**Keywords:** Durum Wheat; Heat Stress; Wheat Kernel Proteome; Wheat Kernel Metabolic Proteins

**ABSTRACT**

In Central and Southern Italy, where durum wheat represents one of the most widely cultivated crops, grain filling occurs during Spring, a period characterised by sudden increases in temperature.

Wheat grain proteins are classified into albumins, globulins, and prolamins. The non-prolamin fractions include proteins with metabolic activity or structural function.

In order to investigate the consequences of heat stress on the accumulation of non-prolamin proteins in mature durum wheat kernels, the Italian cultivar Svevo was subjected to two thermal regimes (heat stress *vs.* control) during grain filling. The 2D patterns of non-prolamin proteins were monitored to identify polypeptides affected by heat stress. This study shows that heat stress alters significantly the durum wheat seed proteome, although the fold changes range only between 1.2 and 2.2. This analysis revealed 132 differentially expressed polypeptides, 47 of which were identified by MALDI TOF and MALDI-TOF-TOF MS and included heat shock proteins, proteins involved in the glycolysis and carbohydrate metabolism, as well as stress related proteins. Many of the heat induced polypeptides are considered to be allergenic for sensitive individuals.

The differences observed with previously reported data regarding bread wheat may be explained by the absence of the D genome in durum wheat.

## INTRODUCTION

1  
2  
3  
4  
5  
6  
7  
8  
9  
10 Wheat is a widely used cereal for human consumption. The two most important cultivated wheat  
11 species are *Triticum aestivum* L. (bread wheat) and *T. durum* Desf. (durum wheat). *T. aestivum* is a  
12 hexaploid species possessing the genomes AABBDD, whereas *T. durum* is tetraploid with genome  
13 composition AABB. This last species is extremely important, in the Mediterranean areas, where  
14 represents the most widespread crop, finding large utilization in the production of a wide range of  
15 end products, such as pasta, leavened and unleavened breads, cous cous etc. Genes present on D  
16 chromosomes, such as those determining flour texture [1] or those encoding specific high molecular  
17 weight glutenin subunits [2], missing in durum wheat, confer the typical bread-making properties to  
18 bread wheat flour. In addition, the absence of the D genome in durum wheat may affect also the  
19 response to biotic and abiotic stresses, because it has been shown that several stress-related genes  
20 are located on the D genome [3,4].

32  
33  
34

35 Abiotic stresses, such as drought, salinity, extreme temperatures, chemical toxicity, and oxidative  
36 stress are serious threats to agriculture because they affect quality properties, including yield, and  
37 the characteristics of the final product. These effects stem from altered synthesis and functionality  
38 of specific protein [5]. Proteome analysis is an effective tool for investigation of changes in protein  
39 accumulation in wheat kernel in response to heat stress [6].  
40  
41  
42  
43  
44  
45  
46  
47

48 The seed protein content is the most important factor determining wheat quality. Wheat kernel  
49 proteins are divided according to their solubility properties into prolamins (gliadins and glutenins,  
50 collectively known as gluten proteins), soluble in diluted acid or alkali or alcohol-water mixtures,  
51 and albumins and globulins, which are water and salt soluble, respectively [7]. Gluten proteins  
52 represent about 80% of wheat seed proteins, and are the most important determinant of the dough  
53 properties.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 High temperature during the grain filling has been reported to alter the yield and the dough quality  
4 of bread wheat [8,9]. Heat stress, in fact, modifies the ratio between the different gluten proteins in  
5 the seed by affecting mainly the composition of the polymeric fraction (soluble/insoluble  
6 polypeptides) [10]. High temperatures thus favor synthesis of gliadins, whereas glutenin synthesis  
7 decreases. An explanation of the gliadin increase after heat stress might be related to the presence of  
8 heat stress elements (HSE) in the upstream regions of some gliadin genes [10]. Because glutenins,  
9 however, are the most important polypeptides in determining quality properties, their decrease,  
10 coupled to the relative increase of gliadins, might explain the negative performance of bread wheat  
11 exposed to high temperatures.  
12

