We have explored the potential of proteomic profiling to contribute to the delineation of the range of expression and subcellular localization of aldehyde dehydrogenases (ALDHs) in lung adenocarcinoma. In-depth quantitative proteomics was applied to 40 lung adenocarcinoma cell lines resulting in the identification of the known members of the ALDH family. Substantial heterogeneity in the level and occurrence of ALDHs in total lysates and on the cell surface and in their release into the culture media was observed based on mass spectrometry counts. A distinct pattern of expression of ALDHs was observed in cells exhibiting epithelial features relative to cells exhibiting mesenchymal features. Strikingly elevated levels of ALDH1A1 were observed in two cell lines. We also report on the occurrence of an immune response to ALDH1A1 in lung cancer.

## 1. Introduction

Aldehyde dehydrogenases (ALDHs) constitute a large family of enzymes that catalyze the oxidation of endogenous and exogenous aldehydes to carboxylic acids. The different family members exhibit heterogeneous tissue distribution and have been localized predominantly in the cytosol and mitochondria. ALDHs have been investigated primarily based on their gene expression, their immunohistochemical localization and based on their activity. Cell sorting techniques have been utilized to enrich for cells expressing these enzymes based on activity. The relevance of ALDHs to cancer stems in part from the role they may play during carcinogenesis, their association with therapeutic resistance, and more recently from a distinct pattern of expression of ALDH1A1 and ALDH3A1 in cancer stem cells, which has been exploited as a means to define this cell population in tumors [1–3]. Several studies have pointed to evidence for epithelial to mesenchymal transitions in cancer stem cells, defined, in

part, based on their ALDH expression or activity [4, 5]. While ALDH1 and 3 dominate the cancer stem cell literature, other ALDHs have also been explored. High-level expression of ALDH1B1 was observed in colon cancer by immunohistochemistry [6]. Moderate to strong staining for ALDH4A1, ALDH5A1, and ALDH6A1 was observed in most cancer tissue in Protein Atlas (<http://www.proteinatlas.org/>). Strong expression of ALDH7A1 has been found in human prostate cancer cell lines, primary tumors, and matched bone metastases, with evidence of its functional involvement in the formation of bone metastases [7]. Comparative analysis of hepatocellular carcinoma tissue and adjacent nontumor tissue identified changes in ALDHs1-3 proteins in tumor tissue [8].

Several studies have explored the biological significance of ALDHs specifically in lung cancer and have provided supportive evidence for the association between ALDH activity and lung cancer stem cells [9]. Flow cytometric analysis of a panel of lung cancer cell lines and patient-derived

tumors revealed the occurrence of a subpopulation of cells with elevated ALDH activity in most non-small cell lung cancers, which correlated with ALDH1A1 expression [10]. Immunohistochemical staining of a large panel of primary tumors revealed a significant correlation between ALDH1A1 expression and poor prognosis in patients, including those with early stage disease [10]. Likewise, in another study, expression of ALDH1 was found to be positively correlated with the stage and grade of lung tumors and related to a poor prognosis for patients with early-stage lung cancer [11]. Expression analysis of sorted cells revealed elevated Notch pathway transcript expression in ALDH-positive cells. Suppression of the Notch pathway resulted in a significant decrease in ALDH-positive lung cancer cells with concordant reduction in tumor cell proliferation and clonogenicity [10]. Downregulation of ALDH isozymes affects cell growth, cell motility, and gene expression in lung cancer cells [12]. Other ALDHs have also been explored in lung cancer. ALDH3B1 is expressed in a tissue-specific manner and in a limited number of cell types. ALDH3B1 expression was found to be upregulated in a high percentage of human tumors, particularly lung tumors [13].

In general, most studies of ALDHs in lung cancer have focused on particular members of the family. In-depth proteomic profiling allows delineation of proteins expressed in tumor cells and in subcellular compartments. In this study we applied quantitative in-depth proteomic profiling to assess the occurrence of ALDHs in whole lysates of 40 lung adenocarcinoma cell lines and to examine their association with the cell surface and the extent of their release into culture media. ALDH1A1 was further explored as a tumor antigen that induces an autoantibody response in lung cancer.

