Common Zeros of Two Bessel Functions Part II. Approximations and Tables

By T. C. Benton*

Abstract. In [1] it was shown that two Bessel functions $J_\nu(x)$, $J_\mu(x)$ could have two zeros which were common to both functions, and a computer program was made which takes approximate values of ν, μ and $j_{\nu,k} = j_{\mu,h}$ and $j_{\nu,k+n} = j_{\mu,h+m}$ and from them computes the exact values. Here it will be shown how to find the necessary approximate values to initiate the computation. A table of the smaller ratios $m:n$ with the orders of the functions less than one hundred is given.

1. Introduction. In our paper [1] on common zeros of two Bessel functions we developed a computer program which takes rough approximations to the orders μ, ν ($\nu > \mu$) of the Bessel functions of the first kind $J_\nu(x)$ and $J_\mu(x)$ and to the positions of the two common zeros and derives the exact values. In this paper methods of obtaining the initial approximations will be discussed and a table of values given.

2. Notation. It is understood that the orders μ, ν are real numbers $\geqslant 0$. The zeros of $J_\nu(x)$ will be denoted by $j_{\nu,s}$, and $j_{\nu,1}$ is the first positive zero with $j_{\nu,s+1} > j_{\nu,s}$, s is referred to as the rank of the zero. If the functions $J_\nu(x)$, $J_\mu(x)$ have a pair of common zeros $j_{\nu,k} = j_{\mu,h}$ and $j_{\nu,k+n} = j_{\mu,h+m}$, it will be convenient to speak of n intervals of $J_\nu(x)$ covering m intervals of $J_\mu(x)$, it being understood that the intervals are the segments between two successive zeros and the numbers h, k, m, n are all integers.

3. Properties of the Zeros. The sequence of zeros of $J_\nu(x)$, call it $[j_{\nu,s}]$, is an increasing sequence. If $0 < \nu < \frac{1}{2}$, the intervals $j_{\nu,s+1} - j_{\nu,s}$ are less than π and approach π as $s \to \infty$, but for $\nu > \frac{1}{2}$ they are greater than π and decrease toward π as $s \to \infty$; for $\nu = \frac{1}{2}$ they are all exactly π in length. If s is fixed and $j_{\nu,s}$ is considered as a function of the order ν, $j_{\nu,s}$ is a continuous increasing function of ν with

$$(1) \qquad \frac{\partial j_{\nu,s}}{\partial \nu} = 2 j_{\nu,s} \int_0^\infty K_0(2 j_{\nu,s} \sinh t) e^{-2\nu t}\, dt.$$

Proofs of these facts are contained in Watson's treatise [2], particularly in Chapter 15. Some other properties are contained in the following theorems.

THEOREM 1. *If s, t are fixed integers, $t > s$, and $j_{\nu,s}$, $j_{\nu,t}$ are zeros of $J_\nu(x)$ where ν is real and $\geqslant 0$, then $j_{\nu,t} - j_{\nu,s}$ is an increasing continuous function of ν.*

Proof. $\partial j_{\nu,s}/\partial\nu$ is given by (1) and

$$\frac{\partial j_{\nu,t}}{\partial\nu} = 2j_{\nu,t}\int_0^\infty K_0(2j_{\nu,t}\sinh\phi)e^{-2\nu\phi}\,d\phi. \tag{2}$$

Now $j_{\nu,s}$ and $j_{\nu,t}$, are not functions of the variable of integration ϕ, so if $j_{\nu,t}\sinh\phi = j_{\nu,s}\sinh\theta$ and $j_{\nu,t}\cosh\phi\,d\phi = j_{\nu,s}\cosh\theta\,d\theta$, (2) becomes

$$\frac{\partial j_{\nu,t}}{\partial\nu} = 2j_{\nu,t}\int_0^\infty K_0(2j_{\nu,s}\sinh\theta)e^{-2\nu\operatorname{arc\,sinh}((j_{\nu,s}/j_{\nu,t})\sinh\theta)}$$

$$\cdot\frac{j_{\nu,s}}{j_{\nu,t}}\left[1+\left(\frac{j_{\nu,s}}{j_{\nu,t}}\sinh\theta\right)^2\right]^{-1/2}\cosh\theta\,d\theta.$$