16  
17  
18  
19  
20  
21  
22  
23

24 Water-soluble albumins and salt-soluble globulins constitute about 20% of total flour protein  
25 [11,12]. The non-prolamin proteins have mainly metabolic activity or structural functions [13].  
26  
27  
28

29 Certain wheat globulins, however, are reported to be storage proteins [14,15]. In contrast to gliadins  
30 and glutenins, albumins and globulins have been less thoroughly characterized, most probably due  
31 to their minor role in wheat quality compared to gluten proteins, although the ratio of albumin to  
32 globulin has been reported to correlate with bread-making quality [11]. A relationship between the  
33 water-soluble  $\alpha$ -amylase/trypsin inhibitors and pasta quality has also been suggested [16,17]. The  
34 soluble proteins from wheat seeds are now receiving increasing attention because several  
35 polypeptides from this fraction have been identified as human allergens [18].  
36

40  
41  
42  
43  
44  
45

46 Effects of heat stress on metabolic proteins in wheat kernel were previously studied in bread wheat  
47 kernels. One of the consequences was a reduction in starch accumulation and activity of soluble  
48 starch synthase [19-21]. More recently, proteome analysis of bread wheat showed the involvement  
49 of enzymes in starch biosynthesis, e.g. glucose-1-phosphate adenylyltransferase and the granule  
50 bound starch synthase in heat stress response. In addition, up-regulation of a large number of  
51 cytoplasmic heat shock proteins (HSP) was confirmed [6].

56  
57  
58  
59  
60

1  
2  
3 Very recent investigations have shown that environmental changes, such as heat, cold, drought, and  
4 waterlogging mainly affect storage proteins of the 7S globulin (vicilin-like) and R-globulin  
5 families, along with defense proteins such as serpins and chitinases [22].  
6  
7

8  
9  
10 Durum wheat is mostly grown in the Mediterranean region where heat stress during grain filling is a  
11 likely event. In order to understand the response of the metabolic protein fraction to heat stress and  
12 make a comparison with bread wheat, we have used proteome analysis to identify the durum wheat  
13 soluble seed proteins that are influenced by heat stress and which may affect the nutritional and  
14 technological quality of the derived products.

## 25 MATERIALS AND METHODS

### 26 27 28 29 **Plant material and heat treatment**

30  
31  
32  
33  
34 Durum wheat (*cv* Svevo) was grown in a climate chamber in a medium composed of soil, sand, peat  
35 (6:3:1) at 10°C (9 h day)/ 7°C (15 h night) with 60% relative humidity and photon flux of 500  $\mu\text{mol}$   
36  $\text{m}^{-2} \text{s}^{-1}$  until appearance of the third leaf. At this point, conditions were gradually (according to the  
37 development stage) switched to 20°C (13 h day)/ 17°C (11 h night) with 55% relative humidity and  
38 photon flux of 500  $\mu\text{mol} \text{m}^{-2} \text{s}^{-1}$ . These conditions were maintained until five days after anthesis.  
39  
40  
41  
42  
43  
44

45  
46 Then, while control plants were maintained in the same conditions, stressed plants were subject to  
47 heat-shock treatment, carried out at 37/17 °C (13 h day/11 h night) with 55% relative humidity for 5  
48 days. Following the heat shock, the temperature was decreased to 28°C for 4 h, and then the  
49 growing cycle was set up at 20°C (13 h day)/ 17°C (11 h night) with 55% relative humidity and 500  
50  $\mu\text{mol} \text{m}^{-2} \text{s}^{-1}$  photon flux. Starting from the milk maturity stage, both control and stressed plants  
51 were brought to complete maturity at 25°C (16 h day)/ 20°C (8 h night) with 45% relative humidity.  
52  
53  
54  
55  
56  
57  
58  
59  
60 In both control and stress treatments, seeds were collected from four biological replicas.

