

CONJUGACY LANGUAGES IN GROUPS

LAURA CIOBANU, SUSAN HERMILLER, DEREK HOLT, AND SARAH REES

ABSTRACT. We study the regularity of several languages derived from conjugacy classes in a finitely generated group G for a variety of examples including word hyperbolic, virtually abelian, Artin, and Garside groups. We also determine the rationality of the growth series of the shortlex conjugacy language in virtually cyclic groups, proving one direction of a conjecture of Rivin.

2010 Mathematics Subject Classification: 20F65, 20E45; 20F67, 20F36.

Key words: Conjugacy growth, regular languages, word hyperbolic groups, Artin groups, Garside groups.

1. INTRODUCTION

Many classes of finitely presented groups have been studied via the formal language theoretic properties of their sets of geodesics or shortlex least representatives of the group elements. In this paper we study the regularity of three languages derived from the conjugacy classes, rather than elements, of some of these groups.

A regular language is recognized by a finite state automaton, and one particularly useful application is the existence of an algorithm that uses this automaton to calculate a rational function equal to the growth series (that is, the generating function associated to the growth function) of the language.

Before proceeding further, we need to recall some notation. We use standard notation from formal language theory and refer to [19] for details. Where X is a finite set, we denote by X^* the set of all words over X , and call a subset of X^* a language. We write ε for the empty word, and denote by X^+ the set of all non-empty words over X (so $X^* = X^+ \cup \{\varepsilon\}$). For each word $w \in X^*$, let $l(w) = l_X(w)$ denote its length over X . For subsets A, B of X^* , we define AB to be the set of concatenations wu with $w \in A, u \in B$. Similarly we define A^n to be the set of concatenations of n words from A , $A^* = \cup_{n=0}^{\infty} A^n$, $A^+ = \cup_{n=1}^{\infty} A^n$. A language is regular if it can be built out of finite subsets of X using the operations of union, concatenation, $*$ (and complementation); such an expression for a language is called a *regular expression*.

All groups we consider in this paper are finitely generated, and all generating sets finite and inverse-closed. Let $G = \langle X \rangle$ be a group. Let $\pi : X^* \rightarrow G$ be the natural projection onto G , and let $=$ denote equality between words and $=_G$ equality between group elements (so $w =_G v$ means $\pi(w) = \pi(v)$). For $g \in G$, define the

length of g , denoted $|g|$ ($= |g|_X$), to be the length of a shortest representative word for g over X . Define a *geodesic* to be a word $w \in X^*$ with $l(w) = |\pi(w)|$.

Let \sim denote the equivalence relation on G given by conjugacy, and G/\sim its set of equivalence classes. Let $[g]_c$ denote the conjugacy class of $g \in G$. Define the *length up to conjugacy* of an element g of G , denoted $|g|_c$, by

$$|g|_c := \min\{|h| \mid h \in [g]_c\}.$$

We say that g has *minimal length up to conjugacy* if $|g| = |g|_c$.

We call a word $w \in X^*$ satisfying $l(w) = |\pi(w)|_c$ a *geodesic with respect to conjugacy*, or a *conjugacy geodesic* word. Note that if a word w is a conjugacy geodesic, then so is every cyclic permutation of w . By contrast, a word $w \in X^*$ satisfying the property that every cyclic permutation is a geodesic is not necessarily a conjugacy geodesic. Call a word whose cyclic permutations are all geodesics a *geodesic with respect to cyclic permutation*, or a *cyclic geodesic* word.

We consider six languages associated to the pair (G, X) , the first three being:

$$\begin{aligned} \text{Geo} = \text{Geo}(G, X) &:= \{w \in X^* \mid l(w) = |\pi(w)|\}, \\ \text{ConjGeo} = \text{ConjGeo}(G, X) &:= \{w \in X^* \mid l(w) = |\pi(w)|_c\}, \\ \text{CycGeo} = \text{CycGeo}(G, X) &:= \{w \in X^* \mid w \text{ is a cyclic geodesic}\}, \end{aligned}$$

which we call the *geodesic language*, *conjugacy geodesic language*, and *cyclic geodesic language*, respectively, of G with respect to X . The conjugacy geodesic language was introduced by the first two authors in [7], where it is shown that the property of having both Geo and ConjGeo regular is preserved by taking graph products.

Although Geo and ConjGeo capture much of the geometric information about the elements and conjugacy classes of G , it is desirable also to have languages whose growth functions are exactly the growth functions of the elements, minimal length elements up to conjugacy, and conjugacy classes of G , respectively. To that end, let \leq be a total ordering of X , and let \leq_{sl} be the induced shortlex ordering of X^* (for which $u <_{sl} w$ if either $l(u) < l(w)$, or $l(u) = l(w)$ but u precedes w lexicographically).

For each $g \in G$, we define the *shortlex normal form* of g to be the unique word $y_g \in X^*$ with $\pi(y_g) = g$ such that $y_g \leq_{sl} w$ for all $w \in X^*$ with $\pi(w) = g$. For each conjugacy class $c \in G/\sim$, we define the *shortlex conjugacy normal form* of c to be the shortlex least word z_c over X representing an element of c ; that is, $\pi(z_c) \in c$, and $z_c \leq_{sl} w$ for all $w \in X^*$ with $\pi(w) \in c$.

Our remaining three languages are the *shortlex language*, *shortlex minimal conjugacy language*, and *shortlex conjugacy language* for G over X , defined respectively as

$$\begin{aligned} \text{SL} = \text{SL}(G, X) &:= \{y_g \mid g \in G\}, \\ \text{ConjMinLenSL} = \text{ConjMinLenSL}(G, X) &:= \{y_g \mid |g| = |g|_c\}, \text{ and} \\ \text{ConjSL} = \text{ConjSL}(G, X) &:= \{z_c \mid c \in G/\sim\}. \end{aligned}$$

We note that the language ConjMinLenSL of shortlex normal forms for the set ConjMinLen of minimal length elements up to conjugacy in G satisfies $\text{ConjMinLenSL} = \text{ConjGeo} \cap \text{SL}$.

