

Compact and Low-profile Textile EBG-based Antenna for Wearable Medical Applications

A.Y.I. Ashyap, Z. Z. Abidin, *Member, IEEE*, S. H. Dahlan, *Member, IEEE*, H. A. Majid, *Member, IEEE*, S.M. Shah, M. R. Kamarudin, *Senior Member, IEEE*, A. Alomainy, *Senior Member, IEEE*.

Abstract — A compact wearable antenna with a novel miniaturized EBG structure at 2.4 GHz for medical application is presented in this letter. The design demonstrates a robust, compact and low-profile solution to meet the requirements of wearable applications. The EBG structure reduces the back radiation and the impact of frequency detuning due to the high losses of human body. In addition, the structure improves the front-to-back ratio (FBR) by 15.5 dB. The proposed compact antenna with dimensions of $46 \times 46 \times 2.4 \text{ mm}^3$ yields an impedance bandwidth of 27% (2.17-2.83 GHz), with a gain enhancement of 7.8 dBi and more than 95 % reduction in the SAR. Therefore, the antenna is a promising candidate for integration into wearable devices applied in various domains, specifically biomedical technology.

Index Terms— Artificial ground plane, electromagnetic band gap (EBG), flexible antennas, specific absorption rate (SAR), wearable textile.

I. INTRODUCTION

IN recent years, increasing interests have been placed on the area of wearable computing systems due to the potential applications in several areas, ranging from health monitoring for elderly/ children, observing human vital signs, physical training, tracking and emergency rescue systems [1]. An antenna plays a vital role in a wearable device. Since such antenna is within a close proximity to the human body with its various curvatures and complexities, the antenna performance must take into account the structural bending, mismatch and losses caused by the body, while at the same time, sustains optimum performance. At the same time, the wearable antenna has to be low-profile, robust and light-weight. The radiation from the wearable antenna should present the least specific absorption rate

(SAR) [2] inside the human tissue to adhere to the health and safety requirements. This is applied for several antenna orientations and separation distances from the body.

In the open literature, several designs have been presented and examined for their appropriateness as a wearable antenna element that includes cavity-backed [3], microstrip [4], inverted-F [5], planar and vertical monopole antennas [6, 7]. However, these antennas have narrow bandwidth, large footprint, high front-to-back ratio and suffering from protrusion from the body.

Alternatively, electromagnetic band gap (EBG) structures are introduced in wearable antenna designs to provide a high degree of isolation from the human body and reduce the SAR in the tissues. However, such structures still suffer from the fact that most EBG-based designs are electrically large [8] - [10], and experiences poor front-to-back ratio [11].

TABLE I
 SUMMARY OF THE DIMENSION, THE NUMBER OF UNIT CELLS, DIRECTIVITY PER BANDWIDTH, AND SAR PER DISTANCE VALUE OF THE LITERATURE AT 2.4 GHz

Ref	Dimensions (mm ³)	Number of unit cell	Directivity (dBi) / BW (%)	SAR(w/kg)/ distance from body	
				1g	10g
[9]	150×150×4	3×3	N/A/5.08	N/A	0.016/1
[10]	120×120×4.3	3×3	6.4/4	0.079/5.3	0.043/5.3
[12]	100×100×6	2×2	2.42/9.85	N/A	0.072/15
[13]	100×100×4.5	4×4	2.5/N/A	N/A	0.046/10
proposed	46×46×2.4	2×2	7.8/27	0.0368/1	0.0138/1

Textile antennas integrated with EBG structures at 2.4 GHz have been reported in [9]-[10], [12]-[13]. Table I summarizes the work in terms of antenna dimensions, directivity, and SAR performance. From the table, it is evident that the size of the antennas is still large.

In this letter, a low-profile antenna integrated with a compact EBG structure for medical applications is presented. The dimensions are $46 \times 46 \times 2.4 \text{ mm}^3$, which demonstrates further size reduction as compared to the previously published work (see Table I) but do not compromise on the performance. The EBG structure is used to produce phase reflection and suppress the surface wave which significantly improve the gain and front-to-back ratio of the antenna and reduces the SAR and consequently, widened the bandwidth.