## Protein content analysis and selective extraction

The seed protein content was determined by Kjeldahl nitrogen analysis (Nx5.7). Metabolic seed proteins were extracted according to [23], but amounts were scaled up in order to perform larger 2D gels. Briefly flour (150 mg) was suspended in 600  $\mu$ l of cold KCl buffer (50 mM Tris-HCl, 100 mM KCl, 5 mM EDTA, pH 7.8). The suspension was incubated on ice for 5 min with intermittent mixing and centrifuged (14,500g, 15 min, 4 °C). The KCl-soluble fraction was collected and 5 volumes (v/v) of cold 0.1 M ammonium acetate in methanol were added at room temperature. Following incubation overnight at -20 °C, the methanol-insoluble fraction was pelleted by centrifugation as above. The pellet (containing metabolic proteins) was rinsed with cold acetone, dried down and stored at -20°C until further use.

## 2-DE

Metabolic proteins were dissolved in 800  $\mu$ l of strip rehydration buffer containing 7 M Urea, 2 M thiourea, 2% (w/v) CHAPS, 2% (v/v) Triton X100, 1.2% (v/v) Destreak reagent (GE Healthcare), and 0.5% (v/v) IPG buffer pH 3–10. IEF linear IPG strips (18 cm, GE Healthcare) pH 3–10 were used as first dimension. Strips were rehydrated overnight at 20°C with 200  $\mu$ L of dissolved proteins (about 300  $\mu$ g protein) and 150  $\mu$ l of rehydration buffer was added. The same extract volume (200  $\mu$ L) was loaded. Focusing was performed at 20°C for 80 kVh (200 V 4 h, 500 V 2.5 h, 1000 V 3 h, 5000 V 2 h, 8000 V 9 h). The gel strips were subsequently equilibrated for 25 min in 0.1 M Tris-HCl pH 8.8 containing 6 M Urea, 30% (w/v) glycerol, 2% (w/v) SDS, 1% (w/v) DTT and bromophenol blue as tracking dye. For the second dimension, the strips were transferred onto 18  $\times$  20 cm polyacrylamide gels (15%T, 1.28%C) (Protean II X-Cell, BioRad) and run at 40 mA *per gel* for 3–4 h at 11°C until the dye front left the gel.

1  
2  
3 After electrophoresis, proteins were visualized by CBB staining according to [24]. All gels were  
4 stained for 16 h and destained for 1 h with distilled water before image acquisition. Three technical  
5 replicas were performed for each of the four biological replicas from each treatment, giving a total  
6 of 24 gels. Destained gels were scanned with Image Master LabScan (GE Healthcare) and analyzed  
7 using the software SameSpots Progenesis (vers. 1.0.2602.33289, Nonlinear Dynamics, UK). This  
8 software includes statistical analyses such as ANOVA ( $p \leq 0.05$ ), determination of False Discovery  
9 Rate (FDR,  $q \leq 0.05$ ), and Principle Component Analysis (PCA) calculated according to [25].

### 20 21 22 **Protein identification by MALDI TOF-TOF** 23 24 25

26  
27 Protein identification was done by picking gel spots from two independent gels to minimize  
28 technical variability. CBB-stained spots were excised from the gel, cut to pieces and washed twice  
29 with 40% ethanol until colorless. The destained gel pieces were dehydrated with ACN, treated with  
30 10 mM DTT in 50 mM  $\text{NH}_4\text{HCO}_3$  for 1 h at 56°C and finally alkylated with 55 mM iodoacetamide  
31 in 50 mM  $\text{NH}_4\text{HCO}_3$  for 30 min in the dark. Gel pieces were dehydrated with ACN, rehydrated  
32 with 1 pmol trypsin (Sigma) solution in 50 mM  $\text{NH}_4\text{HCO}_3$  and incubated at 37°C overnight for  
33 digestion. The peptides were extracted twice from gel slices with 5% formic acid in 50% ACN. The  
34 peptide solution was then desalted, concentrated and applied to an Anchorchip target™ (Bruker  
35 Daltonics) using  $\alpha$ -cyano-4-hydroxycinnamic acid as matrix, according to the manufacturer's  
36 instructions and [26]. Mass spectrometric analysis was performed on a MALDI TOF-TOF Ultraflex  
37 II in positive ion reflector mode and spectra were processed and analysed using the software  
38 FlexAnalysis and BioTools (Bruker Daltonics). Database searching was carried out using an in-  
39 house MASCOT server (Matrix Science, London, UK) to search NCBIInr  
40 (<ftp://ftp.ncbi.nih.gov/blast/db/>) and the Wheat Gene Index  
41 (<http://compbio.dfci.harvard.edu/tgi/tgipage.html>) release 10.