Our six languages satisfy the following containments.

$$\begin{array}{ccccc} \text{ConjGeo} & \subseteq & \text{CycGeo} & \subseteq & \text{Geo} \\ \cup & & & & \cup \\ \text{ConjSL} \subseteq \text{ConjMinLenSL} & & \subseteq & & \text{SL} \end{array}$$

Any language L over X gives rise to a *strict growth function* $\phi_L : \mathbb{N} \cup \{0\} \rightarrow \mathbb{N} \cup \{0\}$, defined by $\phi_L(n) := |\{w \in L \mid l(w) = n\}|$, and an associated generating function, called the *strict growth series*, given by $f_L(z) := \sum_{i=0}^{\infty} \phi_L(i)z^i$. It is well known that if L is a regular language, then f_L is a rational function. For the three languages above, the coefficient $\phi_{\text{SL}}(n)$ is the number of elements of G of length n , $\phi_{\text{ConjMinLenSL}}(n)$ is the number of minimal length elements of G up to conjugacy of length n , and $\phi_{\text{ConjSL}}(n)$ is the number of conjugacy classes of G whose shortest elements have length n . Note that all three of these numbers depend only on G, X and not on our choice of SL as a language of geodesic normal forms for G ; the growth series $f_{\text{SL}}, f_{\text{ConjMinLenSL}}$, and f_{ConjSL} would be the same with respect to any geodesic normal form. We consider the last of these series in two examples in this paper. To emphasize this independence from the shortlex ordering, we denote by $\tilde{\sigma}$ the strict growth series of ConjSL , that is,

$$\tilde{\sigma} = \tilde{\sigma}(G, X) := f_{\text{ConjSL}(G, X)}(z) = \sum_{i=0}^{\infty} \phi_{\text{ConjSL}(G, X)}(i)z^i,$$

following the notation of [7], and call that series the *spherical conjugacy growth series*.

In Section 2, Proposition 2.2 proves that regularity of Geo implies the same for CycGeo . Theorem 2.4 proves that equality of the languages CycGeo and ConjGeo is preserved by taking graph products, giving Corollary 2.5 that ConjGeo and CycGeo are equal (over the standard generating set) for all right-angled Artin and right-angled Coxeter groups.

Section 3 studies regularity of the conjugacy languages for many families known to have regular geodesic languages. These include word hyperbolic groups (for all generating sets) [9, Theorem 3.4.5] and, with appropriate generating sets, virtually abelian groups and geometrically finite hyperbolic groups [24, Theorem 4.3], Coxeter groups [18], right-angled Artin groups [21], Artin groups of large type [16], and Garside groups (and hence Artin groups of finite type and torus knot groups) [6]. For groups in most of these families, we have succeeded in proving the regularity of ConjGeo and ConjMinLenSL . Moreover, for virtually abelian groups, we build on [12, Prop. 6.3] to exhibit a generating set for which ConjGeo has the stronger property of piecewise testability (see Definition 3.2).

We summarize the results known for these families of groups in Table 1, where the symbol * means that the property holds for all generating sets, and if * does not appear, the result is only known to hold for a specific generating set.

In the cases of virtually abelian groups and Garside groups, we found no proofs in the literature of their shortlex automaticity with respect to the generating sets under consideration, and so we have also supplied those in Section 3.

TABLE 1. Summary of language properties for groups in Sections 3 & 4

Note that Table 1 includes many families of Artin groups, including those of spherical (i.e. finite) type (which are homogeneous Garside groups), and also right-angled Artin and Coxeter groups, as graph products of appropriate vertex groups. (The graph product results are included in the table for completeness, but are all proved elsewhere.)

For two of the blank entries in Table 1 in the ConjSL column, namely word hyperbolic and graph product groups, we note that there are examples of groups and finite generating sets for which ConjSL is not regular for any total ordering of the generators. In particular, Rivin [27],[26] and Ciobanu and Hermiller [7] have shown that for a free product of two infinite cyclic groups or two finite cyclic groups of order greater than 2, with respect to the cyclic generators (in the infinite case) or the nontrivial elements of the finite cyclic factors, respectively, the spherical conjugacy growth series is not rational.

Some of the results in Section 3 have consequences for groups beyond those treated in this paper. In [1, Section 8] Antolín and the first author have shown that certain relatively hyperbolic groups have regular ConjGeo by using Corollary 3.8.

Section 4 is devoted to a conjecture of Rivin [27],[26] about the rationality of the spherical conjugacy growth series $\tilde{\sigma}$ for word hyperbolic groups. In Theorem 4.2 we verify one direction of the conjecture, proving that for a virtually cyclic group ConjSL is regular, and hence that $\tilde{\sigma}$ is rational. This result is included in Table 1.

Section 5 examines two virtually abelian groups to demonstrate how regularity properties can differ between the various languages we consider, and depend on

choice of generating set. Cannon [24, p. 268] showed that regularity of Geo depends upon the generating set for $G = \mathbb{Z}^2 \rtimes \mathbb{Z}/2\mathbb{Z}$. Using the same two generating sets as Cannon, we show in Propositions 5.1 and 5.2 that regularity of ConjSL can depend upon the generating set. At the same time, we prove for one of these generating sets that, although $\text{ConjSL}(G, Z)$ is not regular (with respect to any total ordering of Z), $\tilde{\sigma}(G, Z)$ is rational. Moreover, over the generating set used in Proposition 5.2, we show that $\text{ConjGeo}(G, X)$ is regular but $\text{Geo}(G, X)$ is not, and similarly ConjMinLenSL and ConjSL are regular but SL is not. Considering a further finite extension $K = \mathbb{Z}^2 \rtimes D_8$ of G in Propositions 5.3 and 5.4, we show that regularity of the conjugacy geodesic language and shortlex minimal conjugacy language can also depend upon the generating set. These results are summarized in Table 2.

TABLE 2. Summary of language properties for groups in Section 5

The languages studied in this paper merit exploration not just because of the role they play in determining the conjugacy growth of a group, but also for their potential connections to the computational complexity of the conjugacy problem. We observe that a recursively presented group $G = \langle X \mid R \rangle$ for which $\text{ConjSL}(G, X)$ is recursive has solvable conjugacy problem. (Given $u \in X^*$, we find the shortlex representative of $[u]_c$ by simultaneously enumerating conjugates $y^{-1}uy$ of u , words $w \in \text{ConjSL}(G, X)$ with $l(w) \leq l(u)$, and products z of conjugates of relators, and computing the free reduction of each $y^{-1}uyw^{-1}z$. When that is the empty word, w is the shortlex representative of $[u]_c$.) However Chuck Miller has pointed out to us that the example of an amalgamated product T of two free groups of the same rank described in [23, Section IVA] has unsolvable conjugacy problem but has recursive ConjGeo . Another open question of interest is what regularity of ConjSL or ConjGeo implies for the computational complexity of this important decision problem.

