Chapter 2 Combustion-Based Transportation in a Carbon-Constrained World— A Review

Tamour Javed, Ahfaz Ahmed, Vallinayagam Raman, Awad B. S. Alquaity and Bengt Johansson

Abstract The transportation sector accounts for around a quarter of global CO₂ 7 emissions and is powered predominantly by fossil-derived fuels. The regulatory 8 framework is evolving globally to more stringent requirements for fuel efficiency 9 and CO₂ emissions, forcing the OEMs to adopt advanced powertrain technologies. 10 Such changes are more evident in the light-duty road transportation sector com-11 pared to the heavy-duty road, marine and air transportation sectors. Here, a holistic 12 review of the current and prospective regulations targeted at curbing transportation-13 based CO₂ emissions is presented. For road transport, these include various gov-14 ernment- and state-level policy initiatives such as the Corporate Average Fuel 15 Economy (CAFE) and CO₂ emission standards and the zero emission mandates. 16 For marine and aviation sectors, these include the International Maritime 17 Organization (IMO) and the International Civil Aviation Organization (ICAO) 18 regulations and aspirations targeted at reducing the CO₂ footprint. The compliance 19 options for these regulations are evaluated using a combination of fuels, engines, 20 and hybridization in each transportation sector. Furthermore, a brief overview of 21 how OEMs are working toward achieving these targets is presented. An overview 22 of several advanced spark and compression ignition engine technologies with the 23 potential to improve the fuel economy and CO₂ emissions is presented. Finally, an 24 overview of major disruptions that are changing the road-based transportation is 25 presented and a balanced life cycle based policy approach is advocated. 26

30 **2.1 Introduction**

31 2.1.1 History

Combustion of fuels has been a dominant source of energy for mankind since ages. 32 In primitive times, wood was the major fuel used for heating, lighting, and cooking 33 purposes. As mankind's understanding of their surroundings grew, the focus shifted 34 to an improved version of fuels such as coal, marking the beginnings of the fossil 35 fuel era (Morris 2015). Coal-offered significant advantages over wood such as 36 higher energy density, better flammability, etc., making it a fuel of choice for 37 heating, lighting, and even powering mobility. Locomotives with coal-powered 38 steam engines were introduced in the eighteenth century and became popular 39 (McNeil 2002). Arguably, a paradigm shift in mobility came along when Nikolaus 40 Otto patented his 4-stroke engine in 1876 (Wayne 1970) along with Gottlieb 41 Daimler and Wilhelm Maybach, which used one of the light fractions from crude 42 oil distillation as fuel (Morris 2015). Henry Ford eventually reinforced the signif-43 icance of this discovery in 1908 when he introduced the first mass-produced 44 affordable vehicle, Model-T (Wayne 1970). This innovation, along with other 45 similar developments in the European markets (Dutton 2006), revolutionized the 46 personal mobility sector leading to its wide acceptance among common people. 47 Despite enabling freedom of movement for the mass population, the early vehicles 48 were riddled with issues such as poor fuel efficiency, low power density, and were 49 very high on carbon emissions (Dutton 2006). These shortcomings became more 50 evident (De Groot 1996; Tushman 1997; Kline and Rosenberg 2009) when the 51 World Wars broke out in Europe and to support the war effort, fuel efficient and 52 high powered vehicles were needed. One inhibitor in improving the fuel efficiency 53 of these engines was their low compression ratio, which was limited by engine 54 knock (Seyferth 2003). Fuels at that time had lower octane numbers because of 55 limited advancement in refinery processes (Splitter et al. 2016) such as catalytic 56 reforming, cracking, etc. Amid attempts on engine and fuel improvement in the 57 1920s, a young engineer Thomas Midgley and his associates came up with the 58 suggestion of blending small quantities of Tetra Ethyl Lead (TEL) to the gasoline to 59 increase its knock resistance and hence allowing engines to deliver higher power 60 and better efficiency in the process. However, due to health and environmental 61 impacts of TEL, it was phased out in the 1970s around major parts of the world, 62 thereby affecting the automotive efficiency adversely (Splitter et al. 2016). Soon 63 after, automotive manufacturers started using electronic fuel injection system and 64 engine management software, which revived engines' performance to TEL levels. 65

2 Combustion-Based Transportation in a Carbon-...

The foci of the automotive industry till this point were to improve fuel efficiency and power density while the emissions were of little concern.

The obliviousness toward increasing pollutant emissions from vehicles led to the 68 constitution of California Air Resources Board (CARB) in California (United 69 States) in 1967 (Hanemann 2008). This board established regulations on vehicular 70 emissions paving the way for Environmental Protection Agency (EPA) in the US 71 and EU emission standards in the Europe and subsequently around the world. These 72 regulatory bodies acted primarily to address the poor air quality in the developed 73 parts of the world. However, in the same context, another significant event took 74 place in 1966. World Meteorological Organization (WMO) (a body within United 75 Nations) published a report (Mitchell et al. 1966) on climate change which referred 76 to human activity as a predominant reason causing the alteration of natural course 77 of Earth's climate regulating processes. These findings were later followed by 78 the commencement of the United Nations Climate Change Conferences under 79 the United Nations Framework Convention on Climate Change (UNFCC) (1992). 80 The main goal of the UNFCC is to "stabilize greenhouse gas concentrations in the 81 atmosphere at a level that would prevent dangerous anthropogenic interference with 82 the climate system." 83

Since then, two meetings of UNFCC have had a significant impact in shaping 84 global climate change policies. In 1997, during Kyoto summit (UNFCC 1992), it 85 was decided that the participating states will strive to reduce greenhouse gas 86 emissions based on the scientific consensus that global warming is occurring and it 87 is extremely likely due to anthropogenic CO₂ emissions. During the second meeting 88 in Paris, an agreement to keep the increase in global average temperature to well 89 below 2 °C above pre-industrial levels was reached (UNFCC 2015); in addition to 90 the consensus to limit the increase to 1.5 °C to substantially mitigate the risks 91 associated with climate change. 92

93 2.1.2 Overview

The agreements ratified at these meetings were executed in different versions across 94 major parts of the world with a unified goal to cut down on greenhouse gases 95 promoting climate change. These agreements, however, also led to an increased 96 attention on the emissions from the combustion engines, since automotive sector 97 accounts for around 25% of carbon emissions. To address these implicit demands 98 placed on automotive industries, many new technologies came to forefront 99 including gasoline and diesel direct injection technologies. Although these engine 100 technologies are significantly fuel efficient than conventional engines and facilitate 101 tremendous control of emissions with high power density, major economies around 102 the world still felt the need to take more aggressive steps toward curbing the carbon 103 emissions from the vehicular operation. It eventually led to various announcements 104 during 2016–2018 by many countries including the United Kingdom, China, India, 105 parts of Europe etc. to move away from new sales of passenger vehicles powered by 106

T. Javed et al.

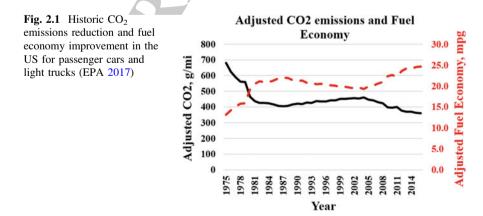

pure internal combustion engine in 2030–2040 timeframe. However, the nature of
 technology to replace internal combustion engines on such a large scale is still
 under debate. In the most likely scenario, it seems that the combustion engines will
 stay for longer than hyped in the popular media, especially in the heavy-duty road
 transport, marine and aviation sectors; however, to address the stricter regulations,
 combustion engines must reinvent themselves.

In this chapter, first, the regulatory framework around the world and their 113 potential directions in response to climate change, including road transport, marine, 114 and aviation sectors are discussed. In Sects. 2.3 and 2.4, the focus is shifted to fuel 115 and engine technologies in various transportation sectors including their historic 116 trends and current efforts to address the market demands and legislations. Further, a 117 brief review of sustainability efforts by major automakers, in the road transport 118 sector, will be provided. Finally, major trends of disruptions in the transportation 119 sector, using examples of important disruption agents, are discussed. In the end, a 120 holistic overview of the entire chapter is presented. 121

122 **2.2 The Regulatory Framework**

2.2.1 Fuel Economy and CO₂ Emission Standards for Road Transport

As a response to climate change, increasing fuel import bills, energy security, and 125 wider impacts of transportation sector on the environment, the regulatory frame-126 work across the world to improve the fuel economy and reduce the CO₂ emissions 127 has evolved over the past 50 years and has become quite stringent. Figure 2.1 128 shows the improvements in CO₂ emissions and fuel economy over the years for 129 passenger cars and light trucks (including pickup trucks, minivans, and SUVs) in 130 the US market. Between 2004 and 2016, the CO₂ emissions and fuel economy have 131 improved by 22 and 28%, respectively (EPA 2017). The data used here is from the 132

2 Combustion-Based Transportation in a Carbon-...

US Environment Protection Agency (EPA)'s adjusted results to better reflect on real-world emissions and fuel economy. The benefits of such regulations are further amplified in the passenger cars sector where adjusted fuel economy has reached a historic high of around 29.1 mpg in 2017. Such improvements are consistent in the rest of the world as well and EU reported a CO_2 reduction of 16% in the 2010–2015 period (Agency EE 2018).

