was obtained by averaging daytime and nighttime averages. Only ship data contributed. The "-9" signifies that no value is reported for the last variable, NSN (see *The Missing Value Code* on page 15).

The second example is for the frequency of occurrence of precipitation over land at 03 GMT for MAM, 1982-91. The illuminance criterion was not applied. There are 2309 data records in this 2c map group. The first data record is for box 24 and the last is for box 7290. The example box 1444 (in the western United States) had only 50 observations during this time, giving an average precipitation frequency of 2.00%. The standard deviation is not given. These data are for nighttime over land.

C. Details of Contents

All data on this tape were written as integers. Floating point quantities were multiplied by a power of 10 and rounded off to give an integer. When read using the specified formats shown in Table 6, the proper floating point values are recovered. This was demonstrated with the examples given in the last section. Cloud cover and frequencies are given as percent. These and the units of other variables defined in the data formats are defined in Table 8.

After discussing the missing value code, details or peculiarities of the contents of each data file will be discussed. Refer to Tables 5, 6 and 7 for references to file contents, format numbers and header coding, respectively. Any non-standard terms not defined in the text can be found in Tables 1, 2, 3 or 8.

1) The Missing Value Code.

Any data variable for which no value is reported is assigned the "missing value code", which was chosen to be -9. Thus, when reading in the various floating point notations, the actual value obtained may vary but will always be less than 0. The trend (File 16, formats 51 & 52) is the only data variable for which a negative value is valid. Thus for trends the missing value code should be considered to be NYRS=0. Note that any time NOBS is zero, data variables such as AMT, FQ or SD will be assigned the missing value code, but it is possible for data variables, such as SD, to be assigned the missing value code even when NOBS is not zero.

2) File 2: Grid Information; format 10.

The three groups in this file contain data related to the grids used for dividing the globe (see Table 3). The parameters YEAR, SN, TIME and TYPE in the group header are set to -9. Inclusion of the box number in this data format is redundant since here all boxes are reported and data records are in box number order. The latitude (90 to -90 for N to S) and longitude (0 to 360E) of a box center are given to two decimal places. Since the gridded data in all subsequent files are identified only by box number, the information here allows those data to be located on a map. The inverse relation (converting latitude and longitude to box number) can be achieved with a simple mathematical relationship (Hahn et al., 1988). The fraction of each grid box that is land is given to four decimal places. Here "land" means "not ocean" since lakes and ice shelves are counted as land. The method for determining these fractions and a map for the 5c grid are given in Warren et al. (1986). Ocean fraction is 1 - land fraction.

The number of land stations in a 2c box was approximated by taking the number of observations over the 10-year period for a single season (MAM) for either 00 or 12Z, whichever was daytime for a box, and dividing by 10 (for the number of years) and by 3 (for the number of months in a season) to get the average number of reports per month at a single reporting time. If each station always reported, there should then be 30 reports per station. Since station reports are sometimes missing, the above number was divided by 25 to obtain an approximate value for the number of stations. This number may be of value in estimating the reliability or representativeness of data within a box. NLSTA is set to -9 in the 5c and 10c data records.

3) File 3: Land and Ocean Combined; formats 22,32.

This is the only file in which land and ocean values were merged onto a single grid, and this was done only for 10-year mean values (monthly, seasonal and annual). An average (total cloud cover or weather type frequency), for any grid box for which both land and ocean values contributed, was determined by weighting the contributing land and ocean values by their respective fractional area within the box. Only averages made from 100 or more observations were allowed to contribute. The variables SD and IDN (and NSN for seasonal and monthly averages) were set to -9 in the data record. LOB indicates whether land, ocean, both or neither contributed to the box. For the annual averages, NSN is the sum of the number of seasons that contributed to the land and ocean annual averages before merging, and so can have values 0 to 8 (in this file, -9 is used rather than 0). If NSN is 3 to 7 and LOB is 3, it cannot be known how many seasons were contributed by land or ocean without examining the annual map groups for land and ocean separately in their respective files.

NOBS is the sum of the number of observations contributed by land and ocean. For annual averages on a 5c grid, it is possible for NOBS to be greater than 9999999 (the maximum allowed in the 16 format) since some boxes, notably in Europe, have a large number of land stations. NOBS in such cases was set to 9999999. (The actual number can be retrieved, if desired, by adding up the number of observations in the contributing boxes and seasons given in the other files.)