## 2. Methods

**2.1. Lung Adenocarcinoma Cell Line Culture.** Cells were grown in DMEM media (Invitrogen) containing 0.1% of dialyzed fetal bovine serum (FBS) (Invitrogen) and  $^{13}\text{C}$ -lysine instead of regular lysine, for 7 passages (1 : 2) according to the standard SILAC protocol [14]. Incorporation of  $^{13}\text{C}$  Lys isotope exceeded 90% of the total protein lysine content. The same batch of cells was used for extracting cell surface proteins and for analysis of conditioned media and whole-cell lysate proteins. The secreted proteins were obtained directly from the cell conditioned media after 48 h of culture. Cells and debris were removed by centrifugation at  $5000 \times g$  and filtration through a  $0.22 \mu\text{M}$  filter. Total extracts of cells were obtained by sonication of  $\sim 2 \times 10^7$  cells in 1 mL of PBS containing the detergent octyl glucoside (OG) (1% w/v) and protease inhibitors (complete protease inhibitor cocktail, Roche Diagnostics, Germany) followed by centrifugation at  $20,000 \times g$ .

**2.2. Capture of Cell Surface Proteins.** To isolate cell surface proteins,  $\sim 2 \times 10^8$  cells were biotinylated in the culture plate after extensive PBS rinsing, with 10 mL of 0.25 mg/mL of Sulfo-NHS-SS-BIOTIN in PBS at room temperature (23–24°C) for 10 min. The residual biotinylation reagent

was quenched with 10 mM lysine. Protein extraction was performed in a solution containing NP 40 detergent 2% (v/v) with cell disruption by sonication followed by centrifugation at  $20,000 \times g$ . Biotinylated proteins were chromatographically isolated by affinity chromatography using 1 mL of UltraLink Immobilized NeutrAvidin (Pierce) according to manufacturers' instruction. Proteins bound to the column were recovered by reduction of the biotinylation reagent with 5 mL of a solution containing 65  $\mu\text{M}$  of DTT and 1% octyl glucoside (OG) detergent for 1 h at 37°C. Eluted proteins were subsequently alkylated with 200  $\mu\text{M}$  of iodoacetamide at room temperature.

**2.3. Fractionation of Cell Extracts.** Cell surface, conditioned media, and total extract were fractionated by reversed-phase chromatography, using, respectively 500  $\mu\text{g}$ , 1 mg, and 1 mg of total protein. All the cell extracts were reduced and alkylated with iodoacetamide prior to chromatography. Separation was performed in a POROS R1/10 column (Applied Biosystems— $4.6 \times 50 \text{ mm}$ ) at 2.7 mL/min using a linear gradient of 10 to 80% of organic solvent over 30-minute run. Solvent system used was aqueous solvent, 5% acetonitrile/95% water/0.1% of trifluoroacetic acid; organic solvent, 75% acetonitrile/15% isopropanol/10% water/0.095% trifluoroacetic acid. Fractions were collected at a rate of 3 fractions/minute.

**2.4. Protein Identification by LC-MS/MS.** Protein digestion and identification by LC-MS/MS was performed as described previously [15]. Briefly, each one of the reversed-phase fractions was individually digested in-solution digestion with trypsin (400 ng/fraction) and grouped into 24 to 27 pools for each cell line and each compartment (i.e., cell surface, conditioned media, and soluble whole-cell lysate) based on chromatographic features. Pools were individually analyzed by LC-MS/MS in a LTQ-Orbitrap mass spectrometer (Thermo-Finnigan) coupled to a nanoflow chromatography system (Eksigent) using a 25 cm column (PicoFrit 75  $\mu\text{M}$  ID, New Objectives, packed in-house with Magic C18 resin) over a 90-minute linear gradient. Acquired data was automatically processed by the Computational Proteomics Analysis System (CPAS) [16]. The tandem mass spectra were searched against version 3.57 of the human IPI database. A variable modification of 6.020129 mass units was added to lysine residues for database searching to account for incorporation of the heavy lysine isotope. We applied the tools PeptideProphet [17] and ProteinProphet [18] to estimate the significance of peptide and protein matches. Identifications with a PeptideProphet probability of greater than 0.2 were selected and submitted to ProteinProphet. The latter infers a minimal set of proteins that explain the peptide evidence, assigning a probability to each protein based on the combined peptide probabilities. The derived protein identifications were filtered at a <5% error rate based on the probability that the best match obtained would fall in the distribution of random database matches [19]. A spectral counting method [20] was used to estimate protein enrichment for each compartment.

