SHORT GENOME REPORT

Open Access

Complete genome sequence of *Pseudomonas brassicacearum* strain L13-6-12, a biological control agent from the rhizosphere of potato

Christin Zachow^{1,2*}, Henry Müller², Jana Monk³ and Gabriele Berg²

Abstract

Pseudomonas brassicacearum strain L13-6-12 is a rhizosphere colonizer of potato, lettuce and sugar beet. Previous studies have shown that this motile, Gram-negative, non-sporulating bacterium is an effective biocontrol agent against different phytopathogens. Here, we announce and describe the complete genome sequence of *P. brassicacearum* L13-6-12 consisting of a single 6.7 Mb circular chromosome that consists of 5773 protein coding genes and 85 RNA-only encoding genes. Genome analysis revealed genes encoding specialized functions for pathogen suppression, thriving in the rhizosphere and interacting with eukaryotic organisms.

Keywords: Short genome report, *Pseudomonadaceae*, *Pseudomonas brassicacearum* L13-6-12, Potato rhizosphere, Volatile organic compounds, Biocontrol, Plant growth promotion, Secretion systems

Introduction

Pseudomonas brassicacearum strain L13-6-12 was isolated from the rhizosphere of a field grown potato plant [1]. L13-6-12 was selected as effective biological control agent with disease-suppressing effects against Rhizoctonia solani Kühn in treated lettuce and potato plants in greenhouse and field trials [2]. It has additional antifungal activity against the phytopathogenic fungi Alternaria alternata, Botrytis cinerea Pers. DSM5145, Penicillium italicum, Phoma betae, Sclerotinia sclerotiorum, Verticillium dahliae Kleb. V25 (all Ascomycota) and Rhizoctonia solani AG2-2IIIB and AG4 and Sclerotium rolfsii (Basidiomycota). This biocontrol activity is linked to the production of secondary metabolites, including 2,4-diacetylphloroglucinol and hydrogen cyanide. For various strains of plantassociated pseudomonads the production of antifungal metabolites like DAPG and recombinase genes were identified as the major trait for biological control of

Full list of author information is available at the end of the article

soilborne pathogens and plant root colonization [3]. Genes in L13-6-12 predicting functions for biocontrol include factors such as secreted proteases and comprehensive secretion systems. It also supports plant growth by nutrient delivery by phosphate solubilization, production of indole-3-acetic acid as well as by aminocyclopropane-1-carboxylate deaminase activity. Additionally, L13-6-12 copes with abiotic stresses such as desiccation and high salt concentrations. To gain insight into ecological relevant traits and to improve its biotechnological applications we sequenced the complete genome of this bacterium.

Organism information

Classification and features

P. brassicacearum L13-6-12 is a motile, Gram-negative, non-sporulating rod in the order *Pseudomonadales* of the class *Gammaproteobacteria*. The rod-shaped cells are approximately 0.4 μ m in width and 0.8–1.5 μ m in length (Fig. 1 left). The strain is moderately fast-growing, forming 1 mm colonies within 1–2 days at 25 °C. Colonies formed on NBII agar plates are yellow shining, domed and moderately mucoid with smooth margins (Fig. 1 right). Cultivation for more than two weeks on NA result in a color change of the medium to dark brown. L13-6-12

²Institute of Environmental Biotechnology, Graz University of Technology, Petersgasse 12, 8010 Graz, Austria

was isolated from a potato rhizosphere from plants grown in a field trial in Groß Lüsewitz, Germany, in 1997 [1].