Since $j_{\nu,s}/j_{\nu,t} < 1$,

$$2\nu\operatorname{arc\,sinh}\left(\frac{j_{\nu,s}}{j_{\nu,t}}\sinh\theta\right) < 2\nu\operatorname{arc\,sinh}(\sinh\theta) = 2\nu\theta,$$

whence

$$e^{-2\nu\operatorname{arc\,sinh}((j_{\nu,s}/j_{\nu,t})\sinh\theta)} > e^{-2\nu\theta},$$

$$\left[1+\left(\frac{j_{\nu,s}}{j_{\nu,t}}\sinh\theta\right)^2\right]^{1/2} < [1+\sinh^2\theta]^{1/2} = \cosh\theta.$$

So it follows that

$$\frac{\partial j_{\nu,t}}{\partial\nu} > 2j_{\nu,s}\int_0^\infty K_0(2j_{\nu,s}\sinh\theta)e^{-2\nu\theta}\,d\theta = \frac{\partial j_{\nu,s}}{\partial\nu},$$

and so $\partial(j_{\nu,t}-j_{\nu,s})/\partial\nu > 0$ for all s and t with $t > s$. Q.E.D.

THEOREM 2. *If $J_\nu(x)$ and $J_\mu(x)$ have two common positive zeros with n intervals of $J_\nu(x)$ covering m intervals of $J_\mu(x)$ and $\nu > \mu$ and $\nu > \frac{1}{2}$, then $m > n$.*

Proof. Let the common zeros be $j_{\nu,k} = j_{\mu,h}$ and $j_{\nu,k+n} = j_{\mu,h+m}$. By Theorem 1, $j_{\mu,h+m} - j_{\mu,h}$ is an increasing function of μ. So if μ is increased to ν, $j_{\nu,h+m} - j_{\nu,h} > j_{\mu,h+m} - j_{\mu,h} = j_{\nu,k+n} - j_{\nu,k}$. Since $\nu > \mu$, $j_{\nu,k} > j_{\mu,k}$, but $j_{\mu,h} = j_{\nu,k} > j_{\mu,k}$ therefore $h > k$. Now if k is increased to h, $j_{\nu,h+n} - j_{\nu,h} < j_{\nu,k+n} - j_{n,k}$ if $\nu > \frac{1}{2}$ (Watson [2, bottom of p. 515]). It follows that $j_{\nu,h+m} - j_{\nu,h} > j_{\nu,h+n} - j_{\nu,h}$ and, since m, n are integers, $m > n$.

If one makes a diagram plotting ν as abscissa and $j_{\nu,s}$ as ordinate, keeping s fixed, a family of curves C_s ($s = 1, 2, 3, \ldots$) is obtained. As $\nu \to \infty$ the slopes of these curves approach different values. The slopes of the chords connecting $j_{10{,}000,s}$ and $j_{10{,}001,s}$ can be easily computed and for $s = 1$, $m = 1.00133$; $s = 4$, $m = 1.00385$; $s = 50$, $m = 1.02125$. This is an obvious consequence of Theorem 1, for in order that the differences of the ordinates of $j_{\nu,t}$ and $j_{\nu,s}$ should increase the curves must diverge as ν increases. If the value of ν is fixed and s increases, quite a different situation occurs. From Watson [2, p. 508, 15.6 (2)]:

$$\frac{\partial j_{\nu,s}}{\partial\nu} = \frac{2\nu}{j_{\nu,s}J_{\nu+1}^2(j_{\nu,s})}\int_0^{j_{\nu,s}} J_\nu^2(t)\frac{dt}{t}.$$

As $s \to \infty$, $j_{\nu,s} \to \infty$, $\int_0^\infty J_\nu^2(t)dt/t = 1/2\nu$ (Watson [2, p. 405]). Now if s is large, $j_{\nu,s}$

can be made larger than ν^2, so that the first term of the asymptotic series gives the good approximation

$$\theta = 2^{1/2}\pi^{-1/2}j_{\nu,s}^{-1/2}\cos\left(j_{\nu,s} - \frac{\nu\pi}{2} - \frac{\pi}{4}\right).$$