2. CONJUGACY VERSUS CYCLIC GEODESICS

For any language $L \subset X^*$, let $\text{Cyc}(L)$ denote the *cyclic closure* of L ; that is, $\text{Cyc}(L)$ is the set of all cyclic permutations of words in L .

Lemma 2.1. *If a language L is regular, then $\text{Cyc}(L)$ is also regular.*

Proof. Let M be a finite state automaton accepting L , with state set Q and initial state q_0 . A word w lies in $\text{Cyc}(L)$ if and only if, for some factorisation w_1w_2 of w ,

and for states $q, q' \in Q$, with q' accepting, M contains both a path from q to q' labelled by w_1 and a path in M from q_0 to q labeled by w_2 . From this description we construct a set of non-deterministic automata M_q , indexed by the states of Q , the union of whose languages is $\text{Cyc}(L)$.

The automaton M_q is formed from two disjoint copies $M_{q,1}$ and $M_{q,2}$ of the states and transitions of M . The initial state of M_q is the state q in $M_{q,1}$ and the single accept state is the state q in $M_{q,2}$. Additional ϵ -transitions join each state of $M_{q,1}$ that is accepting in M to the state q_0 in $M_{q,2}$. \square

Proposition 2.2. *For $G = \langle X \rangle$, if $\text{Geo}(G, X)$ is regular then so is $\text{CycGeo}(G, X)$.*

Proof. This follows directly from Lemma 2.1 and the fact that cyclic geodesics are the words that are not cyclic conjugates of nongeodesics; that is,

$$\text{CycGeo} = X^* \setminus \text{Cyc}(X^* \setminus \text{Geo}).$$

\square

The following is an immediate consequence of the above proposition.

Proposition 2.3. *For $G = \langle X \rangle$, if $\text{Geo}(G, X)$ is regular and $\text{CycGeo}(G, X) = \text{ConjGeo}(G, X)$, then $\text{ConjGeo}(G, X)$ is also regular.*

Given a finite simplicial graph Λ with vertices labeled by groups G_i , the associated graph product group G is generated by the groups G_i , with the added relations that whenever the vertices labeled G_i and G_j are adjacent, then the elements of G_i and G_j commute.

Theorem 2.4. *Suppose that $G_i = \langle X_i \rangle$, with $\text{CycGeo}(G_i, X_i) = \text{ConjGeo}(G_i, X_i)$, for each i . If G is a graph product of these groups with generating set $X = \cup_i X_i$, then $\text{CycGeo}(G, X) = \text{ConjGeo}(G, X)$.*

Proof. The containment $\text{CycGeo}(G, X) \supseteq \text{ConjGeo}(G, X)$ is immediate from the definitions.

For each index i , let $\text{Geo}_i := \text{Geo}(G_i, X_i)$, and let $\$$ be a symbol not in X_i . Define the map $\rho_i : X^* \rightarrow (X_i \cup \$)^*$ by, for $a \in X_j$, setting $\rho_i(a) := a$ if $i = j$, $\rho_i(a) := \epsilon$ (the empty word) if the vertices i and j are adjacent in the defining graph Λ of the graph product, and finally $\rho_i(a) := \$$ if the vertices i and j are neither equal nor adjacent. In [7, Props. 3.3, 3.5], the first two authors show that, for $w \in X^*$,

$$w \in \text{ConjGeo}(G, X) \iff \forall i,$$

$$\rho_i(w) \in \text{ConjGeo}(G_i, X_i) \cup \{u_0 \$ u_1 \cdots \$ u_n \mid n \geq 1 \text{ and } u_n u_0, u_1, \dots, u_{n-1} \in \text{Geo}_i\};$$

moreover, w is geodesic if and only if $\rho_i(w) \in \text{Geo}_i(\$ \text{Geo}_i)^*$ for all i .

Suppose now that $w \in \text{CycGeo}(G, X)$. For each index i , we have $\rho_i(w) = u_0 \$ u_1 \cdots \$ u_n$ with $n \geq 0$ and each $u_j \in \text{Geo}_i$. Note that whenever w' is a cyclic permutation of w , then $\rho_i(w')$ is a cyclic permutation of $\rho_i(w)$. In particular there is a cyclic permutation w' of w such that $\rho_i(w') = u_n u_0 \$ u_1 \cdots u_{n-1} \$$. Now since $w' \in \text{Geo}(G, X)$ as well, we have $u_n u_0, u_1, \dots, u_{n-1} \in \text{Geo}_i$. Suppose further that

$n = 0$, that is, $\rho_i(w) = u_0 \in \text{Geo}_i$. Now for every cyclic permutation u' of u_0 , there is a cyclic permutation w' of w such that $\rho_i(w') = u'$, and hence we must have $u' \in \text{Geo}_i$. Thus in this case $u_0 \in \text{CycGeo}(G_i, X_i)$, and so by hypothesis also $u_0 \in \text{ConjGeo}(G_i, X_i)$. Therefore $w \in \text{ConjGeo}(G, X)$, as required. \square

In [7] the first two authors show that whenever the languages $\text{Geo}, \text{ConjGeo}$ are both regular for all vertex groups, then both are regular for the graph product group. Theorem 2.4, however, gives a slightly stronger result about the structure of the geodesics involved, which we highlight in the case of right-angled Artin and Coxeter groups.

Corollary 2.5. *For every right-angled Artin group (respectively, every right-angled Coxeter group) G with respect to the Artin (respectively, Coxeter) generators X , a word w is a conjugacy geodesic if and only if every cyclic conjugate of w is geodesic; that is, $\text{ConjGeo}(G, X) = \text{CycGeo}(G, X)$.*

3. RESULTS ABOUT GROUPS WITH REGULAR GEODESIC LANGUAGES

In this section we study conjugacy languages associated to particular families of groups, including word hyperbolic, virtually abelian, locally testable, (extra) large type Artin, and Garside groups, for which the geodesic language is regular. In each of these cases, we prove that the conjugacy geodesic language ConjGeo is also regular.