1  
2  
3 Proteins were identified by PMF. Matrix contaminants and predominant keratin peaks were  
4 removed from peak lists using PeakErazor  
5  
6  
7  
8 (<http://www.protein.sdu.dk/gpmaw/Help/PeakErazor/peakerazor.html>). In order to identify a protein  
9 unambiguously the following criteria were used: MASCOT score with  $p \leq 0.05$ ; protein sequence  
10 coverage  $> 15\%$ ; at least five independent peptides matching with a mass tolerance of 50 ppm and  
11 maximum one trypsin miscleavage site. The Oxidation (M) and the Gln->pyro-Glu were selected as  
12 variable fragment modifications. Where the PMF-based identification was uncertain, fragment ion  
13 spectra were obtained for at least three peaks with a signal:noise ratio  $> 5$  and  $m/z > 1400$ . Each  
14 fragment ion spectrum was checked against the same database as used for PMF and the  
15 identification was confirmed if correspondence was found.

## 31 RESULTS AND DISCUSSION

32  
33  
34  
35  
36  
37 Heat stress can be an important factor affecting yield and quality of durum wheat Although quality  
38 is mostly determined by gluten proteins, that are the major protein components of wheat seeds, also  
39 the soluble metabolic protein fraction (albumins and globulins) plays a role, especially in terms of  
40 nutritional/antinutritional properties. Most of these polypeptides, in fact, show allergenic properties  
41 in sensitive individuals [18]. Albumins and globulins are distributed mainly in the outer layers of  
42 wheat kernels, and thus are important components in whole-wheat flours and semolina, towards  
43 which there is an increasing consumer interest, because they have a higher amount of fibers,  
44 proteins and functional components [27].  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55

56 In the present paper the durum wheat cultivar Svevo, widely grown in Italy and moderately resistant  
57 to cold stress, was subjected to two thermal regimes, *i.e.* heat stress and control conditions during  
58  
59  
60

1  
2  
3 grain filling. The effect on the metabolic protein fraction was analysed by comparison of the  
4  
5 corresponding proteomes.  
6

7  
8 Firstly, protein contents were compared between stressed and control samples, which revealed that  
9  
10 heat stressed samples accumulated significantly higher amounts of protein. The protein content  
11  
12 being 19.30% ( $\pm 1.43$ ) in stressed and 13.85% ( $\pm 1.87$ ) in control samples ( $p=0.004$ ). A correlation  
13  
14 between heat stress and increase in protein content was previously reported in bread wheat [28]. In  
15  
16 our case, the increase in protein content was due mostly to gluten proteins, that were about 50%  
17  
18 more abundant in heat stressed samples with respect to control samples, whereas the metabolic  
19  
20 fraction increased by about 20% (data not shown).  
21  
22

23  
24 The highly reproducible 2-D gels showed about 1000 spots in the pI range 3–10 and comparison  
25  
26 revealed differential expression of proteins ( $1.2 < \text{fold change} < 2.2$ ) in 132 spots (Fig. 1), 65% were  
27  
28 up-regulated in heat-treated samples (Fig. 2). Because only those spots satisfying ANOVA ( $p < 0.05$ )  
29  
30 and FDR ( $q < 0.05$ ) values were chosen, and the Principal Component Analysis (PCA) performed on  
31  
32 the differentially expressed spots [25] indicated two separate groups corresponding to the two  
33  
34 thermal regimes (Fig. 3), we are confident that the observed differences are significant.  
35  
36  
37  
38  
39  
40

### 41 **Protein identification**

42  
43 MALDI TOF analysis identified 47 proteins from the picked varying spots (Table 1; Fig. 4).  
44

45  
46 Among the identified proteins, 85% were up-regulated and 15% down-regulated. Proteins identified  
47  
48 by mass spectrometry were classified based on to their main activity although most are involved in  
49  
50 different pathways or signaling.  
51  
52

53  
54 Noteworthy is the observation that the fold changes observed, are in a narrow range ( $1.2 > \text{fold}$   
55  
56  $\text{change} > 2.2$ ). This is in agreement with previous findings relative to the bread wheat cultivar Butte  
57  
58 86 [29].  
59  
60