As seen in the figure above, the regulatory framework has evolved significantly 139 over the past decade. Just over a decade ago, only the US, Japan, South Korea, and 140 China had enforced regulations for the CO₂ emissions and fuel economy (Yang and 141 Bandivadekar 2017), while the EU and Canada had expressed their aspirations for 142 such regulations. However, in 2017, such regulations are commonplace and 143 enforced in 80% of the light-duty vehicle market. These standards are too detailed 144 to be summarized here, and only a brief overview of these standards is presented. 145 Table 2.1 shows the fuel economy and CO₂ emissions of passenger cars and light 146 trucks in the US (Transport UDo 2012), the EU (Regulation (EU) No 333 2014; 147 Regulation (EU) No 253 2014), China and India (Yang and Bandiyadekar 2017). In 148 the US, National Highway Traffic Safety Administration (NHTSA) sets the fleet 149 regulations called the Corporate Average Fuel Economy (CAFE) standards since 150 1975, and EPA sets the CO₂ standards since 2007, both standards are harmonized 151 since 2010 for the cars and light-duty trucks of the model year 2012 and beyond. 152

Country/region	Category	Fuel economy and CO ₂ emissions (in year)
US	Cars	36.2 mpg and 225 gCO ₂ /mi (2016)
		55.3 mpg and 143 gCO ₂ /mi (2025)
	Light trucks	28.8 mpg and 298 gCO ₂ /mi (2016)
		39.3 mpg and 204 gCO ₂ /mi (2025)
EU	Cars	130 gCO ₂ /km (2015)
		95 gCO ₂ /km (2021)
		30% CO ₂ reduction compared to 2021 (2030)
	Vans	175 gCO ₂ /km (2017)
		147 gCO ₂ /km (2020)
		30% CO ₂ reduction compared to 2021 (2030)
China	Cars	6.9 L/100 km (2015)
		5 L/100 km (2020)
	Light trucks	6.9 L/100 km (2020)
		-
India	Cars	130 gCO ₂ /km (2017)
		113 gCO ₂ /km (2022)
	Light trucks	_
		-

Table 2.1 Fuel economy and CO₂ emissions of passenger cars and light trucks in the US (Transport UDo 2012), the EU (Regulation (EU) No 333 2014; Regulation (EU) No 253 2014), China (Yang and Bandivadekar 2017) and India (Yang and Bandivadekar 2017)

9	Layout: T1_Standard	Book ID: 472069_1_	En	Book ISBN: 222-22-222-2

T. Javed et al.

The EU legislation sets EU-wide CO₂ emission targets for new cars and commercial 153 vehicles (vans) sold in the EU market. Similar government bodies set the fuel 154 economy and/or CO₂ emissions standards in China, India, and in rest of the world. 155 However, there are some differences in the interpretation of these regulations. First, 156 vehicles are categorized differently in different regions; the maximum Gross 157 Vehicle Weight (GVW) for passenger cars and light-duty trucks in the US is 158 3856 kg, whereas that in the EU, China, and India is 3500 kg (Yang and 159 Bandivadekar 2017). Also, the test cycles used for reporting and certifying these 160 regulations are different. The US regulators use US combined cycle, while the EU. 161 China, and India use New European Driving Cycle (NEDC). EU plans to shift to a 162 worldwide harmonized Light vehicle Test Procedure (WLTP) in the future (Yang 163 and Bandivadekar 2017). Therefore, direct comparison of these standards across 164 various regions should be reported cautiously. However, across the globe, such 165 standards are becoming ever stringent and the CO₂ emissions in most regions are 166 expected to reduce by around 50% by 2025 compared to baseline years (baseline 167 year is different for different regions, see Table 2.1) (Yang and Bandiyadekar 168 2017). Hence, it could be stated that such regulations are successful in reducing the 169 global warming impact of the transportation sector and also bear financial benefits 170 to the consumers and governments. 171

The fuel economy and CO₂ emission standards for the Heavy-Duty Vehicles 172 (HDVs) are still evolving compared to Light-Duty Vehicles (LDVs). The EU only 173 recently (COM//284 (EU) 2018) presented proposals for regulating HDV CO₂ 174 emissions. The EU proposals calls for 15 and 30% reduction in CO₂ emissions, 175 compared to 2019 levels, by 2025 and 2030, respectively, whereas 2030 reduction 176 targets are subjected to review in 2022. Moreover, the EU proposals target only 177 large lorries to start with and plan to widen the regulatory coverage to other HDV's 178 post 2022. In 2016, the US EPA and NHTSA jointly announced the fuel economy 179 and CO₂ emissions phase-II standards for medium- and heavy-duty vehicles 180 through the model year 2027 (Transport UDo 2016). These standards are 181 performance-based and are expected to further improve fuel savings by 25% 182 compared to terminal phase-I respective category baseline. They rely on available 183 and futuristic technological improvements to achieve the targets with a neutral 184 attitude toward different technologies. In China, the stage-II and stage-III standards 185 for HDV fuel consumption are expected to improve the fuel economy by 15% 186 compared to 2015 levels by 2021. Fuel consumption standards for HDVs are also 187 planned to be regulated in phases in India starting in 2018 (phase-I effective from 188 2018, phase-II effective from 2021) (Report I 2017). It is expected that the coverage 189 of fuel economy and CO₂ emissions standards will continue to grow across the 190 world and these standards will continue to evolve towards stricter targets. 191

2 Combustion-Based Transportation in a Carbon-...

¹⁹² 2.2.2 The Zero-Emission Mandates

Several regulatory bodies, at the country/region and state level, have started 193 enforcing regulations that require automakers to directly invest in zero-emissions 194 vehicles (Battery Electric Vehicles (BEVs), Fuel Cell Vehicles (FCVs), etc.). In 195 2016, the US state of California issued the Zero-Emissions Vehicle (ZEV) mandate 196 for passenger cars, light-duty trucks, and medium-duty vehicles (CARB 2016). 197 The ZEV mandate since then has been adopted by nine other US states including 198 Connecticut, Maine, Maryland, Massachusetts, New Jersey, New York, Oregon, 199 Rhode Island, and Vermont. At the core of this mandate, the automakers are required 200 to produce a certain percentage of their vehicles conforming to ZEV standards. This 201 mandate assigns credit based on the zero emitting drive range, e.g., pure ZEVs, i.e., 202 BEVs and FCVs, depending on their driving range. Although the credits for 203 non-ZEVs are lower compared to pure ZEVs, Plug-in Hybrid Vehicles (PHEVs), 204 conventional hybrid vehicles (HEVs), and clean gasoline vehicles qualify for such 205 credits. The mandate allocates "ZEV credits" to the automakers for each vehicle sold 206 and the automakers are required to maintain a certain percentage of ZEV credits of 207 total sales credits year through 2025 (see Table 2.2). For example, an automaker 208 with average sales of 100,000 vehicles between 2014-2016 will require to earn 4500 209 ZEV credits in 2018 (required ZEV credits in 2018 are 4.5%), this does not directly 210 translate into 4500 ZEVs sold as minimum ZEV floor for 2018 is 2.5%. The man-211 ufacturers are allowed to carry over excess credits in a year to subsequent year and 212 can also trade a certain percentage of their credits with other automakers. China 213 introduced a similar mandate in 2017 called the New Energy Vehicle 214 (NEV) mandate (Cui 2018). The NEV mandate calls for each automaker to have a 215 minimum of 10% NEV credits in 2019 and 12% in 2020. The NEV mandate in 216 China also allows the automakers to use their surplus NEV credits for Corporate 217 Average Fuel Consumption (CAFC) compliance, credits trade and credits carry over 218 to next year. The EU has introduced the super-credits system (Regulation (EU) No 219 333/ 2014) for Low CO₂ Emitting Vehicles (LEVs) (below 50 gCO₂/km) vehicles, 220 and plans to incentivize automakers who surpass their share of ZEVs and LEVs 221