3.1. Word hyperbolic groups. For a word hyperbolic group G , regularity of the geodesic and shortlex languages holds for every finite generating set [9, Thms. 3.4.5, 2.5.1]. In the following we show that the same is true for the conjugacy geodesic language.

Theorem 3.1. *Let $G = \langle X \rangle$ be a word hyperbolic group. Then $\text{ConjGeo}(G, X)$ and $\text{ConjMinLenSL}(G, X)$ are regular.*

Proof. Since $\text{ConjMinLenSL}(G, X) = \text{ConjGeo}(G, X) \cap \text{SL}(G, X)$, and SL is regular, it suffices to prove the result for ConjGeo . We suppose that G has hyperbolicity constant $\delta \geq 0$ (i.e. geodesic triangles in the Cayley graph are δ -slim). By [4, Lemma III.2.9], two words $u, v \in \text{CycGeo}(G, X)$ with $\max\{l(u), l(v)\} \geq 8\delta + 1$ represent conjugate elements precisely when there exist $u' \in \text{Cyc}(\{u\}), v' \in \text{Cyc}(\{v\})$ representing elements conjugate by a word of length at most $2\delta + 1$. From this we deduce that a word $v \in \text{CycGeo}$ of length at least $8\delta + 1$ is outside ConjGeo precisely when it is in the cyclic closure of the set $\bigcup_{|\alpha| \leq 2\delta + 1} L(\alpha)$ where, for $\alpha \in X^*$,

$$L(\alpha) := \{v' \in \text{CycGeo} \mid \exists u' \in \text{CycGeo} \text{ such that } \alpha^{-1}u'\alpha =_G v', l(v') > l(u')\}.$$

Since the set $\text{ConjGeo} \cap (\bigcup_{k=0}^{8\delta+1} X^k)$ is finite, it is sufficient to prove the regularity of the set

$$\text{Cyc} \left(\bigcup_{|\alpha| \leq 2\delta + 1} L(\alpha) \right).$$

Since the family of regular sets is closed under both finite union and cyclic closure (Proposition 2.1), it is enough to show the regularity of $L(\alpha)$, for a given word α .

Now, since G is hyperbolic it has a biautomatic structure on Geo . By [11, Lemma 8.1], for any word α , the language

$$L_1(\alpha) := \{(u, v) \mid u, v \in \text{Geo}(G, X), v =_G \alpha^{-1}u\alpha\}$$

is regular.

By Proposition 2.2, $\text{CycGeo}(G, X)$ is regular and by standard arguments so are the languages

$$\begin{aligned} L_2 &:= \{(u, v) \mid u, v \in \text{CycGeo}(G, X), l(v) > l(u)\}, \\ L_3(\alpha) &:= L_1(\alpha) \cap L_2, \quad \text{and} \\ L_4(\alpha) &:= \{v \in \text{CycGeo} \mid \exists u \in \text{CycGeo}, (u, v) \in L_3(\alpha)\}. \end{aligned}$$

We see that $L_4(\alpha) = L(\alpha)$. □

In contrast, for the shortlex conjugacy language, Rivin [27], [26] and Ciobanu and Hermiller [7] have given examples of word hyperbolic groups and specific generating sets for which the spherical conjugacy growth series is not rational, and so ConjSL is not regular for any total ordering of the generators. More precisely, $\tilde{\sigma}$ was proved non-rational for free products of the form $\mathbb{Z} * \mathbb{Z}$ and $\mathbb{Z}/m\mathbb{Z} * \mathbb{Z}/n\mathbb{Z}$ with $m, n > 2$, using as generators in the first case cyclic generators for the two copies of \mathbb{Z} and in the second case all nontrivial elements of the two finite cyclic groups.

3.2. Virtually abelian groups. In [24, Props. 4.1, 4.4] Neumann and Shapiro show that for every virtually abelian group, there is a generating set for the group such that the corresponding set of geodesic words is regular, and in [12, Prop. 6.3], Hermiller, Holt, and Rees strengthen this result by showing that the geodesic words are a piecewise testable language. In the following we adjust that proof to show that for some choice of generators the language of conjugacy geodesics is also piecewise testable.

Definition 3.2. Let A be a finite alphabet.

(1) A subset L of A^* is called *piecewise testable* if it is defined by a regular expression that combines terms of the form $A^*a_1A^*a_2 \dots A^*a_kA^*$ using the Boolean operations of union, intersection and complementation, where $k \geq 0$ and each $a_i \in A$.

(2) A subset L of A^* is called *piecewise excluding* if there is a finite set of strings $W \subset A^*$ with the property that a word $w \in A^*$ lies in L if and only if w does not contain any of the strings in W as a not necessarily consecutive substring. In other words,

$$L = (\cup_{i=1}^n \{A^*a_{i_1}A^*a_{i_2}A^* \dots A^*a_{i_i}A^*\})^c,$$

where $W = \{a_1, \dots, a_n\}$ and $a_i = a_{i_1}a_{i_2} \dots a_{i_i}$ for $1 \leq i \leq n$.

According to Definition 3.2, piecewise excluding languages are also piecewise testable.

Proposition 3.3. *Let G be a virtually abelian group. There exists a finite generating set Z for G such that $\text{ConjGeo}(G, Z)$ is piecewise testable. Furthermore, there is an ordering of Z with respect to which G is shortlex automatic and $\text{ConjMinLenSL}(G, Z)$ is regular.*

Proof. This argument follows closely the proof of [12, Prop. 6.3], so we omit some of the details.

Let G be a virtually abelian group, and let $N \triangleleft G$ be abelian of finite index in G with a finite generating set A . Let $T \cup \{1\}$ be a transversal of N in G .

We build the generating set Z for G as follows. Let $Y := T^{\pm 1}$. Let X' be the set of all $x \in N$ such that $x =_G w \neq_G 1$ for some $w \in Y^*$ with $l(w) \leq 4$. Finally, let X be the closure of the set $A \cup X'$ in G under inversion and conjugation, and let $Z := X \cup Y$. Then

- (i) $X \subset N, Y \subset G \setminus N$,
- (ii) both X and Y are closed under inversion,
- (iii) X is closed under conjugation by elements of G ,
- (iv) Y contains at least one representative of each nontrivial coset of N in G , and
- (v) if $w =_G xy$ with $w \in Y^*, l(w) \leq 3, x \in N$ and $y \in Y \cup \{\varepsilon\}$, then $x \in X$.