1  
2  
3 As expected, heat stress increased expression of many proteins related to desiccation and oxidation  
4 stress, e.g. Late Embryogenesis Abundant (LEA)-proteins, the heat shock proteins HSP70 and  
5 HSP26 [5, 30-32]. These proteins, through binding or interaction with other proteins, prevent  
6 damage of proteins and cell membranes (reviewed in [33]). Also glyoxalase I, one of the enzymes  
7 of the glyoxalase pathway related to the detoxification pathway of methylglyoxal in plants [34] was  
8 up-regulated.  
9  
10  
11  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21

### 22 *Carbohydrate metabolism or energy related proteins*

23  
24 Nucleoside diphosphate kinase (NDPK), which is required for the synthesis of nucleotide  
25 triphosphate precursors of DNA and RNA, was up-regulated along with some housekeeping  
26 enzymes involved in glycolysis and the pentose phosphate pathway (glyceraldehyde 3-phosphate  
27 dehydrogenase, phosphoglycerate kinase, and glucose and ribitol dehydrogenase), in agreement also  
28 with that reported in [29], in which the effect of high temperature on soluble proteins of developing  
29 bread wheat grains has been studied. Altered expression pattern of NDPK was previously found in  
30 response to abiotic (including heat stress) and biotic stresses in rice and other plant species [35-36],  
31 suggesting that NDPK plays a regulatory role in addition to its primary metabolic functions.  
32  
33 Five spots (427, 444, 460, 503, 514) which were up-regulated by heat stress contained  
34 glyceraldehyde 3-phosphate dehydrogenase (GADPH), which is involved in glycolysis and has been  
35 identified as one of the allergens implicated in bakers' asthma [18]. Bustos and Iglesias [37]  
36 reported that wheat endosperm and shoot GAPDH undergoes posttranslational phosphorylation  
37 enabling interaction with 14-3-3 family proteins, thus exerting a regulation aimed at maintaining the  
38 levels of energy and reductants in the cytoplasm. Recently, it was established using a proteomics  
39 approach that GAPDH activity in *Arabidopsis* was inhibited by H<sub>2</sub>O<sub>2</sub>, suggesting that GAPDH is a  
40 direct target of H<sub>2</sub>O<sub>2</sub> and might have a role in mediating ROS signaling in plants [38].

57  
58  
59  
60

1  
2  
3 Three up-regulated spots (436, 470, 502) belonged to the glucose and ribitol dehydrogenase protein  
4 family.  
5

6  
7  
8 Among the polypeptides down-regulated after heat shock, ATP synthase  $\beta$  subunit (spot 110) was  
9 identified, in agreement with observations in bread wheat [6]. The decrease in amount of ATP  
10 synthase may affect energy-dependent processes involved in heat stress resistance. It has been  
11 reported that energy consuming processes are the primary cellular targets for a decreasing of ATP  
12 demand in response to stresses, such as anoxia [39], and it is known that heat shock and anoxia are  
13 abiotic stresses eliciting similar cellular responses [40].  
14

15 Also phosphoglycerate kinase (spot 109), glycoside hydrolase family 85 (spot 173), and fructose 6  
16 phosphate-phosphotransferase (spot 299), all involved in glycolysis, were down-regulated. The  
17 glycoside hydrolase family is present in essentially all living organisms and has been implicated in  
18 a diversity of roles, such as biomass conversion in microorganisms and activation of defense  
19 compounds, phytohormones, lignin precursors, aromatic volatiles, and metabolic intermediates [41].  
20 Phosphoglycerate kinase was previously found to be over-expressed in the nuclear proteome of  
21 Arabidopsis in the cold stress response [42].