Model year	ZEV credit requirement (%)	Minimum ZEV credits
2018	4.5	2
2019	7	4
2020	9.5	6
2021	12	8
2022	14.5	10
2023	17	12
2024	19.5	14
2025 and beyond	22	16

Table 2.2 ZEV credit requirement for the automakers selling vehicles in California and nine other US states (CARB 2016)

9	Layout: T1_Standard	Book ID: 472069_1_	En	Book ISBN: 222-22-222-2

T. Javed et al.

(15% in 2025 and 30% in 2030) with less stringent CO2 targets. Additionally, EU 222 renewable energy directive II (EU-RED II) (COM//0767 final//0382 (COD) 2016), 223 proposes to make it mandatory for the fuel suppliers to include at least 10% 224 renewables by energy in their fuel blends by 2030, where to qualify as renewable, the 225 fuel must provide 70% CO₂ savings compared to fossil fuels in 2021. In short, many 226 regions across the world are expected to adopt similar aggressive mandates for 227 promoting zero-emissions vehicles in the passenger car sector; however, even in 228 presence of such stringent regulations, based on regulators own estimates, the 229 light-duty fleet will still be a mix of ZEV and non-ZEV vehicles by 2050. In reality, 230 the transition toward complete ZEV vehicles will be slow spanning several decades. 231

232 2.2.3 Regulatory Framework for Aviation Sector

Aviation sector accounted for around 11% of oil share in transportation in 2014 and 233 is the fastest growing oil-based transportation sector in terms of energy consump-234 tion (IEA 2017). Due to the global nature of aviation business, the civil aviation 235 sector is regulated globally by UN-chartered International Civil Aviation 236 Organization (ICAO). The ICAO during its 39th general assembly in 2016 has 237 introduced a strategy to reduce CO₂ emissions from the aviation sector (ICAO 238 Resolution 2016). The Carbon Offsetting and Reduction Scheme for International 239 Aviation (CORSIA) proposed in these resolutions call for adopting offset mecha-240 nisms to curb CO₂ emissions in the aviation sector. As a part of this mechanism, all 241 aviation operators that emit more than 10,000 tons of CO₂ per year must report their 242 CO₂ emissions from January 1, 2019 for recording average emissions in the 2019-243 2020 period. The CORSIA mechanism is expected to ensure carbon neutral growth 244 of aviation sector from 2021 by offsetting any CO₂ emissions above the 2020 245 average baseline. The CORSIA mechanism will be rolled out in phases with the 246 pilot phase from 2021 to 2023 and the first phase from 2024 to 2026, both of which 247 are voluntary. The second phase of this mechanism targets 2027–2035 period where 248 all states with international aviation activities in Revenue Tonne Kilometers (RTKs) 249 in the year 2018 above 0.5% of total RTKs or whose cumulative share in the list of 250 States from the highest to the lowest amount of RTKs reaches 90% of total RTKs 251 must participate. Participation in the second phase is voluntary for the Least 252 Developed Countries (LDCs), Small Island Developing States (SIDS), and 253 Landlocked Developing Countries (LLDCs). There are many ways proposed to 254 offset the $\mathbb{C}O_2$ emissions from aviation using CORSIA which includes financing 255 afforestation, wind energy, clean cookstove, methane capture, and other 256 emissions-reducing or avoidance projects. Additionally, technological, operational, 257 and infrastructure measures are proposed for CO_2 reduction in the aviation sector, 258 however, the aviation sector is set to rely heavily on the CORSIA mechanism and 259 hence is expected to be powered by oil-based jet fuels as the primary energy source. 260 Moreover, the NO_x , SO_x , soot emissions, and the noise pollution are receiving 261 increased attention and are expected to be more regulated in future. 262

2 Combustion-Based Transportation in a Carbon-...

263 2.2.4 Regulatory Framework for Marine Sector

Marine industry accounted for around 10% of oil share in transportation in 2014 and 264 this share is expected to rise to 16% by 2050 (IEA 2017). The United Nation's 265 chartered International Maritime Organization (IMO) regulates marine transportation 266 globally. Heavy Fuel Oil (HFO), also known as the bunker fuel, intermediate fuel oil, 267 residual fuel oil, is the primary fuel used in the marine sector. The IMO has imposed 268 Sulphur cap on the HFO limiting the Sulphur content to 0.5% m/m (MARPOL Annex 269 VI), which is a sharp decline from the current Sulphur limits of 3.5% m/m. The new 270 Sulphur regulation will come into effect on January 1, 2020. The Sulphur levels in the 271 HFO for vessels operating in the Emission-Controlled Areas (ECAs), the Baltic Sea 272 area, the North Sea area, the North American area (covering designated coastal areas 273 off the United States and Canada), and the United States Caribbean Sea area (around 274 Puerto Rico and the United States Virgin Islands), are further lower at 0.1% m/m. 275 Therefore, in ECAs, most vessels are already operating on more expensive distillate 276 fuels, which have lower Sulphur content. These regulations apply to both main and 277 auxiliary engines and also to any boilers onboard. Sulphur levels in various fuel oils 278 and commonly used distillates are shown in Table 2.3. 279

The MARPOL Annex VI (2010) also regulates the NO_x emissions for seagoing vessels. The NO_x emission levels are set for ships according to engine maximum operating speed levels and are different for old (Tier I, ships in service before January 1, 2000) and new (Tier II, ships constructed after January 1, 2011) vessels, and the vessels operating in NO_x-ECAs (Tier III, ships constructed after January 1, 2016) (see Fig. 2.2).

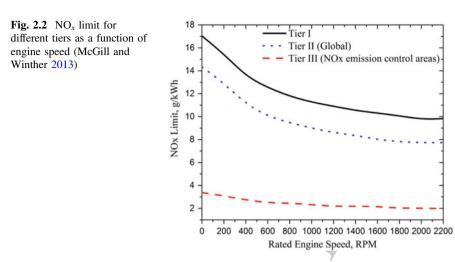

More recently, IMO has in principle agreed on the initial strategy to reduce the 286 CO_2 footprint of the marine sector by 50% compared to 2008 levels by 2050. This 287 CO2 reduction is expected to take into account all facets of the marine sector 288 including technological, operational, and fuel/energy source measures update (ITF 289 2018). The plans may also include market-based offsetting mechanisms for trading 290 CO₂ credits. The IMO plans to revise the agreement by 2023, based on fourth and 291 fifth round of IMO greenhouse gas studies from 2019 to 2022, which would be 292 carried out before drafting any regulations. 293

Common name	ISO name	Typical composition	Typical Sulphur content (%)
Marine Gas Oil (MGO)	DMA	100% distillate	0.1–1.5
Marine Distillate Oil (MDO)	DMB	Distillate with traces of residual oil	0.3–2
Intermediate Fuel Oil 180 (IFO 180)	RME	10% distillate 90% residual oil	2.0-3.5
Intermediate Fuel Oil 380 (IFO 380)	RMG	99% residual oil	3.5

294 2.3 Developments in Transportation Sectors to Meet CO₂ Emission Challenges

16

296 2.3.1 Recent Developments in Light-Duty Sector

There are several ways to meet future emission targets in the light-duty sector 297 (Elgowainy et al. 2018). CO_2 emissions can be mitigated by increasing fuel effi-298 ciency through advanced gasoline and diesel powertrains, hybridization of ICE and 299 battery, using fuels with low C/H ratio, using electric and fuel cell vehicles, etc. 300 Among the various options available, the majority of the mainstream automotive 301 manufacturers are choosing the hybridization and electrification route to achieve the 302 futuristic emission goals (California 2017). Although Battery Electric Vehicles 303 (BEVs) do not pollute at the point of use, the pollution caused during electricity 304 generation and in the production and recycling processes of the batteries is often 305 neglected. Since the current regulatory framework for CO₂ emissions of light-duty 306 vehicles is based on the tank-to-wheel emissions (Thiel et al. 2014), BEVs tend to 307 get an unfair advantage over ICE-driven vehicles. In countries or regions where the 308 electricity generation is predominantly based on fossil fuels, especially coal, BEVs 309 can lead to more GHG emissions as compared to the fossil-fuel-driven vehicles 310 (Huo et al. 2015; Faria et al. 2013; Manzetti and van der Spoel 2015). Additionally, 311 a life cycle inventory of BEVs shows increased risk of human toxicity, eutrophi-312 cation, and metal depletion compared to conventional fossil-fuel-driven vehicles 313 (Hawkins et al. 2013). A more practical issue is the relatively limited driving range, 314 long charging times, short life of battery pack, and lack of charging infrastructure 315 for mainstream BEVs. Improvements in these aspects are an absolute necessity for 316 the widespread adoption of electric vehicles. Therefore, BEVs require more 317 eco-friendly, low-cost, and high energy density batteries to occupy a significant 318 share of the total vehicle fleet. However, despite their current limitations, 319

5	Layout: T1_Standard Book ID: 472069_1_En		En	Book ISBN: 222-22-222-222-2
5	Chapter No.: 2	Date: 11-10-2018	Time: 2:23 pm	Page: 17/34

2 Combustion-Based Transportation in a Carbon-...

automotive manufacturers continue to invest in BEVs relying on future potential for
 improvement in batteries. Additionally, BEVs help the automotive manufacturers in
 meeting the fleet-averaged CO₂ emission regulations as they are considered as
 "Zero-Emissions Vehicles" under the current regulatory framework.