FIGURE 1: Extent of peptide coverage of ALDH1A1 in cell line H522 in the TCE, media, and cell surface, across the ALDH1A1 protein sequence. Blue bar: dbSNP; red bar: N-acetyls erine; black bar: conflict, V->I at 162; tan bar: non-Cys-containing tryptic peptide; orange bar: Cys-containing tryptic peptide; light tan bar: N-linked non-Cys-containing tryptic peptide; light orange bar: N-linked Cys-containing peptide.

FIGURE 2: Differential expression of ALDH1A3, ALDH1B1, and ALDH18A1 between cell lines with epithelial and cell lines with mesenchymal features based on MS/MS counts. A Mann-Whitney test was performed using MS/MS counts of epithelial and mesenchymal cell lines. ALDH1A3 and ALDH1B1 have significantly higher expression from TCE in epithelial cells as compared to mesenchymal ones, with a  $P$  value of 0.007 and 0.030, respectively. ALDH18A1 has significant higher expression from the cell surface in epithelial as compared to mesenchymal with a  $P$  value of 0.042.

**2.5. Two-Dimensional Polyacrylamide Gel Electrophoresis (2D PAGE).** Proteins derived from the extracts of the cultured H522 lung adenocarcinoma cell line were separated into two dimensions as described previously [21]. Briefly, cultured NCI-H522 cells were lysed in solubilization buffer (8 M urea (Bio-Rad), 2% Nonidet P-40, 2% carrier ampholytes, pH 4–8 (Gallard/Schlesinger, Carle Place, NY), 2%  $\beta$ -mercaptoethanol, and 10 mM PMSF). 200  $\mu$ g of solubilized proteins were applied onto isoelectric focusing gels. Isoelectric focusing was performed using pH 4–8 carrier ampholytes at 700 V for 16 h, followed by 1000 V for an additional 2 h. The first-dimension gel was loaded onto the second-dimension gel, after equilibration in 125 mM Tris (pH 6.8), 10% glycerol, 2% SDS, 1% DTT, and bromophenol blue. For the second-dimension separation, a gradient of 11–14% acrylamide (Crescent Chemical, Hauppauge, NY) was used. The resolved proteins were transferred to an Immobilon-P polyvinylidene difluoride (PVDF) membrane (Millipore, Bedford, Mass). Protein patterns in some gels were visualized directly by silver staining or Sypro Ruby staining.

**2.6. Western Blotting and Image Analysis.** After transfer, membranes were incubated with a blocking buffer consisting of PBS and 0.1% Tween-20 containing 1.8% nonfat dry milk for 2 h. The membranes were incubated for 1 h at room temperature with serum obtained from either patients or control individuals as a source of primary antibody at a 1:100 dilution. Some additional membranes were incubated with an antibody to ALDH1A1 to visualize the protein. After three washes with washing buffer (PBS containing 0.1% Tween 20), the membranes were incubated with horseradish peroxidase-conjugated sheep anti-human IgG (Amersham Biosciences, Piscataway, NJ) at a dilution of 1:1000 for 1 h at room temp. Immunodetection was accomplished by enhanced chemiluminescence (Amersham Biosciences) followed by exposure on Hyperfilm MP (Amersham Biosciences). Films were digitized with a Kodak CCD camera. The spots on each image were detected and quantified as previously described [21]. After immunoblotting, all membranes were Coomassie Blue stained, and the patterns obtained were compared to those of the films in order to determine the locations of reactive spots. Spot integrated intensities were normalized

FIGURE 3: Extent of peptide coverage of ALDH1A3 across cell lines based on spectral counts from MS data.

by dividing by the intensity of a reference HSP27 protein spot. HRP-conjugated goat anti-mouse secondary antibody was spiked into the sheep anti-human cocktail at a 1 : 1000 dilution to facilitate detection.