### 42 *Stress related*

43  
44  
45 Two members of the heat shock protein family, HSP70 (spots 70, 426) and HSP26 (spot 497) were  
46 up-regulated after the heat stress. HSP70s have been linked to the development of acquired  
47 thermotolerance in heat stress, although they seem also to correlate with tolerance to low  
48 temperature stress [43]. HSP26 belongs to the family of small heat shock proteins (sHSP) exhibiting  
49 chaperone activity and thought to protect proteins from irreversible aggregation [44].  
50  
51  
52  
53  
54  
55  
56  
57

58 A polypeptide of the 14-3-3 protein family was slightly down-regulated by heat stress (spot 341).  
59 Also Hurkman *et al* [29] observed down-regulation of members of this protein family after heat  
60 stress in bread wheat. Transcripts encoding proteins belonging to the 14-3-3 family accumulate in

1  
2  
3 barley after biotic stresses [45,46] and in wheat a region of chromosome 4AL containing genes  
4  
5 coding for 14-3-3 is associated with a resistance QTL against specific fungal diseases [47]. The up-  
6  
7 regulated polypeptides after heat treatment moreover included flavonoid *O*-methyltransferase (spot  
8  
9 445), a 14-3-3-binding protein involved in production of antimicrobial secondary metabolites ,thus  
10  
11 showing a potential role in response to a pathogen attack in barley [48]. Furthermore these  
12  
13 compounds have antioxidants properties and could thus be involved in oxidative stress.  
14  
15

16  
17  
18 Serpins (*serine protease inhibitors*) were identified in multiple spots (89, 94, 395, 456) as up-  
19  
20 regulated in response to high temperature. The same observation was made by Hurkman *et al* [29].  
21

22  
23 Serpins, found in the soluble fraction of wheat seeds, undergo differential regulation in response to  
24  
25 environmental stress [49]. The serpins are widespread in the plant kingdom and represent up to 4%  
26  
27 of the total protein in the mature endosperm of cereal grains [50,51]. While the precise  
28  
29 physiological role of serpins remains unclear, their activity suggests that they are involved in  
30  
31 inhibition of endogenous proteases, or proteases from grain pests. Because of their high  
32  
33 concentration in the endosperm, serpins have potential to influence grain quality traits [52-54].  
34  
35

36  
37 Other proteins with a defense role have a modified expression profile in response to heat shock.  
38  
39 Such proteins are typically identified in multiple forms on 2-D gels [55] and include: tritins (spots  
40  
41 140, 222),  $\alpha$ -amylase inhibitors (spot 362), and some 14-3-3 related or binding proteins. Most of  
42  
43 these proteins besides having a metabolic role, are also considered as storage proteins. Furthermore,  
44  
45 some are also considered wheat grain allergens along with the serpins [56].  
46  
47

48  
49 Another enzyme found in response to the heat treatment is glyoxalase I (spot 508). The glyoxalase  
50  
51 system is a set of enzymes that carry out detoxification of methylglyoxal and other reactive  
52  
53 aldehydes that are produced during normal metabolism. In plants it has been demonstrated that  
54  
55 different kinds of stress, such as salt and metal stress, elicits enhance the expression of glyoxalase I  
56  
57 [57-59].  
58  
59  
60

1  
2  
3 LEA proteins (spots 483 and 484) were up-regulated and are involved in stress responses. They are  
4  
5 typically correlated with cellular dehydration in response to cold stress. Other LEA functions  
6  
7 include roles as antioxidants and membrane and protein stabilisers during water stress [60].  
8  
9 Finally, 1-Cys peroxiredoxin (spot 14), also observed to be up-regulated, has antioxidant and  
10  
11 chaperone activity [61].  
12  
13  
14  
15  
16  
17  
18

### 19 *Storage proteins*

20  
21 Up-regulated proteins with a storage role here identified in the heat response mainly belong to the  
22  
23 globulin-like protein family (spots 110, 232 350, 509, 511) or protein homologous to embryo  
24  
25 globulin (spots 58, 239, 468, 505). Spot 239 (Homologue to Embryo Globulin) was found to be  
26  
27 down-regulated by heat stress. A role for these proteins in thermotolerance is not known. They may  
28  
29 be directly related to heat stress response by an unknown mechanism or, indirectly, be a target for  
30  
31 other proteins involved in the heat shock response. This is in agreement with [29].  
32  
33  
34  
35  
36  
37