A more viable and practical option is to hybridize ICEs for improved fuel 324 efficiency and reduced CO₂ emissions (Elgowainy et al. 2018). Different hybrid 325 options may be suitable for a different class of vehicles within the light-duty sector 326 and hence diversified options are expected moving forward. Series, parallel, and 327 mix hybrid are the various options available currently and each has their own 328 advantages and challenges. Series-hybrid vehicles offer a promising solution of 329 increasing the fuel efficiency in urban driving conditions by allowing the engine to 330 operate under its optimum condition. In such a scheme, ICE will continue to be the 331 primary energy source for the vehicle. 332

Other options for reducing CO₂ emissions include using fuels with lower carbon 333 to hydrogen ratio. In this case, CNG-driven vehicles become promising due to 334 reduced CO₂ emissions by virtue of their low C/H ratio (Hesterberg et al. 2008). 335 Long-term options include the use of Fuel Cell Vehicles (FCVs) powered by 336 hydrogen or other fuels. Although FCVs have long been touted as the next trans-337 portation solution, their market uptake has been slow and they continue to be part of 338 a niche market. However, some of the mainstream vehicle manufacturers are 330 focusing again on fuel cell vehicles and have invested heavily in their research and 340 development (Toyota 2018). The future of hydrogen produced from fossil sources 341 using carbon capture and renewable hydrogen as a fuel, along with fast refueling 342 and long driving range, makes it an attractive and eco-friendly solution. However, 343 the high cost of fuel cell stack and the lack of hydrogen refueling infrastructure are 344 significant bottlenecks currently. Economies of scale are expected to reduce the 345 price of FCVs, however, this is a typical chicken and egg problem. Following 346 Tesla's lead, Toyota has also shared patents related to various aspects of FCV 347 development to accelerate the growth in this segment (Toyota 2018). Additionally, 348 three major Japanese automakers namely Toyota, Honda, and Nissan are cooper-349 ating to jointly accelerate the introduction of a hydrogen fueling network by sup-350 porting the operation cost and their development. 351

All the aforementioned medium to long-term options require the development of new fueling infrastructure and/or vehicle modifications and are, therefore, time-consuming and costly to implement. To summarize, there are multiple promising options to achieve future emission targets. However, a holistic cradle to grave analysis needs to be conducted to select an appropriate solution on a case-by-case basis rather than implementing a solution, which merely shifts the burden from one life cycle to another.

T. Javed et al.

359 2.3.2 Recent Developments in Heavy-Duty Sector

Despite the availability of transportation modes such as rail and shipping, freight 360 and non-urban public transportation will continue to rely on heavy-duty vehicles 361 such as trucks and buses. It is, therefore, vital that the heavy-duty segment should 362 also be equipped with alternative or advanced combustion engine powertrains to 363 contain the increasing carbon emissions. In heavy-duty segment, there are two 364 major changes, i.e., advancement of the combustion powertrain and electrification. 365 In the rest of this section, both of these worldwide trends have been discussed with 366 regards to the heavy-duty segment. 367

Most of the commercial vehicles around the world use diesel engine as a 368 propulsion system for long-haul road freight truck. To reduce emissions from diesel 369 engine, the thermal efficiency needs to be improved. Initially, when the diesel 370 engine was invented in the 1880s, its efficiency was around 26% and due to 371 continuous improvement in fuel injection systems, engine and piston designs, 372 modern engines exhibit 43-44% thermal efficiency, and it is set to reach 50% by 373 2030 (Lutsey 2018). The US Department of Energy's Super Truck program is one 374 among various initiatives toward improving the overall performance of heavy-duty 375 segment. The first phase of the Super Truck program was started in 2009 and 376 Cummins, Volvo Group, Daimler Trucks, and Peterbilt were tasked with improving 377 the overall freight efficiency by 50%, quantified in ton-miles per gallon, and 378 engine's brake thermal efficiency by 50%. Super Truck-I (Delgado and Lutsey 379 2014) program was successful in achieving its goals and the industrial partners even 380 exceeded their commitments (Diesel 2013; Stanton 2010; Gibble 2013). The 381 improvements made during the program not only involved powertrain components 382 but also advanced several vehicle components including aerodynamics, transmis-383 sions, chassis, air-conditioning, tires, and auxiliaries. As a result, many significant 384 efficiency improvement technologies were developed and are in the process of 385 commercialization, which will further help vehicle manufacturers around the world. 386 To further improve the heavy-duty segment, Super Truck-II (Gilroy 2016; Mulero 387 2016) was launched in 2016 and brings onboard teams from industry and national 388 labs to research, develop, and demonstrate greater improvement in vehicle freight 389 efficiency thereby cutting down significantly on CO₂ emissions. 390

EU has taken a less involved approach to improvising the efficiency of 391 heavy-duty vehicles as compared to the US. The EU plans to regulate CO₂ emis-392 sions (European Commission 2017) and the targets have been announced in 2018. 393 AEA-Ricardo (Rexeis and Kies 2011) and TIAX (Transportation TICoC 2011) 394 reports described extensive research effort by major heavy-duty manufacturers such 395 as Daimler (2017), Scania (2017) and Volvo for increasing diesel engine's effi-396 ciency. Major initiatives include improving the combustion system via higher 397 pressure fuel injection systems, reducing engine friction, waste-heat recovery 398 turbo-compounding, and other improvements in the engine such as friction 399 reduction in other parts of the powertrain, redesigning of accessories, etc. These 400

9	Layout: T1_Standard	Book ID: 472069_1_En		Book ISBN: 222-22-222-222-2

2 Combustion-Based Transportation in a Carbon-...

measures are taken continuously to reduce vehicle CO₂ emissions in addition to
 other developments such as aerodynamics, the increment of bio-component into the
 fuel blends and hybridization of drivetrains.

404 2.3.3 Recent Developments in Marine Sector

There are several proposed compliance options to meet the upcoming IMO regulations 405 and aspirations. As far as the availability of 0.5% m/m Low Sulphur Fuel Oil (LSFO) to 406 meet the IMO Sulphur cap is concerned, there have been conflicting reports on the 407 availability of such fuel. A study (Delft 2016) on the availability of compliant LSFO by 408 the IMO chartered CE-Delft reported that all refineries have the capability to supply 409 sufficient quantities of marine fuels with a Sulphur content of 0.50% m/m or less and with 410 a Sulphur content of 0.10% m/m or less to meet demand for these products, while also 411 meeting demand for nonmarine fuels. On the other hand, Ensys and Navigistics sup-412 plemental marine fuel availability study (Navigistics Ea 2016) presented to IMO sug-413 gests that the global refining industry will lack sufficient capacity to fully respond to the 414 IMO Sulphur cap resulting in the price increase of not only fuel oil but also distillates and 415 sweeter (low Sulphur) crudes. It is expected that the traditional fuels compliance option 416 will be a mix of distillates (MGO/MDO), LSFO, and their blends; based on the com-417 pliance option used, the price for IMO-compliant marine fuels would be significantly 418 more than HFO causing an increase in freight tariffs and will eventually result in some 419 degree of stress on world economy. LNG is proposed as an important alternative option 420 to HFO and LSFO in the marine sector. It offers several advantages; using a gas (LNG)-421 only engine can reduce the SO_x and soot emissions by almost 100% without further need 422 of after-treatment with manageable NO_x emissions. The CO₂ saving potential of LNG 423 compared to HFO is high (5-30%) but methane slip issues currently reduce the total CO₂ 424 savings (0-20%). Depending on the location, LNG is also price competitive to distillates 425 (MGO/MDO) compliance option with a discount of around \$5/MMBtu (Studies TOIfE 426 2018a). However, there is a severe infrastructure development barrier that the LNG 427 markets need to overcome for any meaningful marine market penetration and LNG share 428 in marine sector is expected to be around 5% by 2025 (WoodMackenzie 2018). 429