The design and characterization of the antenna and EBG structure are presented in Section II. In Section III, the analysis of the antenna on EBG plane is discussed. Finally, Section IV examines the antenna-body operation in terms of the reflection coefficient, S_{11} , structural bending and SAR.

II. ANTENNA AND EBG DESIGN

A. Antenna Design

The proposed inverse E-shaped microstrip monopole antenna is designed numerically by using CST Microwave Studio® [14], to operate at the ISM band of 2.4 GHz. The antenna is mounted on a 0.7-mm thick denim material as a substrate with a dielectric constant of 1.7 and loss tangent of 0.02 as illustrated in Fig. 1(a). The overall dimensions of the antenna are $30 \times 20 \times 0.7 \text{ mm}^3$ which clearly highlights the compactness of the design as compared to the existing antennas. The conducting material used is ShieldIt Super conductive textile from LessEMF Inc. [15] with thickness of 0.17 mm and an estimated conductivity of $1.8 \times 10^5 \text{ S/m}$ is used to form the metallic layers [13].

B. EBG Design

In order to achieve a compact EBG structure, a unique square loop patch with four T-shaped connected as strip line pattern is chosen. As mentioned in [16], in order to obtain a compact size, more inductance needs to be introduced into the design. Hence, a strip line pattern is proposed to represent the inductance. The topology of the EBG array is shown in Fig. 1(b). An optimum of 2×2 EBG array is chosen and placed on a denim material with overall dimensions of $46 \times 46 \times 0.7 \text{ mm}^3$. The EBG acts as an artificial magnetic conductor (AMC) when its reflection phase varying from -180° to $+180^\circ$ and band gap when it is capable to suppress the surface wave at certain operational frequencies.

The analysis of EBG characteristics are performed by using two methods which are the reflection phase and suspended transmission line [17] to validate its performance at the required operating frequency. Fig. 2 depicts the results of the EBG characteristics based on these two methods. It

can be observed that the proposed EBG structures can reflect a normally incident electromagnetic wave with a zero phase shift at a frequency of 2.4 GHz which shows the PMC-like characteristic where the PMC characteristic is not exist in nature, while the suspended line examined the band gap of the EBGs from 1.91 - 2.68 GHz (for $S_{21} \leq -10 \text{ dB}$).

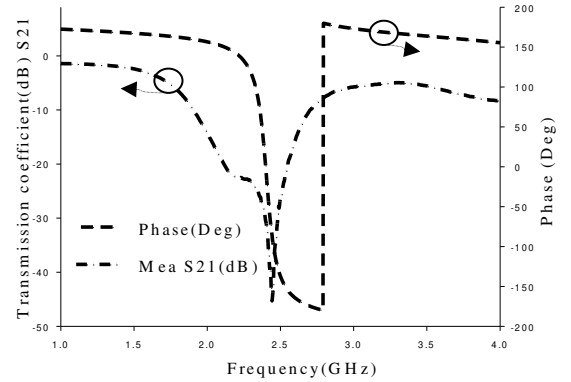

Fig. 2. EBG characteristics based on reflection phase and suspended line.

III. ANTENNA ON EBG STRUCTURE

The antenna is placed above the EBG structure as can be viewed in Fig. 3. A 1-mm thick Rohacell foam is employed as a spacer between the antenna and EBG in order to reduce the mismatch and any electrical contacts to prevent from short circuit. It is a highly flexible foam that will take the shape of the surrounding materials it is attached to and will ensure minimum changes to the structure of the antenna applied. Under close inspection, it is found that the foam does not leave much gaps between the substrates.

Fig. 3. Configuration of antenna with EBG structure.

The simulated and measured reflection coefficients of the antenna in free space, with and without the EBG structure, are compared as can be seen in Fig. 4. From the figure, the measured band range of the antenna without the EBG structure is from 2.23 GHz to 2.59 GHz with a bandwidth of 360 MHz (15%). Meanwhile, the proposed antenna incorporated with EBG effectively enhanced the measured operating bandwidth from 2.17 GHz to 2.83 GHz with a bandwidth of 660 MHz (27%). From both results, a good impedance matching is observed with a slight shift in the resonant frequency when the EBG is incorporated. This can be attributed to the inconsistency in the fabrication process and soldering tolerance.