**2.7. Statistical Analysis.** The data was analyzed using one-sided Rank-Sum tests.

### 3. Results

**3.1. Occurrence of ALDHs among Lung Adenocarcinoma Cell Lines and in Subcompartments.** Comprehensive proteomic profiling of 40 lung cancer cell lines resulted in the identification of known members of the ALDHs family in one or more cell lines. There was substantial heterogeneity in the abundance of individual family members among cell lines and in their occurrence and distribution between whole-cell lysates, on the cell surface and their release into the media of cultured cells (Table 1). ALDH1A1, ALDH1A3, ALDH2, ALDH3A1, ALDH7A1, and ALDH9A1 had more than 1,000 total MS counts each in total cell extracts across cell lines. ALDH1A1 and ALDH3A1 exhibited discordant expression with an overall total of MS counts for ALDH1A1 exceeding that of ALDH3A1 (Table 1), with some cell lines yielding high MS counts for ALDH1A1 with low counts or undetectable for ALDH3A1. The highest MS counts were observed for ALDH2 and ALDH1A1. However, whereas ALDH2 was relatively uniformly distributed across cell lines, expression of ALDH1A1 was more limited to just a few cell

lines. Notably, cell line H522 yielded extremely high MS counts for ALDH1A1 relative to most other cell lines, and relative to other ALDHs (Table 2). Several ALDH proteins for which we provide evidence of expression in lung cancer cell lines (Table 1) were previously not characterized in lung cancer. ALDH9A1 was identified in most cell lines and was among the most abundant ALDH proteins identified based on spectral counts.

#### 3.2. Occurrence of ALDHs in the Extracellular Compartment.

We sought to determine the occurrence of ALDHs on the cell surface and their release into culture media. Whereas all ALDH proteins were identified in total cell extracts (TCE), for most proteins a significant fraction was observed in both the cell surface fraction (Surf) and the media (Med) (Table 1). For example, ALDH1A1 in H522 was predominant in both the TCE and Med (Table 2) whereas other proteins (e.g., ALDH3A2 and ALDH5A1) displayed a substantial proportion of protein abundance on the cell surface (Table 1). We examined whether MS data was suggestive of the occurrence of cleavage forms of ALDHs in the media or on the cell surface. However, the data obtained pertaining to peptide representation of the proteins was not suggestive of cleavage, or alternatively spliced forms of proteins associated with the cell surface or, for that matter, with their release into the media as exemplified for ALDH1A1 in H522 (Figure 1).

#### 3.3. Differential Expression of ALDHs Based on Epithelial/Mesenchymal Features.

Twenty-five of the 40 cell lines

investigated could be classified as either epithelial or mesenchymal based on their morphology and their expression of vimentin and E-cadherin. ALDH protein expression was examined in relation to cell line epithelial/mesenchymal characteristics. ALDH1A3, ALDH1B1, and ALDH18A1 exhibited statistically significant differences in their MS counts in epithelial versus mesenchymal cell lines (Table 3, Figure 2). Whereas the stem cell markers ALDH1A1 and ALDH3A1, did not yield statistically significant differences between epithelial and mesenchymal cell lines, a very high number of MS spectral counts were observed for ALDH1A1 in the two mesenchymal cell lines H522 and H1703 (Table 3). The extent of peptide coverage for ALDH1A3, ALDH1B1, and ALDH18A1 between epithelial and mesenchymal cell lines appears to be related to the total number of MS

counts rather than to epithelial/mesenchymal characteristics, as shown in Figure 3 for ALDH1A3 in TCE.

*3.4. Lung Cancer Sera Exhibit IgG-Based Reactivity to ALDH1A1.* H522 tumor cell line proteins were separated by 2D PAGE and transferred onto Immobilon-P PVDF membranes, and the membranes were used to screen individual lung cancer and control sera for autoantibodies directed against H522 proteins. Sera from 25 lung cancer patients (9 adenocarcinomas, 6 small cell, and 10 squamous lung cancers) and 25 age- and sex-matched healthy controls were investigated. Two neighboring spots, both with similar apparent molecular weight (approximately 55 kDa) but slightly different isoelectric points (6.6 and 6.45, resp.), were observed to exhibit frequent reactivity in lung cancer patients

(Figure 4). The data for the more acidic spot was highly correlated to the more basic spot values, giving a Spearman's rank correlation of 0.62 with a  $P$  value of  $2.3 \times 10^{-6}$ . The more basic spot was excised from gels on two occasions and digested with trypsin, with the resulting tryptic digests subjected to mass spectrometric analysis. We obtained 46 and 45 spectra matching the aldehyde dehydrogenase 1A1 protein

(NP\_000680, gene symbol ALDH1A1) on the two runs. These matches amounted to 26 and 22 distinct peptides, with MASCOT search engine scores of 1503 and 1464, respectively. The more acidic spot was also identified as ALDH1A1, with 21 matching peptides and MASCOT score of 1329.