The other compliance option to meet IMO Sulphur cap is to use scrubber 430 technology for exhaust after-treatment of SO_{y} emissions. One of the challenges in 431 the uptake of the scrubber technology is the complexity associated with the ship-432 ping business. Typically, three to four parties are involved in the entire chain of the 433 shipping business, a shipbuilder who manufactures the ships based on the order by 434 shipowner, the shipowner either directly leases the ships-to-ship charterer or 435 through a middle company to ship charterers who operates the ship. The problem 436 with installing scrubbers is that the ship owners have no incentive to take their ships 437 out of service in the shipyards and also charterers do not see value in paying more 438 up front to the ship owners to make use of low priced HFO which in the long run is 439 a cheaper compliance option. Due to these reasons, scrubber technology is expected 440 to have a limited uptake of around 10-20% by 2020. 441

Alternative and renewable fuels	CO ₂ emissions reduction (%)	Current supply and uptake potential (% of total marine energy)
Advanced biofuels	25-100	15
LNG	0-20	1–5
Hydrogen	0-100	0
Ammonia	0-100	0
Methanol	25-100	0-1

Table 2.4 Estimated life cycle CO_2 emissions reduction and current supply and uptakeavailability of alternative and renewable fuels (adopted from ITF 2018)

Several alternative and renewable fuel options are receiving increased attention 442 in the marine sector to meet the upcoming SO_x, NO_x, and CO₂ emissions regula-443 tions and aspirations. These include advanced biofuels, LNG, Hydrogen, Ammonia, 444 and Methanol. These options intrinsically produce negligible (well below the 0.5% 445 Sulphur cap) SO_x emissions, manageable NO_x emissions that could be treated using 446 conventional selective catalytic reduction (SCR)-based exhaust after-treatment, and 447 based on the process used for production, can be fully CO₂ neutral. Table 2.4 448 shows some estimates on CO2 savings and current supply and uptake potentials of 449 these options for the marine sector. It can be seen from Table 2.4 that although the 450 potential CO₂ savings could be quite significant, depending on the synthesis process 451 of these fuels, the current supply and uptake potential of most of these options, 452 apart from LNG, is quite limited. It is expected that the marine sector will continue 453 to be dominated by oil-based residual and distillate fuels. 454

Furthermore, various technological and operational measures have been pro-455 posed to improve the overall energy efficiency of the marine sector (ITF 2018). The 456 traditional energy efficiency criteria for the new ships is the so-called Energy 457 Efficiency Design Index (EEDI), which measures the CO₂ emissions of the ships 458 and is expected to reduce the CO₂ footprint by 30% by 2030. Other proposed 459 technological measures that are expected to improve the energy efficiency of the 460 ships include using lighter materials to reduce the weight of the ship, slender design 461 for improved hydrodynamics, friction reduction using specialized hull coatings and 462 air lubrication, and incorporating ways to recover waste heat. Operational measures 463 for improving the energy efficiency of the shipping industry include reducing ship 464 speed, increasing ship size, improving the ship-port interface, and providing 465 onshore power at the port. 466

467 2.3.4 Recent Developments in Aviation Sector

As explained earlier, the aviation sector is set to rely greatly on the CORSIA mechanism for carbon-neutral growth from 2020. As such, it is expected that oil-based jet fuels will continue to power the aviation sector. The approved Sustainable Aviation Fuels (SAFs) under ASTM D7566, the standard for

Regulations	5	4	1	3
Evolution of technology	5	3	2	2

specifications for aviation turbine fuel containing synthesized hydrocarbons, 472 include Fischer-Tropsch hydro processed synthesized paraffinic kerosene 473 (FT-SPK), synthesized paraffinic kerosene produced from hydro processed esters 474 and fatty acids (HEFA-SPK), synthesized iso-paraffins produced from hydro pro-475 cessed fermented sugars (SIPS-HFS), synthesized kerosene with aromatics derived 476 by alkylation of light aromatics from non-petroleum sources (SPK/A), and alcohol 477 to jet synthetic paraffinic kerosene (ATJ-SPK). These SAFs are expected to be 478 blended in a certain ratio (10-50%) with typical aviation jet kerosene fuels; as such, 479 there are many questions and barriers that need to be overcome by SAFs to have 480 any meaningful market share; there are concerns on the environmental benefits of 481 these fuels (well to wings life cycle footprint), and on the cost and availability of 482 these SAFs. 483

Overall, it is the light-duty road transportation sector where the regulations are 484 stringent and to meet these regulations most of the innovation in engine/fuel 485 technology is witnessed. Heavy-duty road transportation sector has also seen a 486 surge in legislation for regulating emissions and pollutants and is closely following 487 light-duty segment's lead. The reason for relatively strict regulations for light- and 488 heavy-duty segment stems from the fact that these vehicles have higher visibility in 489 urban and rural spaces where they are often used for transporting people and goods. 490 Additionally, the rapid evolution of technology to meet the regulations has led to 491 tighter regulations in these segments. The regulations in Aviation or Marine sector 492 are still evolving, but several recent developments highlighted in this chapter 493 indicate that tighter legislation will soon be in place. A tabular comparison is 494 presented in Table 2.5 to further summarize the state of regulations and their 495 implementation in various mobility segments on the scale of 1–5 with 5 being 496 highest. 497

498

499

2.4 Technology Trends of Internal Combustion Engines Toward High Efficiency

For the light-duty (LD) passenger transport applications, spark-ignited (SI) engines are mainstream, except Europe, and there is a lot scope for improvements. The gaseous emissions such as hydrocarbon (HC), carbon monoxide (CO), and nitrogen

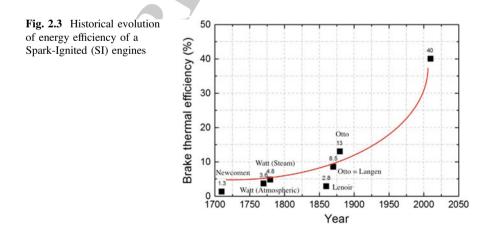

9	Layout: T1_Standard	Book ID: 472069_1_En		Book ISBN: 222-22-222-222-2
Ŋ	Chapter No.: 2	Date: 11-10-2018	Time: 2:23 pm	Page: 22/34

T. Javed et al.

oxide (NO_x) are treated by three-way catalytic converter with emissions levels 503 being already very low. Therefore, all research directions with SI engines are geared 504 toward the improvement of engine efficiency based on several strategies. The 505 commercial transport applications such as heavy-duty truck, and marine sector rely 506 on compression ignition (CI) engines. CI engine is more efficient than SI engines; 507 however, the emissions of NO_x and soot are higher, and diesel after-treatment is 508 quite expensive. The best possible way to mitigate these emissions would be 509 through in-cylinder phenomenon to achieve low-temperature combustion 510 (LTC) without compromising the efficiency. The other goals pertaining to CI engine 511 research are to maximize the engine efficiency by analyzing the thermodynamic 512 cycles and to develop a fuel-flexible hardware. The trends and recent developments 513 in this context are explained in the following sections. 514

515 2.4.1 High-Efficiency SI Engine Research

Ever since the advent of the combustion engine, the thermal efficiency of the ICE 516 has continuously improved. The evolution of efficiency over the past few centuries 517 is depicted in Fig. 2.3. The significant breakthrough came in 1876 from Nikolaus 518 August Otto, who pioneered the invention of an engine that is commonly referred to 519 as a gasoline engine. With the advancement in fuel supply system from the con-520 ventional carburetor to port fuel injection (PFI) system, the efficiency improved to 521 35%. Subsequently, the transition from the PFI system to Gasoline Direction 522 Injection (GDI) system is marked as one of the technological milestones towards 523 higher efficiency in SI engine development (Zhao et al. 1999). The direct injection 524 of fuel into the cylinder with the GDI system reduces the global equivalence ratio, 525 and the cooling effect also adds to improvement in efficiency. In the wake of 526 various engine development strategies, the current efficiency of the SI engine has 527 increased to 42%. Researchers are still in the race to achieve better thermal 528