Write the finite set X as $X = \{x_1, \dots, x_m\}$. For each $x \in X$ and $y \in Y$, let x^y denote the generator in X that represents the group element $y^{-1}xy$. Similarly if $v = x_{i_1} \cdots x_{i_k} \in X^*$, the symbol v^y denotes the word $x_{i_1}^y \cdots x_{i_k}^y$. An immediate consequence of properties (i)-(v) above is that the language $L := \text{Geo}(G, Z)$ of geodesics of G over Z satisfies the property that $L \subseteq X^* \cup X^*YX^* \cup X^*YX^*YX^*$.

We can now establish the shortlex automaticity of G with respect to a suitable (total) ordering of Z . Choose any such ordering in which the generators in X precede those in Y . Note that every element of G has a geodesic representative in the set $X^* \cup X^*Y$ and since, by properties (iii) and (v), elements of the form yz with $y \in Y$ and $z \in Z$ have an alternative representative of the form $x'y'$ with $x' \in X \cup \{\varepsilon\}$ and $y' \in Y \cup \{\varepsilon\}$, we see that all shortlex minimal representatives have this form. Let L' be the set of words w or wy of this form in which $w \in X^*$ is shortlex minimal. By [9, Thm. 4.3.1], a finitely generated abelian group is shortlex automatic with respect to any finite ordered generating set. It follows (again from properties (iii) and (v)) that L' is the language of an automatic structure for G . The closure of Y under inversion means that elements of G may have two representatives in L' , but by [9, Thm. 2.5.1], we get the shortlex automatic structure for G by intersecting L' with $\text{SL}(G, Z)$.

Turning now to the set $\tilde{L} := \text{ConjGeo}(G, Z)$ of conjugacy geodesics of G over Z , we have $\tilde{L} := \text{ConjGeo}(G, Z) \subseteq L$, and so \tilde{L} can be partitioned as the union of the subsets $\tilde{L}_0 := \tilde{L} \cap X^*, \tilde{L}_1 := \tilde{L} \cap X^*YX^*,$ and $\tilde{L}_2 := \tilde{L} \cap X^*YX^*YX^*$. We show that each \tilde{L}_i is a piecewise testable language.

We start by showing that $\tilde{L}_0 = L \cap X^*$. Suppose that $w \in L \cap X^*$ is not a conjugacy geodesic, and write $w = a_1a_2 \dots a_k$ with $a_i \in X$. Then there exist $n \in N$

and $y \in Y$ such that the element $(ny)^{-1}wny$ of G is represented by a word u that is shorter than w . Since N is abelian we have $u =_G (ny)^{-1}wny =_G y^{-1}wy$. Then $w =_G u^{y^{-1}}$ and by properties (ii)-(iii) the formal conjugate $u^{y^{-1}}$ is a word in X^* satisfying $l(u^{y^{-1}}) = l(u) < l(w)$, which contradicts the fact that w is geodesic. By the proof of [12, Prop. 6.3], $L \cap X^*$ is piecewise excluding, and hence also piecewise testable, so \tilde{L}_0 has the same properties.

An operation on words over Z given by replacement $ayxb \rightarrow ax^{y^{-1}}yb$ with $a, b \in Z^*$, $x \in X$, and $y \in Y$ is called a Y -*shuffle*. An operation on words over X given by a replacement $ux_i x_j v \rightarrow ux_j x_i v$ is a *shuffle*. Note that whenever a word w can be obtained from a word v by means of finitely many applications of these operations, then $v =_G w$, v and w are words over Z of the same length, and furthermore $v \in \tilde{L}_i$ if and only if $w \in \tilde{L}_i$.

Next we turn to \tilde{L}_1 . In this case we further partition the set $\tilde{L}_1 = \cup_{r \in Y} \tilde{L}_{1,r}$ where $\tilde{L}_{1,r} := \{v_1 r v_2 \in \tilde{L} \mid v_1, v_2 \in X^*\}$ for each r in Y . Let $\tilde{\Lambda}_{1,r} := \{w \in X^* \mid wr \in \tilde{L}\}$. It is immediate to see that $\tilde{L}_{1,r}$ is the set of all words that can be obtained from words of the form wr with $w \in \tilde{\Lambda}_{1,r}$ using Y -shuffles.

Next let $\tilde{U}_{1,r} := \tilde{\Lambda}_{1,r} \cap x_1^* x_2^* \cdots x_m^*$, and let

$$U_{1,r} := \{(n_1, \dots, n_m) \in \mathbb{N}_0^m \mid x_1^{n_1} \cdots x_m^{n_m} \notin \tilde{U}_{1,r}\}.$$

Now $U_{1,r}$ has only finitely many elements that are minimal under the ordering on \mathbb{N}_0^m defined by $(n_1, \dots, n_m) \leq (p_1, \dots, p_m)$ if and only if $n_i \leq p_i$ for all $1 \leq i \leq m$ (for a proof see, for example, [9, Lemma 4.3.2]); let $S_{1,r}$ be this finite set of minimal elements. Let $\tilde{S}_{1,r}$ be the set of all words that can be obtained from elements of the set $\{x_1^{n_1} \cdots x_m^{n_m} \mid (n_1, \dots, n_m) \in S_{1,r}\}$ using shuffles, and let $\tilde{S}'_{1,r}$ be the set of all words that can be obtained from elements of the set $\{wr \mid w \in \tilde{S}_{1,r}\}$ via Y -shuffles. Then the set $\tilde{L}_{1,r}$ of Y -shuffles of words in $\tilde{\Lambda}_{1,r}r$ is exactly the set of all words in X^*rX^* that do not contain a piecewise subword lying in the finite set $\tilde{S}'_{1,r}$. So $\tilde{L}_{1,r}$ is piecewise excluding, and hence also piecewise testable, for each $r \in Y$. Therefore \tilde{L}_1 is also piecewise testable.