Spot integrated intensities on the films were measured and analyzed by one-sided Rank-Sum tests. We obtained

FIGURE 4: Occurrence of autoantibodies to ALDH1A1 in lung cancer. A rectangle marks the location of ALDH1A1 in a silver-stained 2D gel of H522 lysate, also shown in a close-up below (A). The acidic and basic ALDH1A1 reactive spots in Western blots hybridized with subject sera (B and C) are indicated with arrows.

estimated  $P$  values of 0.0018 (basic) and 0.0026 (acidic) from 10000 permuted data sets, indicating greater reactivity in lung cancer patients compared to healthy controls. Two receiver operating characteristic (ROC) curves were constructed, each using the data for a single protein spot (either the more basic or more acidic spot). For the more basic spot, an AUC of 0.69 was obtained. An AUC of 0.68 was obtained for the more acidic spot.

#### 4. Discussion

Comprehensive proteomic profiling delineated the range of expression and localization of ALDHs in total cell lysates, the cell surface, and their release into the media of cultured lung adenocarcinoma cell lines. A striking finding is the extent to which ALDHs localize to the cell surface and/or are released into the media. The evidence obtained based on the peptides identified for various ALDHs does not suggest the occurrence of distinct forms of ALDHs in different compartments, thus the mechanisms involved and the role of ALDHs localized to the cell surface or release into the media largely remain to be determined.

We observed a distinct pattern of expression of ALDHs in cell lines exhibiting epithelial versus mesenchymal features. In other studies, ALDH expression was found to mark pancreatic cancer cells that have stem cell and mesenchymal features [22]. ALDH expression was analyzed by immunohistochemistry in 269 primary surgical specimens of pancreatic adenocarcinoma and examined for association with clinical outcomes and in paired primary tumors and metastatic lesions from eight pancreatic cancer patients who had participated in a rapid autopsy program. The clonogenic growth

potential of ALDH-positive pancreatic adenocarcinoma cells was assessed in vitro by a colony formation assay and by tumor growth in immunodeficient mice. ALDH-positive tumor cells were detected in 90 of the 269 primary surgical specimens, and their presence was associated with worse survival. Six of the eight patients with matched primary and metastatic tumor samples had ALDH-negative primary tumors, and in four of these six patients, the matched metastatic lesions contained ALDH-positive cells which expressed genes consistent with a mesenchymal state [22].

The extent to which mesenchymal features correlate with a stem cell phenotype reflected in a common ALDH expression pattern remains to be determined. In our studies, ALDH1A1 and ALDH3A1, which have been associated with stem cell features, exhibited distinct expression patterns among the cell lines analyzed. ALDH3A1 did not yield a significant association with a mesenchymal phenotype whereas ALDH1A1 exhibited strikingly high expression based on MS counts in two cell lines with a mesenchymal phenotype. Moreover, ALDH1A3, ALDH1B1, and ALDH18A1 exhibited a statistically significant difference in their protein expression between cell lines with epithelial and mesenchymal features.

We utilized lysates from H522, a lung adenocarcinoma cell line that expresses high levels of ALDH1A1 to characterize the humoral immune response in lung cancer. We obtained evidence for autoreactivity against two forms of ALDH1A in sera from subjects with lung cancer relative to healthy controls. The reactivity observed was not limited to lung adenocarcinoma, as sera from subjects with squamous cell lung cancer and small cell lung cancer exhibited similar reactivity. An immune response to ALDH1A1 has been reported in other studies. ALDH1A1 was identified as a novel CD8+ T-cell-defined tumor antigen in squamous cell carcinoma of the head and neck [23]. Mass spectral analysis of peptides in tumor-derived lysates was used to determine that the CTL line recognized the HLA-A2 binding ALDH1A1 (88–96) peptide. ALDH1A1(88–96) peptide-specific CD8(+) T cells recognized only HLA-A2(+) cell lines which over expressed ALDH1A1 and cells transfected with ALDH1A1 cDNA. In another study, sera from three of five patients with lung adenocarcinoma and none of ten controls with lung tuberculosis were found to exhibit IgG-based seroreactivity against aldehyde dehydrogenase identified in A549 lung adenocarcinoma cell line lysate using an approach similar to the approach for IgG reactivity against ALDH1A1 utilized in this study [24].