6	Layout: T1_Standard	Book ID: 472069_1_En	Book ISBN: 222-22-222-2
Ŋ	Chapter No.: 2	Date: 11-10-2018 Time: 2:23 pm	Page: 23/34

2 Combustion-Based Transportation in a Carbon-...

efficiency and the key technology enablers are (1) Engine downsizing (2) Lean burn technology with dilution tolerance, and (3) Government-level initiatives such as the

531 Co-Optima Program.

532 2.4.1.1 Engine Downsizing

Increasing the compression ratio of the SI engine and diluted combustion are 533 important pathways to improve the efficiency of the engine. However, attaining a 534 maximum compression ratio is limited by engine knock and dilution decreases the 535 burnt rate of combustion. Engine downsizing is an effective approach to improve 536 the efficiency that directly relates to the reduction of carbon footprint (Turner et al. 537 2014). Despite the smaller displacement volume of the engine, the power output is 538 higher through boosting that helps to induct more air to burn the fuel. Reducing the 539 pumping, frictional and heat losses reduces the fuel consumption with the reduced 540 engine out emissions (Avola et al. 2015). The pressure/temperature history of these 541 modern engines are far away from the RON/MON conditions in that the octane 542 rating scale is no longer agreeable. These engines depend on a factor "k", which is a 543 constant in the octane index formulation (OI = RON – k * S). The factor "k" is 544 negative for highly boosted downsized engines when knock limited and requires 545 fuels with higher octane sensitivity (Avola et al. 2015). Variable Geometry Turbine 546 (VGT) is a technological advancement in the development of turbocharged engines 547 that allows for a fast transient response to synergize appropriately with the engine 548 (Tang 2016). Currently, Mazda, Ford and Chevrolet, BMW, Mercedes-Benz, and 549 Volkswagen Auto Group adopt downsized GDI engine with turbocharger tech-550 nology. The maximum efficiency of the reported commercial engine is 35% and 551 efforts are being taken to further increase the efficiency. This advanced powertrain 552 coupled with hybrid technology is beneficial and Toyota Prius plug-in hybrid 553 electric vehicle showed a brake efficiency of 42%. Dilution through Exhaust Gas 554 Recirculation (EGR) is an effective approach in a turbocharged GDI engine. Diluted 555 combustion relates to stoichiometric operation in boosted downsized gasoline 556 engines and offers greater potential to reduce fuel consumption (Wei et al. 2012). 557 Cooled EGR reduces the engine knock, minimizes pumping losses and avoids the 558 enrichment zones to improve fuel economy. However, the development of flame 559 kernel under heavily diluted condition is difficult and high spark discharge system is 560 recommended. Honda R&D recently demonstrated 45% efficiency using 35% EGR 561 at an engine speed of 2000 rpm with an optimized combustion chamber design 562 (Ikeya et al. 2015). In order to overcome the dilution tolerance and support 563 auto-ignition; higher spark energy of 450 mJ is used. A 3% increase in efficiency 564 when compared to the existing commercial vehicle is a promising improvement. 565 When coupled with hybrid concept, the efficiency of this engine is expected to be 566 the highest that has been conceived thus far. 567

568

T. Javed et al.

8 2.4.1.2 Lean Burn Technology

Lean combustion in SI engines improves the fuel economy and reduces the global 569 CO₂ emissions (Tully 2002; Ayala and Heywood 2007). Moving from stoichio-570 metric to lean mixture increases the specific heat ratio and reduces the pumping 571 losses, which increases the thermal efficiency. However, the disadvantage of this 572 technology is the incompatibility of the catalytic converter at lean conditions. 573 Catalytic converter is effective only at stoichiometric ($\phi = 1$) condition and, 574 therefore, the use of lean technology leads to increased HC and CO emissions. The 575 main problem with the lean combustion technology is the inadequacy of the igni-576 tion energy supplied from the spark plug. As the mixture is lean, the ignition energy 577 is increased to improve the combustion stability and tolerate the dilution level (Shah 578 et al. 2012; Toulson et al. 2010). Thus, development and characterization of the 579 ignition system for lean-burn SI engines are crucial. 580

In a measure to adopt lean combustion technology in modern gasoline engines, 581 Turbulent Jet Ignition (TJI) thorough pre-chamber combustion system was pro-582 posed (Alvarez et al. 2017). While the spark energy is not sufficient to burn the lean 583 mixture in a gasoline engine, Turbulent Jet Ignition (TJI) is favorable to support 584 lean combustion. The pre-chamber system is incorporated in place of a spark plug 585 in the cylinder head. Initially, the TJI concept was applied for operation of natural 586 gas in an SI engine to improve the efficiency (Attard et al. 2012a). Currently, 587 gasoline only system substitutes the use of natural gas with improved durability 588 (Attard et al. 2012b). According to the pre-chamber concept that functions with 589 gasoline alone, a small quantity of liquid fuel is injected in the pre-chamber. In the 590 main combustion chamber, fuel is directly injected early in the cycle so that a lean 591 mixture is formed. Given the volume of pre-chamber is only 3% of the main 592 combustion chamber, a rich mixture is burnt in the pre-chamber to create a stratified 593 charge. The more active radicals of the burnt mixture in the pre-chamber pervade as 594 turbulent jets into the main combustion chamber and create multiple ignition sites. 595 This turbulent jet has more active energy compared to the spark energy and 596 increases the mass burnt rate. The increased flame propagation extends the knock 597 limit that helps to improve the efficiency. MAHLE powertrain showed an ultra-lean 598 homogeneous combustion ($\lambda \sim 1.6$) with an efficiency of 42.8% based on a new 599 design of pre-chamber system in a gasoline engine (Bunce and Blaxill 2016). Since 600 knock is limited, the compression ratio of the engine can be increased (hardware 601 upgrade) to further increase the efficiency up to 45%. Based on pre-chamber jet 602 ignition system, HONDA (i-CVCC) demonstrated an efficiency of 47.2%. These 603 technologies would be commercialized in the near future so that the benchmark to 604 compete with would be a higher efficiency of around 48-50%. 605

606 2.4.1.3 Government Level Initiatives (Co-optima Program)

The Co-Optima Program aims to introduce clean, efficient, and high-performance engine by establishing synergy between fuel and engine technologies (U.S. DOE

£	Layout: T1_Standard Book ID: 472069_1_En		En	Book ISBN: 222-22-222-222-2
5	Chapter No.: 2	Date: 11-10-2018	Time: 2:23 pm	Page: 25/34

2 Combustion-Based Transportation in a Carbon-...

2016). The Co-Optima approach helps to identify new blend-stock that can be 609 blended with gasoline to improve the performance of the vehicle and reduce the 610 emissions. The selection of blend-stock from domestic resources delineates to 611 cellulosic biomass, renewable, nonfood, and surplus resources. The blend-stock is 612 evaluated based on the fuel properties and design parameters that maximize the 613 efficiency of the engine through mitigation of knock. Research Octane Number 614 (RON), octane sensitivity (S = RON - MON), and heat of vaporization are the 615 important properties that improve knock resistance of modern SI engines. For 616 achieving these favorable properties, the chemical families identified are alcohols. 617 ketones, furans, alkenes, and aromatics. The blend-stock produced from any of 618 these families when blended with gasoline improves efficiency. Before blending, 619 the compatibility of these blend-stocks on engine infrastructure is screened. 620 Furthermore, system-level analysis of these blend-stocks with respect to economic, 621 technological, market, and environmental factors is imperative. The gasoline 622 blended with the blend-stock is operated in a boosted SI engine to result in a highly 623 efficient co-optimized fuel/engine system. The Co-Optima researchers demonstrated 624 a direct correlation between knock performance and Octane Index (OI), which is a 625 crucial derived property (OI = RON - k * S). While Low-Speed Pre-Ignition 626 (LSPI) limits the engine efficiency, measures to identify and prevent pre-ignition 627 occurrence for various gasoline blends under boosted conditions are developed. 628 Computational analysis based on numerical algorithms and validated engine models 629 provide insights into the development of the engine, which cannot be operated in a 630 laboratory scale due to practical limitations. The co-optimized engine operated 631 under multi-mode combustion concept is the next step to further increase the effi-632 ciency. Overall, fuel properties and advanced combustion concepts help to improve 633 engine efficiency, and programs like Co-Optima could facilitate the identification of 634 optimum fuel-engine combination. 635