The simulated and measured radiation patterns of the antenna with and without the EBG structure at the E-plane and H-plane are compared as depicted in Fig. 5. The measurement is conducted in the anechoic chamber in the

UTHM. From the results, a good agreement is shown between the simulated and measured results. The addition of EBG structure reduces the radiation into the human body by at least 15.5 dB as compared to the antenna by itself and enhances the directivity by up to 7.8 dBi in a direction away from the body.

IV. PERFORMANCE OF THE DESIGN ON BODY

A. Effects of Human Tissues on Reflection Coefficient

A comparison between the simulated and measured reflection coefficients of the antenna, with and without the EBG structure, is performed to examine the impact of lossy human tissue. A multilayer model with an outer radius of 40 mm [20] is used to imitate the human tissue model. The model consists of four layers with each layer representing the skin, fat, muscle, and bone. The thickness, permittivity,

conductivity, and density of each layer are listed in Table II [21]. The fabricated prototypes were measured on the arm of a male volunteer, who weighs 80 kg and has a height of 160 cm. The arm radius was 40mm. The results can be seen in Fig. 6. From the figure, it can be observed that removing the EBG structure causes the shifting of the resonant frequency to the lower band due to the high dielectric nature of human tissue that also influences the response of the antenna which result in the attenuation and detuning [9]. On the contrary, with the presence of EBG, the demanded bands of operation are achieved due to high isolation provided by the EBG between the body and antenna.

B. Bending Evaluation

The performance of the antenna under deformation is analyzed in this section. In order to do so, a bending of the antenna with EBG structure over a foam cylinder along the y-axis and x-axis in varying diameters (in mm), that correspond to the approximate human arm has been modeled. This is to ensure the frequency of operation is sustained under the bending condition as can be seen in Fig. 7. From the figure, the resonant frequency and bandwidth are similar although the diameter of the cylinder is varied.

Fig.7. Reflection coefficient (S11) of antenna with EBG structure for different bending diameters (in mm) at the (a) y-axis and (b) x-axis

TABLE II
MULTILAYER HUMAN MODEL [21]

Layer	Thickness (mm)	ϵ_r	Conductivity σ (S/m)	Density (kg/m ³)
Skin	2	37.95	1.49	1001
Fat	5	5.27	0.11	900
Muscle	20	52.67	1.77	1006
Bone	13	18.49	0.82	1008

C. Specific Absorption Rate Evaluation

The SAR level of the antenna, with and without the EBG structure, needs to be analyzed in the design stage to ensure the safety limit is obeyed. According to the guidelines by the FCC and CNIRP, the SAR must not be greater than 2 W/kg averaged over 10 g and not greater than 1.6 W/kg averaged over 1 g of human tissues [18 - 19].

The same multi-layer model that was explained in the previous section was used for SAR analysis. The model consists of four layers with each layer representing the skin, fat, muscle, and bone. The thickness, permittivity, conductivity, and density of each layer are listed in Table II [21].

The input power to the antenna to calculate the SAR is selected at 100 mW as a benchmark. In addition, to emulate the practical antenna to skin distances in fabric, a 1 mm distance between the antenna with EBG structure and the multilayer model tissues are used. The calculation of SAR is based on the IEEE C95.1 standard provided in the CST MWS software.

As shown in Table III, the SAR values of the antenna with EBG structure obey both standards. The reduction is more than 95% and is compared with the previous published data as shown in Table I.

TABLE III
SAR VALUES WITH AND WITHOUT EBG

Averaged value	SAR without EBG (w/kg)	SAR with EBG (w/kg)
1 g	6.19	0.0368
10 g	2.70	0.0138

V. CONCLUSION

A novel compact wearable antenna with a miniaturized EBG structure for medical applications is successfully designed, simulated and measured. The EBG structure is used to eliminate the mismatch and frequency shifting caused by the human body. In addition, the presence of the EBG structure reduces the unwanted radiation towards the human body. The bending do not affect the resonant frequency and bandwidth of the antenna. The proposed design exhibits an operating bandwidth of 27% and a gain of 7.8 dBi at 2.4 GHz. The front-to-back ratio improves by 15.5 dB. Furthermore, the calculated SAR values are low and obey the limit stipulated in the FCC and CNIRP regulations. Thus, the proposed antenna with EBG structure is a strong potential candidate for wearable medical applications.