The proof that \tilde{L}_2 is piecewise testable starts by partitioning $\tilde{L}_2 = \cup_{r,s \in Y} \tilde{L}_{2,r,s}$ where $\tilde{L}_{2,r,s} := \{v_1 r v_2 s v_3 \in \tilde{L} \mid v_1, v_2, v_3 \in X^*\}$ for each r, s in Y . The proof is similar to that for \tilde{L}_1 , but a little more complicated, and we omit the details.

Having established that ConjGeo and SL are regular, it follows that their intersection ConjMinLenSL is also regular. \square

An immediate consequence of the proof above is that for abelian groups piecewise testability of the conjugacy geodesic language holds for every generating set.

Corollary 3.4. *If $G = \langle X \rangle$ is abelian, then $\text{ConjGeo}(G, X)$ is piecewise testable.*

3.3. Groups with locally testable geodesics. This section is devoted to those groups, previously studied in [13], for which $\text{Geo}(G, X)$ is locally testable. Free

groups, free abelian groups and dihedral Artin groups over the standard generators provide examples, as do direct products of such groups.

Informally, whenever k is a positive integer, a language L is k -locally testable if membership of a word in L depends on the nature of its subwords of length k (where by a subword of a word $a_1a_2 \cdots a_n$, we mean either the empty word or a contiguous substring $a_i a_{i+1} \cdots a_j$ for some $1 \leq i \leq j \leq n$); a language L is locally testable if it is k -locally testable for some k .

More precisely, k -local testability is defined as follows. Let $k > 0$ be a natural number. For $u \in X^*$ of length at least k , let $\text{pre}_k(u)$ be the prefix of u of length k , let $\text{suf}_k(u)$ be the suffix of u of length k , and let $\text{sub}_k(u)$ be the set of all subwords of u of length k . If $l(u) < k$, then we define $\text{pre}_k(u) = u$, $\text{suf}_k(u) = u$, and $\text{sub}_k(u) = \emptyset$. We define an equivalence relation \sim_k on X^* to relate u and v when $\text{pre}_{k-1}(u) = \text{pre}_{k-1}(v)$, $\text{suf}_{k-1}(u) = \text{suf}_{k-1}(v)$, and $\text{sub}_k(u) = \text{sub}_k(v)$. A subset $L \subseteq X^*$ is defined to be k -locally testable [5, p. 247] if L is a union of equivalence classes of \sim_k . We refer the reader to [13] and the references cited there for additional information. Here we show the following.

Theorem 3.5. *For a group $G = \langle X \rangle$, if $\text{Geo}(G, X)$ is locally testable, then $\text{ConjGeo}(G, X) = \text{CycGeo}(G, X) \setminus A$, where A is a finite set. Hence $\text{ConjGeo}(G, X)$ is regular.*

Proof. The key ingredient of this proof is [13, Lemma 5.2], which can be reformulated as follows: if $G = \langle X \rangle$ and $\text{Geo}(G, X)$ is locally testable, then there exists $N \in \mathbb{N}$ such that, for each word $w \in X^*$ with $l(w) > N$, there is a cyclic permutation \tilde{w} of w with the property that, if \tilde{w} is a geodesic, then \tilde{w}^j is a geodesic for all $j \geq 1$.

Assume that $\text{Geo}(G, X)$ is locally testable. We claim that each $w \in \text{CycGeo}(G, X)$ with $l(w) > N$ is in fact in $\text{ConjGeo}(G, X)$. Notice first that the cyclic geodesic w lies in $\text{ConjGeo}(G, X)$ if and only if each of its cyclic permutations is in $\text{ConjGeo}(G, X)$. Now let \tilde{w} be the cyclic permutation of w provided by [13, Lemma 5.2]. Suppose that $\tilde{w} \notin \text{ConjGeo}(G, X)$. Then there exist $u, v \in X^*$ such that $\tilde{w} =_G u^{-1}vu$ with $l(v) < l(\tilde{w})$. Notice that $l(\tilde{w}^j) = j l(\tilde{w})$ for all $j \geq 1$. Then

$$|u^{-1}v^j u| \leq 2l(u) + l(v^j) = 2l(u) + j l(v) \leq 2l(u) + (j l(\tilde{w}) - j),$$

which for $j > 2l(u)$ leads to $|\tilde{w}^j| = |u^{-1}v^j u| < j l(\tilde{w}) = l(\tilde{w}^j)$, contradicting the fact that \tilde{w}^j is a geodesic. \square

3.4. Groups with the falsification by fellow traveler property. For a group $G = \langle X \rangle$ and $k \geq 0$, we say that the words $w, w' \in X^*$ k -fellow travel (and write $w \asymp_k w'$), if, for each $i \geq 0$, $|\text{pre}_i(w)^{-1} \text{pre}_i(w')| \leq k$. We say that $G = \langle X \rangle$ satisfies the *falsification by fellow traveler property* (FFTP) if, for some fixed constant k , any nongeodesic word w k -fellow travels with a shorter word. We will write k -FFTP if the above constant needs to be mentioned explicitly. In [24, Prop. 4.1] Neumann and Shapiro showed that a group G satisfying the FFTP over a generating set X has $\text{Geo}(G, X)$ regular. They also show that the FFTP is dependent upon the

generating set. In order to apply this property to conjugacy languages, we begin with a strengthening of the result of [24, Prop. 4.1].

Proposition 3.6. *Suppose that $G = \langle X \rangle$ satisfies the FFTP. Then for every $K \geq 0$ the set*

$$\text{NearGeo}_K := \{w \in X^* : |w| \geq l(w) - K\}$$

is regular.