636 2.4.2 High-Efficiency CI Engine Research

Diffusion-controlled spray combustion leads to the formation of increased NO_x and 637 soot emissions in a CI engine. Today's commercial medium and heavy-duty fleets 638 adopt the Mixing-Controlled Compression Ignition (MCCI) concept for gaining 639 higher efficiency but require effective emission control technologies. The diesel 640 after-treatment utilizes Selective Catalytic Reduction (SCR) and particulate filter to 641 reduce the NO_x and particulate matter emissions, whereas HC and CO emissions are 642 decreased by Diesel Oxidation Catalyst (DOC) (Johnson 2010). These 643 after-treatment devices are much more complex and expensive when compared to 644 the three-way catalytic converter in SI engines. High-pressure Common Rail fuel 645 Direct Injection (CRDI) system is a pioneering technology to improve the fuel 646 atomization and air/fuel mixing. However, the advancement from mechanical 647 injection to CRDI system could not mitigate the deleterious emissions of NO_x and 648 PM. Measures to overcome this problem has been up-taken over several decades 649

(I)	Layout: T1_Standard	Book ID: 472069_1_En		Book ISBN: 222-22-222-222-2
	Chapter No.: 2	Date: 11-10-2018	Time: 2:23 pm	Page: 26/34

T. Javed et al.

and paved the way to the development of new combustion concepts. Instead of 650 after-treatment technique, advanced combustion concepts such as Homogenized 651 Charge Compression Ignition (HCCI) and Partially Premixed Combustion 652 (PPC) are proposed for simultaneous reduction of NO_x and soot emissions (Zheng 653 2009; Noehre et al. 2006). Furthermore, these combustion strategies also improve 654 the efficiency due to low-temperature combustion (minimized heat loss), which 655 mitigates the CO₂ emission. Besides new combustion concepts, the thermodynamic 656 cycle analysis to realize higher efficiency has been investigated and researched. The 657 eight-stroke engine is the latest technology that improves the thermodynamic 658 process to reduce the heat losses and allows for efficiency improvements. These 659 renewed combustion concepts that aim to achieve 60% efficiency are current 660 research initiatives pertaining to CI engine technology. 661

662 2.4.2.1 High-Efficiency Combustion Concepts

Few in-cylinder combustion strategies proposed to mitigate NO_{y} and soot emission 663 without compromising engine efficiency including HCCI, PPC, and Reactivity-664 Controlled Compression Ignition (RCCI) (Sarangi 2012). These Low-Temperature 665 Combustion (LTC) concepts reduce the local flame temperature and equivalence 666 ratio in such a way that NO_x and soot formation are reduced simultaneously. When 667 the Start of Injection (SOI) is advanced from late to early fuel injection timings, 668 combustion drifts from CI toward HCCI condition (Vallinayagam et al. 2017). 669 In HCCI mode, fuel and air are completely premixed during the significant delay 670 period and combustion is controlled by mixture chemical kinetics. Given that the 671 controllability of combustion is a problem at high load with HCCI due to rapid 672 pressure rise rate; studies on PPC emerged that effectively controls combustion due 673 to increased combustion stratification (Najafabadi 2017). While combustion phas-674 ing is sensitive to SOI in CI combustion, it is dependent on intake air temperature 675 for HCCI combustion. PPC is intermediate between HCCI and CI combustion in 676 that the fuel injection is crucial for controlling the combustion phasing. In 2001, 677 Nissan Motor Company investigated diesel PPC through modulated kinetics 678 combustion concept (Kimura et al. 2001). Based on EGR, the required ignition 679 delay was created at various loading conditions. Due to low temperature and pre-680 mixed combustion, a simultaneous reduction in NO_x and soot emission was 681 achieved. The high load diesel operation demanded 70% EGR, which deteriorated 682 the combustion process. Given that diesel PPC was not advantageous at all the 683 operating ranges, gasoline PPC was introduced in 2006 (Kalghatgi et al. 2006). 684 When fuels with resistance to auto-ignition are used in CI engines, they create an 685 adequate delay period for premixing; this decreases the in-cylinder temperature to 686 suppress NO_x formation, while local fuel to air equivalence ratio is decreased to 687 reduce soot emission. Gasoline PPC is also described as Gasoline Compression 688 Ignition (GCI), which has grabbed more attention in the past decade and most of the 689 engine manufacturers are in the endeavor to commercialize the first GCI engine 690 (Perkins 2018). 691

(I)	Layout: T1_Standard	Book ID: 472069_1_En	Book ISBN: 222-22-222-222-2

2 Combustion-Based Transportation in a Carbon-...

Ignition assistance is required to support the auto-ignition and maintain com-692 bustion stability when using high RON gasoline fuel in a Compression Ignition 693 (CI) engine. However, high RON fuels prove difficult to auto-ignite at low load 694 condition, as the available boost is limited (Manente et al. 2009). In the current 695 scenario, low-load GCI is a big challenge and efforts are being made to improve the 696 combustion stability. Selection of low RON gasoline could avert this problem and 697 RON 70 gasoline is an ideal candidate for GCI investigation (Solaka et al. 2012). 698 Naphtha (a low octane gasoline fuel with RON \sim 60–70) has been tested as a 699 suitable fuel for GCI engines (Alabbad et al. 2018; Leermakers et al. 2013) due to 700 its suitable fuel properties such as its optimal reactivity to ignite under compression, 701 low well-to-tank carbon footprint due to reduced refinery processing and higher 702 H to C ratio (due to paraffinic composition) ascertaining lower tank-to-wheel carbon 703 emissions. Furthermore, based on its boiling point (BP), naphtha can be categorized 704 as light (BP = 75 °C) or heavy (BP = 175 °C). Since it is a less-processed fuel, less 705 refining energy is required thereby reducing production costs; it is also less 706 intensive in terms of reduced well-to-tank CO₂ emission. The vehicular demon-707 stration of naphtha in a PPC engine demonstrated improved fuel economy and 708 better combustion stability at low load condition (Chang et al. 2013). Thus, 709 low-load operation of GCI is possible without any auto-ignition problems using low 710 RON gasoline or naphtha. However, the low RON gasoline fuels are not com-711 mercially available and adaption of these fuels could be a choice in the future. At 712 present, high RON gasoline is being used commercially and strategies to overcome 713 auto-ignition problems and enable low load and idle operation are essential. In this 714 respect, Delphi is involved in the development of Gasoline Direct injection 715 Compression Ignition (GDCI) engine using US market gasoline (Sellnau et al. 716 2014, 2016). The fuel injection strategy was implemented in such a way to achieve 717 PPC at very low fuel injection pressure, typical of GDI engines. Delphi electrical 718 cam phaser's actuated the exhaust valve train to enable secondary valve lift, 719 recuperating heat from hot exhaust gases to support auto-ignition at low loads. 720 Retaining the residuals helps to reduce the oxygen flow rate and local flame tem-721 perature with increased heat capacity. The longer ignition delay also influences the 722 local fuel to air equivalence ratio. As such, both NO_x and soot emissions are 723 simultaneously reduced, indicating low-temperature combustion. Measures to 724 control the combustion by providing spark assistance provided a better solution 725 (Manofsky et al. 2011). Spark-assisted GCI is the evolving technology toward the 726 extension of low load limit until now (2018). A recent innovative combustion 727 concept called Spark-Assisted Compression Ignition (SACI) of gasoline was 728 introduced by MAZDA (2018). With Mazda's Skyactive-X is ready for launch on 729 2019, it is touted as the world's first commercial gasoline engine running on 730 compression ignition mode. 731

The pictorial layout in Fig. 2.4 elucidates the different high-efficiency combustion concepts that have been identified thus far.