Figures 2-5 are provided to illustrate some of the information available in this archive and serve as examples against which user output can be checked. The first map group of File 3 contains the data for the global distribution of annual average total cloud cover for the 1982-91 period with the illuminance criterion applied. This is shown in Figure 2a. The global distribution of annual average precipitation frequency (from all observations), a quantity not provided in our previous archive, is given in Figure 2b. These data are contained in map group 3 of File 3. Values are printed in these two figures only where there are at least 100 observations contributing.

4) Files 4-7: Total Cloud Cover; format 22.

Total cloud cover is given in percent (AMT in format 22). Ten-year means for daily average annual, seasonal and monthly total cloud cover are given on the 2c grid for land and on the 5c grid for ocean. Daytime means are given seasonally as well. Because some parts of the southern oceans are poorly sampled (see, for example, Figure 2a), mean seasonal values over the ocean are also given on the 10c grid. It is the 10c grid that is used for the ocean mean seasonal averages by synoptic hour, which are utilized in the diurnal cycle analysis given in File 16. Since land stations are at fixed locations, use of a smaller grid size does not pose the problem that it does for the ocean.

Since previous climatologies, such as our own (Warren et al., 1986; 1988), did not utilize the illuminance criterion, a discontinuity of about 2% would occur when comparing the present with the previous data. Therefore 10-year mean seasonal and yearly seasonal mean values were also computed using all observations (File 4 map groups 54-97 and File 6 map groups 58-101). These data also make it possible to analyze the effects of the illuminance criterion in the present data set. Grid sizes of 5c and 10c for land and ocean, respectively, were selected for ease of comparison with our previous data set (Hahn et al., 1988).

Seasonal means are given for daytime and nighttime values as well as for the daily averages to aid in analysis of possible differences in trends between day and night. Seasonal means for land are given at 5c as well as 2c to make merging with ocean values easier if desired.

The most basic units provided in this data set are the monthly means by synoptic hour. From these, all other averages given, and some not given, can be reconstructed. Since it requires 960 map groups for 10 years of 8 synoptic hours monthly, this unit is provided in a file separate from the rest of the group cluster. The IDN variable in the data record labels each GMT synoptic hour for each box as day or night.

The mean annual total cloud for a grid box was computed by averaging the mean seasonal values of the seasons with 100 or more observations. The number of seasons contributing to the annual average is entered in the NSN variable and may vary from 0 to 4. Note that if NSN is 1, as may be true for ocean boxes near the poles, the reported value may not be representative of the true annual value. NOBS is the sum of the number of observations in the contributing seasons. SD and IDN are set to -9. For seasonal and monthly averages, only NSN was uniformly set to -9.

5) Files 8-15: Weather Types; format 32.

Most of the comments made in the last section apply equally well here. A few differences are noted. Percent frequencies of occurrence of clear sky, precipitation and fog are given in these files. The SD variable in the data record is assigned the missing value code. Precipitation and fog are always computed from all observations and so do not have to be repeated in the "all" map groups. However, since fog is given on the 2c grid for land, it is repeated at 5c for ease of comparison with previous data sets. Daytime and nighttime seasonal means are not given here (but could be reconstructed from the monthly means by synoptic hour if desired). This is also true for seasonal means at 5c for land. Seasonal means for the ocean are given on the 10c grid.

6) File 16: Harmonics, Interannual Variations and Trends; formats 40-42, 51-52.

The unifying feature of the contents of this file is that these are quantities derived from data already given in the archive. Separate land and ocean values are included and two different format types are used to accommodate the harmonic analyses on the one hand and the interannual variations on the other.

The phase and amplitude of the <u>annual harmonic</u> of total cloud cover (or of the frequency of occurrence of a weather type) were computed from the mean monthly values if all 12 months had 100 or more observations. (NT in format 40 always gives the number of months with 100 observations but the other variables were only computed if NT=12.) The amplitude reported is the absolute amplitude so that, for example, if the mean value for a particular cloud amount is 25% and the maximum of the fitted cycle is 30% then the amplitude is reported as 5% (rather than 20% which would be the normalized amplitude). The phase is a numeric value that corresponds to a month such that 1.0 is the middle of January, 2.0 is the middle of February, etc. Phase values reported range from 0.5 to less than 12.5. The value 0.0 (rather than -9) was used for PHASE in cases in which the amplitude was exactly zero (thus distinguishing these from "missing value" cases). AVG is the average of the 12 months used in the analysis and may differ somewhat from the annual values given in the other files

because of the different averaging methods. VAF is the percent of the variance accounted for by the amplitude of the annual harmonic.