Even though the optimal growth temperature is 30 °C, L13-6-12 can also slowly replicate at 5 °C in liquid Luria Bertani medium. Growth was observed at 37 °C and slightly at 40 °C in this culturing medium as well as on solidified medium after 24 h. The strain grows in complex media, but not in Standard Succinate Medium (pH 7.0). Optimum pH for growth in LB is pH 7.0. The bacterium is an efficient colonizer of lettuce, potato [2, 3] and sugar beet plants, where microcolonies consisted of tens to hundreds of bacterial cells, forming an interconnected network between epidermal cells in the rhizoplane [3]. It does not cause any deleterious effect on its original host plant potato or lettuce [1, 2] and sugar beet [4] or on the nematode Caenorhabditis elegans [5]. Strain L13-6-12 has natural resistance to gentamycin (10 µg mL $^{-1}$), trimethoprim (50 µg mL $^{-1}$) and is able to develop spontaneous rifampicin-resistance.

Minimum Information about the Genome Sequence of *P. brassicacearum* L13-6-12 is summarized in Table 1. The phylogenetic relationship of *P. brassicacearum* L13-6-12 to other species within the genus *Pseudomonas* is visualized in a 16S rRNA based tree (Fig. 2) [6].

Genome sequencing information

Genome project history

Strain L13-6-12 was originally assigned to *P. fluorescens* based on 16S rRNA gene sequencing and alignments with NCBI database [1, 2, 4, 5]. After average nucleotide identity [7] comparison of the genome sequence against the genomes of the type strains and proxytype strains that are already in GenBank, L13-6-12 showed 99.604% identity to the type genome of *P. brassicacearum* with

95.5% coverage of the genome. The genome of *P. brassi-cacearum* strain L13-6-12 was selected for sequencing based on its ability to exert biocontrol abilities against fungal pathogens and to promote plant growth [1, 3]. This whole-genome shotgun project has been deposited in the NCBI database under the accession no. CP014693. The version described in this paper is the first version (Table 2).

Growth conditions and genomic DNA preparation

P. brassicacearum strain L13-6-12 was grown in 50 mL of NBII (Sifin, Berlin, Germany) medium and incubated for 20 h at 30 °C. 1.0 mL was centrifuged at 2500 × g for 5 min at 4 °C and genomic DNA was extracted using the MasterPure DNA purification kit (Epicentre, Madison, WI, USA). DNA quality and quantity were validated by agarose gel electrophoresis and spectrophotometry using a UV-Vis spectrophotometer (NanoDrop 2000c, Thermo Fisher Scientific, Waltham, MA USA). In total, 54 µg genomic DNA (1.8 µg µL⁻¹) was sent on dry ice to the sequencing service. PacBio RS libraries with inserts of 8 to 20 kb were constructed and sequenced at GATC Biotech (Konstanz, Germany).

Genome sequencing and assembly

PacBio RS libraries with inserts of 8 to 20 kb were constructed and sequenced at GATC Biotech (Konstanz, Germany) using single molecule, real-time sequencing. Assembly was completed with the Hierarchical Genome Assembly Process algorithm implemented in the PacBio SMRT Analysis software (Pacific Biosciences, Menlo Park, CA, USA). The assembly of L13-6-12 genome based on 130,283 quality reads with a mean length of 4995 bp resulting in a single circular chromosome consisting of

These evidence codes are from the Gene Ontology project [40]

6,715,909 bp, with 84.9-fold overall coverage and a GC content of 60.7%.

Genome annotation

Automatic annotation was conducted on the RAST Web server (version 36) using RAST gene calling based on FIGfam version Release70 [8, 9], and additional annotation for using the automated assignment of COGfunctions to protein-coding genes was completed on the BASys web server using Glimmer gene prediction [10, 11]. Pseudogenes were predicted using the NCBI Prokaryotic Genome Annotation Pipeline. Signal peptides and transmembrane helices were predicted using SignalP [12, 13] and TMHMM [14, 15].

Genome properties

The genome of L13-6-12 is composed of one circular chromosome consisting of 6,715,909 bp with an average

GC content of 60.7% (Table 3 and Fig. 3), which is similar to that of other *P. brassicacearum* strains. Among the 5887 predicted genes, 5773 were identified as protein coding genes. Of the last, 4801 (83.2%) were assigned a putative function, while the other 972 (16.8%) were designated as hypothetical proteins. The classification of CDSs into functional categories according to the COG [16, 17] database is summarized in Table 4 based on BASys gene prediction. Beside the predicted genes, the genome annotation contained 65 tRNA, five rRNA loci (5S, 16S, 23S) with one additional 5S rRNA, four ncRNAs and 284 predicted SEED subsystem features.