Fig. 2.4 Advanced high-efficiency combustion concepts for ICE

2.4.3 Eight-Stroke Engine Concept (High-Pressure Combustion)

Eight-stroke concept is a staged engine concept and is an alternative step to achieve 736 up to 60% engine efficiency (Lam et al. 2015). Staged or complex engines have 737 been around for over a century. Most powertrains are staged engines with a rotary 738 compressor and expander before and after the piston machine. The reason to assess 739 replacing these rotary units with piston machines is the greater efficiency of piston 740 machines at volumes that are typical of light- and heavy-duty engines. The chal-741 lenge to attain maximal efficiency from this architecture requires a thorough 742 understanding of inherent loss mechanisms. The 1D modeling of such complex 743 devices provides us a design tool to evaluate the performance of such a device with 744 various design features such as staging ratios, insulation, modifications to air path, 745 and combustion concepts (Shankar et al. 2017, 2018). The development of any 746 high-efficiency system must also consider the boundary conditions for an effective 747 after-treatment system, which is also evaluated using 1D gas exchange models. The 748 concept is a bit down the road from being fully realized as only a demonstrably 749 superior efficiency compared to present architectures could convince manufacturers 750 to adopt this technology. 751

2.5 Disruptions in Transportation Sector and Policy Implications

Transportation sector is going through a major disruption phase and personal
 mobility is on the cusp of change from what we have known for the past 50 years or
 so, and such disruptions are most evident in the LDV road transportation sector.
 Electrification and hybridization are important disruption agents (Studies TOIFE
 2018b). In recent years, several new technologies have featured in the otherwise

(I)	Layout: T1_Standard	Book ID: 472069_1_En	Book ISBN: 222-22-222-2
	Chapter No.: 2	Date: 11-10-2018 Time: 2:23 pm	Page: 29/34

2 Combustion-Based Transportation in a Carbon-...

ICE-dominated LDV road transport sector. These include HEVs, PHEVs, BEVs, 759 and FCVs. Of these technologies, HEVs and PHEVs, depending on the mode of 760 operation (e.g., charge sustaining versus charge depleting modes in PHEV), still 761 rely heavily on ICE as primary energy source in the vehicle, and only the BEVs. 762 typically of limited driving range, are powered by fully electrified powertrains; 763 nonetheless, it has to be acknowledged that pure ICE vehicle models, without any 764 hybridization or electrification, may well be phased out from the LDV sector in the 765 next 15-20 years time frame. In much of the popular media, such disruptions, in 766 one form or the other, are readily linked to an eventual demise of oil-based 767 ICE-powered vehicles. Such a hype should be evaluated cautiously as the tech-768 nologies go through many hype and disappointment cycles before they make a 769 major impact in the market or die down (Melton et al. 2016). Kalghatgi in his recent 770 work tried to answer some of the hype associated with this notion in his paper titled 771 "Is it really the end of internal combustion engines and petroleum in transport?" 772 (Kalghatgi 2018). He argues that, for LDVs, available battery capacity will have to 773 increase by several hundred-fold, perhaps by several thousand-fold, for complete 774 electrification. This will have serious economic, social, environmental, and political 775 impacts and, as such, is highly unlikely in near future. In addition, the requirements 776 for complete electrification of HDVs are even more stringent (Kalghatgi 2018; 777 Sripad and Viswanathan 2017), and are so extreme for marine and aviation, that 778 proposing such electrified solutions for them, even in the presence of current media 779 hype, should be backed up by thorough, unbiased and scientific analyses of which 780 nothing could be found in literature. Hence, unless renewable electricity becomes 781 abundantly available and price competitive, the massive infrastructure requirements 782 for electrification are dealt with, and the battery capacities and costs dramatically 783 improve to meet the transportation needs, transportation sector is expected to be 784 powered by oil-based solutions, in one form or another, particularly for HDVs, 785 marine, and aviation, for the foreseeable future. Hybridization of ICE vehicles is the 786 most probable way forward for improving the efficiency and environmental foot-787 print of ICE-only vehicles, and the transition of transportation, even for LDVs, to 788 complete electrification will be evolutionary and not disruptive spanning several 789 decades. 790

The other disruptive agents in the transportation sector, again primarily in the 791 LDV sector, are the emergence of shared mobility and autonomous vehicles 792 (Studies TOIfE 2018b). The Ubers, the Lyfts, the Careems, etc., model of trans-793 portation as a service has certainly received widespread acceptance since such a 794 model allows the consumers to have a ride ready whenever and wherever they want 795 without worrying too much about the problems (parking, refueling, service, 796 maintenance, insurance, etc.) associated with the transportation ownership model. 797 The advent of shared mobility model and the autonomous vehicles also combine 798 well with each other and it is expected that in future, especially in big metropolises, 799 these two disruptive agents will steadily overtake the transportation ownership 800 model. The cost of such rides per kilometer are expected to come down; and 801 although the transportation as a service model and autonomous vehicles will 802 improve the traffic congestion and problem related to ever-increasing cars, the total 803

(R)	Layout: T1_Standard	Book ID: 472069_1_En		Book ISBN: 222-22-222-222-2
	Chapter No.: 2	Date: 11-10-2018	Time: 2:23 pm	Page: 30/34

T. Javed et al.

number of kilometers are expected to be increased because of the ease of use 804 offered by such models (Studies TOIfE 2018b). The profit margin and continuous 805 vehicle availability are expected to be among major considerations of the vehicle/ 806 fleet operators under transportation as a service model, again, complete electrifi-807 cation of the LDV fleet in such a model could only be realized if the electric cars 808 become price competitive and the charging times and the mileage of BEVs sig-809 nificantly improve. Fleet operators will also closely monitor all of these parameters 810 for the scenarios where the government provided subsidies for electric vehicles and 811 battery charging dry out. 812

In addition to the disruptions discussed above, some countries have announced 813 their aspirations to ban ICE-only vehicles. Such aspirations are meant to curb the 814 pollutants related to local air quality, the NO_x, SO_x, CO, HCs and soot emissions, 815 and the climate change. The governments of UK, France, China, India, Germany, 816 along with city administrators of major metropolises including Paris, Barcelona, 817 Madrid, have expressed aspirations to ban ICE only vehicles in 2030-2040 time-818 frame. Most of these aspirations are announced in the popular media without formal 819 government-level proposals or regulations drafted thus far. Implicit in these news is 820 the fact that most of these countries, although aspire to ban ICE-only vehicle, will 821 still continue to use combustion engine hybridized in one form or another as a 822 primary energy source for the vehicles. It is beyond question that transportation 823 must do more to improve its environmental footprint. However, it is equally 824 important that the governments and regulators, instead of picking the winners, take 825 a balanced and informed approach while formulating policies and regulations for 826 the transportation sector. Life Cycle Analysis (LCA)-based policies and 827 decision-making (Abdul-Manan 2018) should be adopted to arrive at scientifically 828 backed policies and practical solutions to improve the environmental impact of the 829 transportation sector. All the technological options should be properly evaluated 830 utilizing LCA-based methodologies to arrive at a sustainable transportation model 831 for the future. Policy makers and regulators must avoid simple burden shifting as 832 such short-sighted approaches may alleviate the pollution concerns in the cities but 833 may not overcome the climate change concerns globally. 834

835 2.6 Conclusions

The mobility of man and goods accounts for around a quarter of greenhouse gas 836 emissions globally and, therefore, naturally attracts the most stringent regulations 837 for emissions and fuel efficiency. Here, current and prospective regulatory frame-838 work for road, marine, and aviation transport sectors, aimed at curbing the CO₂ 839 emissions from the transportation is presented. It is shown that the fuel economy 840 and CO₂ emission targets are becoming stricter across the various transportation 841 sectors. For light-duty sector, such regulations are even more stringent and the 842 recent introduction of zero-emission mandates is forcing the OEMs to invest more 843 in hybridization and electrification. The available compliance options for various 844

2 Combustion-Based Transportation in a Carbon-...

transport sectors are also discussed. Holistically speaking, the fossil fuel powered 845 combustion engines/turbines are expected to continue powering the transport sector 846 for decades to come. The passenger transport sector is expected to have a slow 847 transition, spanning several decades, towards electrification. Several advanced 848 engine technologies, with the potential to improve fuel economy and CO₂ emis-849 sions, including highly boosted and downsized SI engine concepts, pre-chamber SI 850 engine concept. 8-stroke and GCI/PPC CI concepts are briefly discussed. Various 851 disruption agents are presented, especially in the light-duty sector, and it is expected 852 that the personal mobility models may change in the near future. Finally, it is 853 argued that a LCA-based policy must be adopted for proposing any future regu-854 lations for the transport sector. 855

Author Query Form

Book ID : **472069_1_En** Chapter No : **2**

Please ensure you fill out your response to the queries raised below and return this form along with your corrections.

Dear Author,

During the process of typesetting your chapter, the following queries have arisen. Please check your typeset proof carefully against the queries listed below and mark the necessary changes either directly on the proof/online grid or in the 'Author's response' area provided below

Query Refs.	Details Required	Author's Response
AQ1	Please check and confirm if the author names and initials are correct.	
AQ2	Please approve the edit made in the chapter title.	
AQ3	Please provide complete detail for references 'MARPOL Annex VI (2010), Daimler (2017), Scania (2017)'.