Thus $j_{\nu,s} = \pi/2 + k\pi + \nu\pi/2 + \pi/4$, where k is a large integer. So $J_{\nu+1}(j_{\nu,s}) = 2^{1/2}\pi^{-1/2}j_{\nu,s}^{-1/2}\cos k\pi$, and $j_{\nu,s}J_{\nu+1}^2(j_{\nu,s}) \to 2/\pi$ as $j_{\nu,s} \to \infty$. Then $\partial j_{\nu,s}/\partial\nu \to \pi/2$, and this is independent of the value of ν. This diagram is of interest because finding a pair of Bessel functions with two zeros in common is equivalent to finding a rectangle with sides parallel to the axes having all four of its vertices lying on the curves C_s. The diagram suggested the proof of Theorem 2.

4. Note on the Computation of Zeros of Bessel Functions. The Royal Society Tables 7, *Bessel Functions* [3] gives a table of the zeros $j_{\nu,s}$ of $J_\nu(x)$, $0 \leqslant \nu \leqslant 20.5$ (0.5), $1 \leqslant s \leqslant 50$ (1) together with the formulae for their calculation. Olver's uniform asymptotic series [3, p. XIX and Section 8, p. XXXVI] is very powerful for the calculation of zeros when $\nu > 20$ or $s > 50$. Using a TI59 calculator, a program was constructed to avoid the complicated use of Everett's interpolation formulae suggested in [3]. This was replaced by Newton's method for solving the equation $\sqrt{z^2 - 1} - \arccos 1/z - c = 0$. The coefficient p_1 was computed so that, in $j_{\nu,s} = \nu z + p_1/\nu - p_2/\nu^3 + \cdots$, the first two terms were sufficient in most cases to give at least five places of decimals, which is enough for the needed approximations.

5. The Difference Function $D(\nu)$. Consider the expression $(j_{\nu,k+n} - j_{\nu,k}) - (j_{\mu,h+m} - j_{\mu,h})$ with $j_{\nu,k} = j_{\mu,h}$, where k, h, n and m are fixed integers. Since k and h are fixed, the value of μ will be a function of ν and for a given ν only one value of μ exists so that $j_{\nu,k} = j_{\mu,h}$. If there were two different values, say μ_1, $\mu_2 > \mu_1$ such that $j_{\mu_1,h} = j_{\mu_2,h}$, this would contradict the fact that $j_{\mu,h}$ is an increasing function of μ. This makes the given expression (with the extra equality) a function of ν alone. Call it $D(\nu)$. Since by Theorem 1 each parenthesis is a continuous increasing function of its order (ν or μ) and since the difference of two continuous functions is continuous, it follows that $D(\nu)$ is a continuous function of ν. By a well-known property of continuous functions, if values ν_1 and ν_2 exist so that $D(\nu_1) < 0$ and $D(\nu_2) > 0$, there must be a value $\bar{\nu}$ such that $\bar{\nu}$ is between ν_1 and ν_2 and $D(\bar{\nu}) = 0$. Now there will be a value $\bar{\mu}$ such that $j_{\bar{\nu},k} = j_{\bar{\mu},h}$, and because $D(\bar{\nu}) = 0$, it will be true that $j_{\bar{\nu},k+n} = j_{\bar{\mu},h+m}$ and the two Bessel Functions $J_\nu(x)$ and $J_\mu(x)$ will have two zeros in common.

6. Some Approximations. (a) Consider the case $m = 2$, $n = 1$, $k = 1$ so that $[j_{\nu,2}, j_{\nu,1}]$ must cover $[j_{\nu,h+2}, j_{\nu,h}]$. Now two intervals for μ small will have $j_{\nu,h+2} - j_{\nu,h}$ approximately equal to 2π. From formulae developed by Olver [3, p. XVIII]

$$j_{\nu,2} - j_{\nu,1} = 1.388505\nu^{1/3} + 2.125093\nu^{-1/3} - 0.79333\nu^{-1} - 0.75291\nu^{-5/3} + \cdots.$$

If three terms are kept this equation becomes

$$1.389x^4 - 6.283x^3 + 2.125x^2 - 0.079 = 0, \qquad x = \nu^{1/3}.$$

This has a root $x = 4.156$, and so $\nu = 71.78$.