To exemplify some features of the annual harmonic, figures 3a-c give the geographic distribution of the phase of the annual harmonic for total cloud cover, precipitation frequency and fog frequency, respectively, from the ocean map groups 21, 23 and 24 of File 16. (A phase of "0", common for fog in Figure 3c, indicates that the amplitude is exactly zero.) It is interesting to note that maximum total cloud cover occurs during the summer months in the North Pacific (Figure 3a), while precipitation frequency reaches maximum values during the winter months (Figure 3b). Figure 3c shows that fog is at a maximum in this region during the summer. The amplitude of the annual cycle for fog (available in the data record but not shown here) reaches 10-20% in the western North Pacific, making a significant contribution to the computed total cloud cover in this region during the summer. By comparison, amplitudes for the fog annual cycle are generally near zero between 30N and 50S over the ocean.

The <u>diurnal harmonic</u> (formats 41-42) was computed from the mean seasonal by-synoptic-hour values if there were 8 or 4 evenly spaced hours with 100 or more observations. If these conditions were met then NT= 8 or 4, otherwise NT was set to 0 and the other variables were set to -9. The amplitude reported is the absolute amplitude (not the normalized amplitude). The phase is the hour of day (mean solar time of the box center) and may range from 0 to less than 24. Since zero is a valid phase here, PHASE was set to -9 for cases in which the amplitude was exactly zero. AVG is the average of the 8 or 4 hours used in the analysis and may differ somewhat from the seasonal values given in the other files because of the different averaging methods. VAF is the percent of the variance accounted for by the amplitude of the diurnal harmonic.

As might be expected, the utilization of the illuminance criterion had a profound effect on the outcome of the diurnal cycle analysis. The geographic distribution of the amplitude and phase of the diurnal harmonic for total cloud cover over the oceans is shown on a 10c grid between 60N and 60S for four seasons in Figures 4a-d. (The phase is printed in these figures only where the amplitude is not zero.) The effect of the illuminance criterion is apparent when comparing these figures to Maps 114-115 of Warren et al. (1988) which show near-noon phases dominating in the diurnal analysis presented for 1954-1983 data without application of the illuminance criterion. For example, for JJA, in Figure 4c, a band of midnight to 5 AM phases evident in the eastern Pacific replaces 4 AM to early afternoon phases in that same region shown in Map 115b of Warren et al. Early afternoon phases are still evident in the western North Pacific and the western North Atlantic, however.

Diurnal cycle analysis for land data is given on the 2c grid. Since it is difficult to display the entire 2c grid, examples are given for two selected mid-latitude regions in Figure 5. Figure 5a shows the diurnal cycle of total cloud cover for part of Asia for DJF. Here diurnal sampling tends to be 8 times per day and there tend to be many reporting stations, particularly in China in the southeast portion of the region. While phase differences between these data and those of Warren et al. (1986, Maps 18-19) tend not to be as dramatic as those over the ocean, the morning phases on the northwest and southeast portions of Figure 5a contrast with those of Warren et al. Where the phases are comparable (and near noon), however, the amplitudes tend to be smaller when the illuminance criterion is applied.

Figure 5b shows the diurnal cycle analysis for JJA for the region of North America that covers most of the United States, where diurnal sampling tends to be 4 times per day. In the eastern portion of the region phases tend to have early afternoon values, in agreement with those of Warren et al.

(1986, Maps 22-23), while in the western portion the phases are more variable. This illustrates another feature of the present data set. The $2.5x2.5^{\circ}$ resolution is capable of resolving features that are missed at $5x5^{\circ}$, such as the band of late night to early morning phases evident in the central plains of the United States.

The last map groups in this file contain the results of the analysis of <u>interannual variations and</u> <u>trends.</u> For each season, an individual year contributed to the computation of IAV, TRND and UNC (formats 51-52) for a grid box if there were at least 100 observations. The number of years contributing is given in the variable NYRS. SPAN gives the number of years between the first and last years contributing, including the first and last years. If NYRS (also SPAN) is zero, IAV, TRND and UNC are assigned the value -9. IAV is the standard deviation of the contributing yearly values about the multi-year mean. TRND is the slope of the straight line which was fit to the data points by least-squares analysis and is given in units of percent cloud amount (or percent frequency) per year. UNC is the uncertainty of the slope (Bevington, 1969, page 113) in the same units.

4. HOW TO OBTAIN THE DATA

This documentation and the data described herein are available from:

Carbon Dioxide Information Analysis Center Oak Ridge National Laboratory Post Office Box 2008 Oak Ridge, TN 37831-6335, U.S.A. Telephone (615) 574-3645

or

Data Support Section National Center for Atmospheric Research Boulder, CO 80307, U.S.A. Telephone (303) 497-1215.