Proof. Suppose that $w \notin \text{NearGeo}_K$. So $|w| \leq l(w) - (K+1)$. Suppose that G satisfies the k -FFTP. Then there is a sequence of words $w_0 = w, w_1, \dots, w_N$, all representing the same element of G as w where, for each i , $w_i \succ_k w_{i-1}$, $l(w_i) < l(w_{i-1})$, and where $l(w_N) < l(w) - K$. So, assuming that N is minimal with $l(w_N) < l(w) - K$, we have $N \leq K + 1$, and hence $w \succ_{(K+1)k} w_N$. So

$$X^* \setminus \text{NearGeo}_K = \{w : \exists w', l(w') < l(w) - K, w \succ_{(K+1)k} w', w =_G w'\}.$$

This is the projection onto the first coordinate of the intersection of the padded languages $L_1 := \{(w, w') \mid l(w') < l(w) - K\}$ and $L_2 := \{(w, w') \mid w \succ_{(K+1)k} w', w =_G w'\}$; see [9, Section 1.4] for details on languages of padded pairs. The regularity of $X^* \setminus \text{NearGeo}_K$, and hence also of NearGeo_K , now follows from the regularity of L_1 (which we leave to the reader) and of L_2 . The set L_2 is the regular language accepted by the “standard automaton” M_ϵ of [9, Definition 2.3.3], associated to the identity element of G and based on (W, N) , where N is the ball of radius $(K+1)k$ centered at the identity in G , and W is a finite state automaton accepting the language X^* . Briefly, given an automaton M with alphabet $X \cup \{\$\}$, state set S , initial state s_0 and transition function $\delta : S \times X \cup \{\$\} \rightarrow S$ accepting the regular language $L(W)\$\ast = X^*\\ast , then M_ϵ has alphabet $(X \cup \{\$\})^2 \setminus \{(\$, \$)\}$, state set $S \times S \times N$, and initial state (s_0, s_0, ϵ) . When M_ϵ is in state (s, t, g) and reads a letter (a, b) , the automaton goes to the state $(\delta(s, a), \delta(t, b), a^{-1}gb)$ if $a^{-1}gb \in N$, and fails otherwise; a word is accepted by M_ϵ if the automaton finishes in a state of the form (s, t, ϵ) where s and t are accept states of M . \square

Proposition 3.7. *Suppose that $G = \langle X \rangle$ satisfies the FFTP. Suppose that, for some fixed k , L is defined to be the set of words $w \in \text{CycGeo}(G, X)$ for which the following condition holds:*

$$(v \in \text{Cyc}(w) \wedge \alpha \in X^* \wedge l(\alpha) \leq k) \Rightarrow |\alpha^{-1}v\alpha| \geq |v|.$$

Then L is regular.

Proof. For a word $w \in \text{CycGeo}$, we have $w \notin L$ if and only if $w \in \text{Cyc}(\cup_{\alpha \in X^*, l(\alpha) \leq k} L(\alpha))$, where

$$L(\alpha) = \{v \in \text{CycGeo} : |\alpha^{-1}v\alpha| < |v|\}.$$

Since any word v satisfies

$$|\alpha^{-1}v\alpha| < |v| \iff l(\alpha^{-1}v\alpha) - |\alpha^{-1}v\alpha| > 2l(\alpha),$$

we have

$$L(\alpha) = \{v \in \text{CycGeo} : \alpha^{-1}v\alpha \in \text{NearGeo}_{2l(\alpha)}\}.$$

Since G satisfies the FFTP, the languages $\text{NearGeo}_{2l(\alpha)}$ and $\text{Geo} = \text{NearGeo}_0$ are regular by Proposition 3.6, and hence (by Proposition 2.2) so is CycGeo . Standard properties of regular languages now ensure the regularity of $L(\alpha)$.

Since the class of regular languages is closed under finite union, and by cyclic closure (Lemma 2.1), the complement of L in CycGeo given by $\text{Cyc}(\cup_{\alpha \in X^*, l(\alpha) \leq k} L(\alpha))$ is also regular. It follows that L is a regular set. \square

The following is immediate.

Corollary 3.8. *Suppose that $G = \langle X \rangle$ satisfies the FFTP. Suppose that, for some fixed k, s , and for all $r \geq s$, the set $\text{ConjGeo}(G, X) \cap X^r$ is equal to the set of all $w \in \text{CycGeo}(G, X) \cap X^r$ for which*

$$(v \in \text{Cyc}(w) \wedge \alpha \in X^* \wedge l(\alpha) \leq k) \Rightarrow |\alpha^{-1}v\alpha| \geq |v|.$$

Then $\text{ConjGeo}(G, X)$ is regular.

Applying this corollary with $s = 8\delta + 1$ and $k = 2\delta + 1$ gives an alternative proof of Theorem 3.1 that uses FFTP rather than biautomaticity in word hyperbolic groups.

In the following section we use Proposition 3.7 (rather than the corollary) to prove the regularity of ConjGeo for an extra-large type Artin group.

3.5. Artin groups of (extra) large type. An Artin group is defined by the presentation

$$\langle x_1, \dots, x_n \mid m_{ij}(x_i, x_j) = m_{ij}(x_j, x_i) \text{ for each } i \neq j \rangle,$$

where (m_{ij}) is a *Coxeter matrix* (a symmetric $n \times n$ matrix with entries in $\mathbb{N} \cup \{\infty\}$, $m_{ii} = 1, m_{ij} \geq 2, \forall i \neq j$), and where for generators a, a' and $m \in \mathbb{N}$ we define $m(a, a')$ to be the word that is the product of m alternating a s and a' s that starts with a . The set $\{x_1, \dots, x_n\}$ is usually called the standard generating set of the group, but since we want our generating sets to be inverse-closed, we define $X := \{x_1, \dots, x_n\}^{\pm 1}$ to be the *standard generating set*. An Artin group has *large type* if all the integers m_{ij} are at least 3, and *extra-large type* if they are all at least 4.

Holt and Rees [16, Thms. 3.2, 4.1] have shown that the languages $\text{Geo}(G, X)$ and $\text{SL}(G, X)$ are regular. Theorems 3.10 and 3.12 below investigate $\text{ConjGeo}(G, X)$, $\text{ConjMinLenSL}(G, X)$, and $\text{ConjSL}(G, X)$ for Artin groups of (extra-)large type.

First we note that it follows from a result of Mairesse and Mathéus [22, Prop. 4.3] that the set of geodesics for a dihedral Artin group (i.e. an Artin group presented above with $n = 2$) over its standard generating set is locally testable, and so we obtain the following corollary of Theorem 3.5.

Corollary 3.9. *For a dihedral Artin group G over its standard generating set X , the set $\text{ConjGeo}(G, X)$ is regular.*

Theorem 3.10. *Let $G = \langle X \rangle$ be an Artin group of extra-large type with X its standard generating set. Then $\text{ConjGeo}(G, X)$ is regular, and for any ordering of the generators $\text{ConjMinLenSL}(G, X)$ is also regular.*

Proof. Let $n := |X|/2$. For standard generators x_i, x_j , we write $X(i, j) = \{x_i, x_j\}^{\pm 1}$ and $G(i, j) = \langle X(i, j) \rangle$. When $n = 2$, the Artin group is dihedral, and so the result follows from Corollary 3.9.