Suppose that $\nu = 72$ is used as an approximation, $j_{72,1} = 79.96646$. From tables [3] $J_0(x)$ has $j_{0,25} = 77.75603$ as its largest zero not greater than $j_{72,1}$ and $j_{1,25} = 79.32049 < j_{72,1} = 79.966464 < j_{1.5,25} = 80.09813$. By calculating $j_{\mu,25}$ with different values of

μ it was found that $j_{1.415209025} = 79.966464 = j_{72,1}$. Also

$$\begin{aligned} j_{72,2} &= 86.255443, & j_{1.415209,27} &= 86.250448, \\ j_{72,1} &= \underline{79.966464}, & j_{1.415209,25} &= \underline{79.966464}, \\ & \quad 6.288979 & & \quad 6.283984 \end{aligned}$$

$$D(72) = (j_{72,2} - j_{72,1}) - (j_{\mu,27} - j_{\mu,25}) = 6.288979 - 6.283984 = +0.004995.$$

Now use 71 for the approximation.

$$\begin{aligned} j_{71,2} &= 85.196177, & j_{0.75076,27} &= 85.215054, \\ j_{71,1} &= \underline{78.931722}, & j_{0.75076,25} &= \underline{78.931722}, \\ & \quad 6.264455 & & \quad 6.283332 \end{aligned}$$

$$D(71) = 6.264455 - 6.283332 = -0.018887.$$

These calculations show that $\bar{\nu}$ lies between 71 and 72, $\bar{\mu}$ lies between 0.5 and 1.5 and the zeros are between 78 and 80 and 85 and 87. These approximations in the computer program gave the results $\nu = 71.87224$, $\mu = 1.33143$, $j_{\nu,1} = j_{\mu,25} = 79.83629$, $j_{\nu,2} = j_{\mu,27} = 86.12017$.

(b) In order to find more pairs of such Bessel functions, suppose that the interval $[j_{\mu,25}, j_{\mu,27}]$ is replaced by $[j_{\mu,26}, j_{\mu,28}]$. It will be shown that this does not lead to values such that $D(\nu_1)$ and $D(\nu_2)$ have opposite signs. Taking $\mu = 0$, $j_{0,26} = 80.897556$. If $j_{\nu_0,1} = j_{0,26}$, $\nu_0 = 72.900085$. Then

$$\begin{aligned} j_{\nu_0,2} &= 87.208432, & j_{0,28} &= 87.180630, \\ j_{\nu_0,1} &= \underline{80.897556}, & j_{0,26} &= \underline{80.897556}, \\ & \quad 6.310876 & & \quad 6.283074 \end{aligned}$$

$$D(\nu_0) = +0.027802.$$

Similar calculations yield $D(74) = 0.05410$. It becomes impossible to find a negative value. Hence to obtain further values, the ranks of the zeros of $J_\mu(x)$ must be decreased so that $[j_{\mu,24}, j_{\mu,26}]$ is the next interval to be considered. In this case similar methods lead to $\nu = 72.06767$, $\mu = 3.50186$, $j_{\nu,1} = j_{\mu,24} = 80.03849$ and $j_{\nu,2} = j_{\mu,26} = 86.81724$.