The following <u>citation</u> should be used for referencing this archive and/or this documentation report:

Table 5 continued. Data Organization

* Non-standard terms are defined in Table 8. Briefly:

TC= total cloud; WT= "weather types" (clear sky, precipitation, fog).

** Illuminance criterion applied to total cloud and clear sky unless "all" specified. Ppt and fog always determined from all observations.

Grid sizes are described in Table 3.

Number of boxes archived for 2c land = 2309, for 5c land = 861, for 5c ocean = 1493, for 5c land+ocean = 1820, and for 10c ocean = 230

Months are given in the order: Dec, Jan, Feb,...Nov.

If "2types" are specified, they are clear sky and fog.

If "1type" is specified, it is clear sky.

Convention for the order of groups in a multigroup listing is:

increment left group qualifier while holding right qualifier constant.

Table 7. Map Group Header Record Format and Codes* (Total Cloud Edition)

erms are defined in Tables 3 & 8.

| Term | Meaning and description |
|------------|---|
| AMP | Absolute amplitude of harmonic (not normalized). |
| AMT | Average amount of cloud cover, given in percent. |
| ann | Annual. |
| AVG | Average AMT or FQ. In formats 40-42 it is the average of NT values. |
| BOX | Box number specific to grid size. See Table 3. |
| Cb | Cumulonimbus cloud. |
| CLAT | Center latitude of grid box. Values +90 to -90 for N to S. |
| CLON | Center longitude of grid box. Values 0 to 360 East. |
| day (time) | Local time 06-18. |
| DJF | December (of the previous year), January, February. |
| FMT | Data format number (see Table 6). |
| FQ | Frequency of occurrence; given in percent. |
| FRL | Fraction (0. to 1.0000) of area in grid box that is land. |
| GMT | Greenwich Mean Time. |
| IAV | Interannual variation (standard deviation of contributing year averages). |
| IDN | Indicates whether reports contributing to box average were from day only (=1), night only (=2), both (=3) or had less than minimum observations (=4) {see Section 2B3}. |
| IMOON | Indicator for application of the illuminance criterion: 0= criterion applied ("Moon"), 1= not applied ("All"). |
| JJA | June, July, August. |
| hrs | Hours. |
| lat | Latitude. |
| LO | Indicator that group data are intended to be for land (=1), ocean (=2), or both (=3). |
| LOB | Indicator that box data were from land only (=1), ocean only (=2), both (=3), or no data (=0). |
| lon | Longitude. |

Table 8. Terms and Abbreviations Used

| Table 8 continued. Te | erms and Abbreviations Used |
|-----------------------|--|
| Term | Meaning and description |
| MAM | March, April, May. |
| MGRP | Map group number. Increments serially through group cluster (see Tables 4 & 5). |
| missing value code | The integer -9. Imerted in data record where no legitimate value is reported. (In formats 51-52 use NYRS=0 for missing value code.) |
| night (time) | Local time 18-06. |
| NLSTA | Approximate average number of land stations reporting in a 2c grid box. |
| NOBS | Number of observations. |
| Ns | Nimbostratus cloud. |
| NSN | Number of seasons contributing to annual average. |
| NT | Number of synoptic hours used (4 or 8) for diurnal harmonic analysis or number of months used (12) for annual harmonic analysis. |
| NYRS | Number of years contributing to trends and IAV. |
| mean seasonal | Long-term average; average over several years for season. |
| Mns | Months. |
| PHASE | Phase of first harmonic. Diurnal: 0-24 hours mean solar time of box center (-9 if AMP=0). Annual: month (0.5 -12.4 [1.0 = middle of January, etc.]; 0 if AMP=0). |
| SD | Standard deviation; in units of variable (not normalized). |
| seasonal mean | Average for an individual year for a particular season. |
| SIZE | Grid box size indicator. |
| SN | Season or month indicator. |
| sns | Seasons (DJF, MAM, JJA, SON). |
| SON | September, October, November. |
| SPAN | Span of years contributing to trend and IAV (includes first and last years contributing). |
| TIME | Time of day for which group data apply. |
| TRND | Trend. Slope of least-squares fit (change in average/yr). |

| Meaning and description |
|--|
| Cloud or weather type code. |
| Uncertainty of trend line; same units as TRND. |
| Percent variance accounted for by the first harmonic. |
| Year or years for which group data apply. Coded as 19yr for single years where yr gives the last 2 digits of the year, and as yfyl for multi-year averages where yf=yr of the first year and yl=yr of the last year of the period of record. |
| Years. |
| |

•--

Figure 1. Flow chart of data selection and checking. Abbreviations are defined in Tables 1, 2 & 8. (Discard fractions given in order "land, ship" where needed). See text for discussion.