### 38 **CONCLUDING REMARKS**

39  
40  
41 The results here reported offer a picture of the consequences of heat stress occurring during grain  
42  
43 filling on the accumulation of the soluble proteins in the mature seeds of the widely grown Italian  
44  
45 durum wheat *cv* Svevo. The results provide a basis for understanding how this environmental  
46  
47 change influences on protein synthesis and consequently the metabolic and quality traits of the  
48  
49 durum wheat kernel. Moreover, since the durum wheat kernel is of primary interest because the  
50  
51 semolina obtained by crushing mature seeds is the basis of many products of common use, among  
52  
53 which pasta is the most important, it is critical to understand if the different types of stresses that  
54  
55 wheat plants can potentially undergo, may alter protein composition, and, consequently, qualitative  
56  
57 and nutritional properties of the derived products.  
58  
59  
60

1  
2  
3 In the present study 47 metabolic proteins were identified from the soluble seed fraction of durum  
4 wheat which were induced or repressed by heat shock. The fold changes observed were between 1.2  
5 and 2.2, and this was also in agreement with [29].  
6  
7

8  
9  
10 In agreement with previous studies performed in bread wheat cultivars [6,29,62] both HSP70 and  
11 LEA proteins were up-regulated in response to heat stress. Other proteins, such as ATP synthase  $\beta$   
12 subunit and nucleoside diphosphate kinase (NDPK) related to the energy metabolism also  
13 responded to heat treatment. This agrees also with the findings of Hurkman *et al* [29]. Interestingly,  
14 we did not find any difference in the level of expression of starch related enzymes, although this  
15 was a finding of Majoul *et al* [6] in bread wheat. This might be a result either of the different  
16 protein extraction procedures, or of a different protein turnover in the plant material, or the enzyme  
17 forms that are regulated in bread wheat may be coded by genes present on the D genome, that is  
18 absent in durum wheat.  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30

31 GAPDH, a housekeeping enzymes involved in glycolysis, was found to be up-regulated. Others  
32 recently suggested a relationship between this enzyme and certain abiotic stresses [63]. Proteins  
33 reported to be influenced by abiotic stresses, e.g. oxidative and drought stresses, and also found as  
34 differentially regulated in the present work include 14-3-3 proteins, serpins, LEA proteins, 1-Cys  
35 peroxiredoxin, glyoxalase I, and proteins with a storage function (e.g. globulin-like proteins).  
36  
37  
38  
39  
40  
41  
42

43 It is noteworthy that some of the differentially regulated proteins are considered as allergens ( $\alpha$ -  
44 amylase inhibitors, serpins, tritins, GAPDH) and were found to be up-regulated after heat stress,  
45 which obviously represents a disadvantage for sensitive individuals.  
46  
47  
48  
49

50 These results illustrate that there is a common network “response” to different types of abiotic  
51 stress, such as drought, oxidative, cold and heat stress.

For Peer Review

**Tab.1** Proteins responsive to heat shock identified by PMF and MS-MS analysis. The following criteria were used: MASCOT score ( $p < 0.05$ ), minimal coverage 13%, at least 6 independent peptides should match with a mass tolerance of 50 ppm and 1 miss cleavage site. The database search was applied in NCBI nr and TIGR wheat. For all the identifications three peptide fragmentations were done (MS-MS) and used in combination in the database search. The ANOVA value for each spot, the fold change of the normalized volumes between the spots in the control and heat stressed maps, the proteins names, accession numbers, the MASCOT scores, the protein coverage and the theoretical molecular weight of the proteins identified are reported.

**Fig. 1.** 2-D PAGE map of metabolic proteins in the 3–10 pH range: circles indicate the differential spots

**FIG 2** 2D-PAGE of the metabolic proteins that are differentially regulated after the heat treatment: the yellow selection is referred to spots down-regulated, whereas the black one to up-regulated (fold change between 1.2 and 2.2). In the map all other proteins not involved in the heat response have been removed.

**Fig. 3.** PCA representation in which differential spots relative to each gel analysed are reported.

Circles: heat stressed samples; squares: control samples. Numbers represent the differentially expressed spots.

**Fig. 4.** 2-D PAGE map of metabolic proteins in the 3-10 pH range: circles indicate the identified proteins by MALDI-TOF and MALDI-TOF-TOF