(c) This decreasing of the rank of the zeros of $J_\mu(x)$ leads to $[j_{\mu,4}, j_{\mu,2}]$ and stops there since $[j_{\mu,3}, j_{\mu,1}]$ must have $j_{\mu,1} = j_{\nu,1}$, which implies $\mu = \nu$ contrary to Theorem 2. However if the case $[j_{\mu,10}, j_{\mu,12}]$ is calculated, then $655 < \nu < 657$, $582 < \mu < 585$, and the zeros lie between 671 and 674 and 683 and 686. (Since $J_{100}(x)$ is the function of largest order for which the computation of Bessel functions is validated, it is not possible to carry out this determination by the computer program.) The next case $[j_{\mu,9}, j_{\mu,11}]$, however, is quite different. In this case $D(\nu) < 0$ for all ν. The following table was found:

ν	800	1,000	2,000	6,000	20,000	100,000	400,000	1,000,000
$D(\nu)$	-0.357	-0.335	-0.281	-0.231	-0.214	-0.248	-0.335	-0.432

Hence decreasing the rank fails to yield new pairs before the extreme limit is reached.

7. General Method of Approximation. Suppose n intervals of $J_\nu(x)$ cover m intervals of $J_\mu(x)$ and $j_{\nu,k}$ is the smallest zero of $J_\nu(x)$ belonging to the n intervals. The m intervals of $J_\mu(x)$ will have $j_{\mu,h+m} - j_{\nu,h}$ very nearly equal to $m\pi$ if μ is small. Determine ν so that $j_{\nu,k+n} - j_{\nu,k} < m\pi$ but $j_{\nu+1,k+n} - j_{\nu+1,k} \geqslant m\pi$. This fixes $j_{\nu,k}$. Now, from tables of $j_{0,s}$ in [3], find the nearest $j_{0,h}$ to $j_{\nu,k}$ but $j_{0,h} < j_{\nu,k}$. This fixes h. From the sequence of values of $j_{0,h}, j_{1/2,h}, j_{1,h}$, etc. in the tables [3] find the values $j_{\mu,h}$ and $j_{\mu+1/2,h}$ nearest to $j_{\nu,k}$. Then by interpolating and calculating zeros μ can be determined so that $j_{\mu,h} = j_{\nu,k}$ to a close approximation. From these results $j_{\nu,k+n}$ and $j_{\nu,h+m}$ can be found and thus $D(\nu)$ can be calculated. If $\mu \geqslant 1/2, j_{\mu,h+m} - j_{\mu,h} \geqslant m\pi$ and $j_{\nu,k+n} - j_{\nu,k}$ was fixed so as to be $\leqslant m\pi$. In this case $D(\nu)$ will always be < 0. If ν is increased, keeping m, n, h, k the same, it may be that $D(\nu + 1) > 0$, and a pair of functions with two common zeros will be determined. If $D(\nu + 1) < 0$, try $D(\nu + 2)$ etc. As example (c) in Section 5 shows there are cases where $D(\nu)$ stays < 0 no matter how large ν becomes, in which case no pair of functions is found. If $\mu < \frac{1}{2}$ it may result that $D(\nu) > 0$. In this case changing ν to $\nu - 1$ (not changing any of m, n, h, k) may give $D(\nu - 1) < 0$ and determine a pair of functions with two common zeros. As example 6(b) shows $D(\nu)$ can remain > 0 for all ν, and in this event no pair of suitable functions will be found.

Suppose that the first case mentioned in the previous paragraph occurs. Then $j_{\nu,k+n} - j_{\nu,k} < m\pi$ but $j_{\nu+1,k+n} - j_{\nu+1,k} > m\pi$. Now change the rank h of $j_{\mu,h}$ to $h + 1$. Then there will be a new value ν' so that $j_{\nu',k} = j_{\mu,h+1}$. Since $j_{\mu,h+1} - j_{\mu,h} > \pi$ $(\mu > \frac{1}{2})$ and from the properties of the curves C_s discussed in Section 3, $1 < j_{\nu+1,k} - j_{\nu,k} < \pi/2$. So it follows that $\nu' \geqslant \nu + 2$. Then $j_{\nu',k+n} - j_{\nu',k} > j_{\nu+1,k+n} - j_{\nu+1,k} > m\pi$. Also $j_{\mu,k+1+m} - j_{\mu,k+1} < j_{\mu,k+m} - j_{\mu k}$ since $\mu > \frac{1}{2}$. Then $D(\nu') > 0$. Even if $\mu \leqslant \frac{1}{2}$, $j_{\mu,h+m+1} - j_{\mu,h+1} < m\pi$ and $D(\nu') > 0$. Notice that increasing ν makes the first parentheses of $D(\nu)$ increase, while the second parentheses cannot increase beyond $m\pi$, so that $D(\nu)$ is always positive. Therefore most cases of suitable pairs of Bessel functions can be obtained only by decreasing the rank h.