Insights from the genome sequence

The genome-wide phylogenetic analysis on different *Pseudomonas* species with the L13-6-12 genome showed that strain L13-6-12 clusters closely to *P. fluorescens* Q8r1-96 (NCBI Accession no. PRJNA67537) (Fig. 2).

Fig. 2 Phylogenetic tree showing the position of *P. brassicacearum* L13-6-12 in relationships among other strains of *Pseudomonas* spp. including *P. aeruginosa* PAO1 as outgroup. The tree is based on 16S rRNA gene alignments and was conducted in MEGA6 [41]. Initial tree for the heuristic search were obtained automatically by applying Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated using the Maximum Composite Likelihood approach, and then selecting the topology with superior log likelihood value

Recently, Q8r1-96 was described as a biological control strain that produces the antibiotic DAPG and that exceptionally colonizes the roots of wheat and pea [18, 19]. The genome of L13-6-12 contains several genes, which are important contributors to biological control. They are related to the biosynthesis of secondary metabolites or antimicrobial products that are similar to those found in the genomes of other Pseudomonads [20]. We detected genes for the biosynthesis of DAPG (Locus tags: A0U95_04640, A0U95_04655, A0U95_04660, A0U95_04665) and productions of exoproteases (A0U95_00125, A0U95_02755). The suppression of hyphal growth of S. rolfsii by volatile organic compounds produced by L13-6-12 was observed in a test system developed by Cernava et al. [21]. Volatile components have been shown to act as antibiotics and to induce plant growth [22, 23]. Hydrogen cyanide (HCN) is an inorganic volatile compound with antagonistic effects against soil microbes [24]. The production of HCN was observed in L13-6-12 (A0U95_28525) by applying an assay according

to Blom et al. [25]. Genes predicting biosynthesis of other volatile components such as 2,3-butanediol (A0U95_29290) and acetoin (A0U95_29285) were found as well.

We further identified genes most probably involved in the direct promotion of plant growth, such as biosynthesis or carrier gene clusters for spermidine (A0U95_07830), pyoverdine (e.g. A0U95_07605, A0U95_25745, A0U95_25750) and aminocyclopropane-1-carboxylate (ACC) deaminase

(A0U95_06530). ACC deaminase is suggested to be a key in the modulation of ethylene levels in plants by bacteria [26].

For secretion of extracellular proteins in the surrounding environment genes putatively encoding general secretory pathway proteins (Gsp) belonging to the type two secretion systems were found in L13-6-12 (e.g. A0U95_29195, A0U95_29200, A0U95_29205). Type six secretion systems have evolved in Gram-negative bacteria enabling them to interact with their host and to adapt to various microenvironments and specialized functions [27, 28]. Genes encoding components of the type six secretion system were found in L13-6-12 (e.g. A0U95_16935, A0U95_28720, A0U95_28755) putatively for interaction with eukaryotic organisms.

Conclusions

In this report, we describe the complete genome sequence of Pseudomonas brassicacearum strain L13-6-12, a strain that was originally isolated from the rhizosphere of potato grown in Groß Lüsewitz, Germany and which was originally assigned as P. fluorescens. This strain was selected for sequencing based on its ability to protect plants from biotic stresses and to promote plant growth. It also has a collection of genes predicting volatile components and enzymes such as a protease, ACC deaminase and spermidine enabling L13-6-12 to protect and promote its host plant. Genes, encoding putative T2SS, T4SS and T6SS, allowing interactions with the host and the environment were detected, too. Further functional studies and comparative genomics with related isolates will provide insights into mechanisms useful for novel biotechnological processes for seed and root applications since the strain represent a promising candidate for improving of plant performance.