If h is decreased, new cases may result until the case $h = k + 1$ is reached. The process stops here because $h = k$ would require $j_{\nu,k} = j_{\mu,k}$, and this implies $\mu = \nu$, which is not true by Theorem 2.

8. Comments on the Approximations. In order to obtain one set of approximations for determining a pair of Bessel functions $J_\nu(x)$ and $J_\mu(x)$ with two zeros in common, at least eight zeros of the functions are needed, four to find a place where $(j_{\nu,k+n} - j_{\nu,k}) - (j_{\mu,g+m} - j_{\mu,g}) < 0$ and four where this difference is > 0. The uniform asymptotic formulae of F. W. J. Olver enables one to calculate the zeros very easily and without them this work could never have been carried out.

A limitation on all the calculations here is imposed by the fact that our large computer program for calculation of Bessel functions is only guaranteed to produce correct results for orders not exceeding 100. In order to determine how many cases arise, it is necessary to have a table of zeros of $J_{100}(x)$. This has been computed using three terms of Olver's series, so the values are correct to 8 places of decimals at least.

13.	165.98245 03531	26.	214.17646 28640

Consider the case of three intervals covering four $4\pi = 12.56637$ and $j_{100,11} - j_{100,8} = 12.54123$. To cover four intervals with any $J_\mu(x)$ with $\mu > \frac{1}{2}$ it will be necessary to take $\nu > 100$. But $j_{100,10} - j_{100,7} = 12.83442$ and this will cover four intervals. So all cases from $j_{\nu,4}, j_{\nu,1}$ up to $j_{\nu,10}, j_{\nu,7}$ must be considered. By this method it is possible to find limits for any given m and n keeping $\nu \leqslant 100$.

9. Other Problems. Perhaps the most interesting problem raised by this work is the question as to whether or not two Bessel functions can have more than two zeros in common. If a pair with three common zeros exists, they will of course have three cases of having pairs in common, so that if a complete list of pairs could be made, there would be three cases where for the same pair of values of ν and μ there would be entries in the list. This suggests that the list be arranged so that the order ν is in ascending order, and then that one looks at the values of μ to see if any pairs are the same. This was done with the values in the table and no pairs were found. Of course this suggests that it is not possible for two Bessel functions of the first kind to have more than two zeros in common, but it is also possible that the covering ratio m to n has not been extended far enough to make such a case occur. So it seems that there is not enough evidence to make a conjecture at this time.

Another question is whether there could be a third $J_\lambda(x)$ which also has the same two zeros as $J_\mu(x)$ and $J_\nu(x)$. If $j_{\nu,k} = j_{\mu,g}$ and $j_{\mu,g}$ is large enough, it is easy to see that $\lambda < \mu$ can be determined so that $j_{\lambda,i} = j_{\mu,g}$, but can it be found so that the second common zero is also a zero of $J_\lambda(x)$?

Another interesting question is the number of cases of pairs of Bessel functions with common pairs of zeros. It is obvious that the method outlined in this paper will produce at most a countable set of such functions. However, it is not proved that this method of obtaining the pairs of functions necessarily produces all of them.

10. Acknowledgments. Thanks for support from the Mathematics Department and the Computation Center of the Pennsylvania State University are gratefully given. Special thanks are due to H. D. Knoble for assistance in working the computer and for preparing programs and arranging the tables.

11. Tables of Those Bessel Functions Which Have Two Zeros in Common. In these tables u, v correspond to ν, μ in the above explanation, and a, b, c, d are used for the ranks of zeros. The calculations of the exact values were done by the large computer and entered on punch cards, which were then used to print the table. This avoids the difficulties of copying and proofreading.