When $n \geq 3$, $\text{ConjGeo} \setminus \{1\}$ can be written as a union $L_1 \cup L_2 \cup L_3$ of words involving the generators $x_i^{\pm 1}$ for one, two or at least three values of i , respectively. By [17, Prop. 4.1], L_1 is exactly the set of freely reduced powers of generators, and hence is regular. We aim now to show that $\text{ConjGeo}(G(i, j), X(i, j)) \subseteq \text{ConjGeo}(G, X)$. So suppose that w is a 2-generator word involving generators x_i, x_j , and that $w \notin \text{ConjGeo}(G, X)$. If w is non-geodesic in G , then, by results of [16, Section 3], $w \notin \text{ConjGeo}(G(i, j), X(i, j))$, so from on now we assume that w is geodesic in G . Suppose that some generator g conjugates w to a word with a shorter representative. The results proved in [16] show that none of the reductions used to reduce a words to shortlex normal form could involve g if $g \notin X(i, j)$, so $g \in X(i, j)$, and again $w \notin \text{ConjGeo}(G(i, j), X(i, j))$. Otherwise, the element $\pi(w)$ is ‘cyclically reduced’ according to the definition of [17]; that is, for each $a \in X$ we have $|a^{-1}\pi(w)a| \geq |\pi(w)|$. Then we can apply [17, Prop. 5.1], which ensures the existence of words α, u over $X(i, j)$ with $\pi(\alpha^{-1}w\alpha) = \pi(u)$ and $l(u) < l(w)$. So in this case too $w \notin \text{ConjGeo}(G(i, j), X(i, j))$.

Since $\text{ConjGeo}(G(i, j), X(i, j)) \supseteq (L_1 \cup L_2) \cap X(i, j)^*$, it now follows that

$$L_1 \cup L_2 = \cup_{i \neq j} \text{ConjGeo}(G(i, j), X(i, j)).$$

Consequently $L_1 \cup L_2$ is regular.

We shall now apply Proposition 3.7 to show that L_3 is regular. We note that since $\text{ConjGeo}(G, X) \subseteq \text{CycGeo}(G, X)$, we have $L_3 \subseteq \text{CycGeo}(G, X)$. By [16, Thm. 4.1], the language $\text{Geo}(G, X)$ is regular, and so Proposition 2.2 shows that $\text{CycGeo}(G, X)$ also is regular. Standard properties of regular languages now show that the set \tilde{L}_3 of all words in CycGeo involving at least three generators is also regular.

Words in CycGeo are ‘specially cyclically reduced’ according to the criteria of [2, Thm. 4’], and so that theorem applies to show that two words in \tilde{L}_3 represent conjugate elements if and only if cyclic conjugates of them are conjugate via a power of a generator. Then [17, Prop. 6.2] applies to show that those two cyclic conjugates must have the same length unless one of them represents an element of G that is not ‘cyclically reduced’ according to the definition above; that is, its conjugate by some generator represents a shorter element of G . Also, by [17, Props. 4.2, 5.1], a word in \tilde{L}_3 cannot be conjugate to a shorter element of G that involves fewer than three generators.

Hence, for $w \in \tilde{L}_3$, w lies in $\text{ConjGeo}(G, X)$ precisely when none of its cyclic conjugates is shortened by conjugation by a generator; that is precisely when

$$(v \in \text{Cyc}(w) \wedge a \in X) \Rightarrow |a^{-1}va| \geq |v|.$$

In [16, Thm. 4.1] it is also shown that the group G satisfies the FFTP with respect to the generating set X . Now Proposition 3.7 applies to show that the set of all words v that lie in CycGeo and satisfy the above condition is regular. But we have just shown that L_3 is the intersection of this set with the regular set \tilde{L}_3 , so L_3 is regular, and the proof that $\text{ConjGeo}(G, X)$ is regular is complete.

Holt and Rees [16, Thm. 3.2] show that $\text{SL}(G, X)$ is regular for any ordering of the generators, and therefore the intersection $\text{ConjMinLenSL}(G, X) = \text{ConjGeo}(G, X) \cap \text{SL}(G, X)$ is also regular. \square

The remainder of this section is devoted to the proof of Theorem 3.12. We need a technical result about a subset of ConjGeo in the case where G is dihedral.

Lemma 3.11. *Let $G = \langle a, b \mid {}_m(a, b) = {}_m(b, a) \rangle$ be a dihedral Artin group with $m \geq 3$, and let $\Delta = {}_m(a, b)$. Let w be a positive word in a^2 and b^2 . Suppose that w' is any word in the generators and inverses that represents a conjugate of $\pi(w)$ in G . Then $|w'| \geq |w|$ and, if $|w'| = |w|$, then w' is a cyclic conjugate of w or of w^Δ .*

In order to make the proof of the lemma easier to follow, we precede it with a short explanation of the structure of geodesics in dihedral Artin groups; a characterisation is given in [22].

Following [16], we extend the notation for alternating products of generators already introduced above, and define, for any letters (not just generators) a, b , ${}_m(b, a)$ and $(b, a)_m$ to be words of length consisting of alternating a s and b s that begin and end in a , respectively. So (for example) ${}_m(a, b)^{-1} = (b^{-1}, a^{-1})_m$.

Now, for any word w in the generators (and inverses) of the dihedral Artin group G presented as in the statement of the lemma, we define $p(w)$ to be the minimum of m and the length of the longest subword of w of alternating a 's and b 's. Similarly, we define $n(w)$ to be the minimum of m and the length of the longest subword of w of alternating a^{-1} 's and b^{-1} 's. According to [22, Prop. 4.3], w is geodesic if and only if $p(w) + n(w) \leq m$. Furthermore, $\pi(w)$ has more than one geodesic representative if and only if $p(w) + n(w) = m$.

We recall also that the element Δ represented by ${}_m(a, b)$ and ${}_m(b, a)$ is central in G when m is even, whereas $a^\Delta = b$, $b^\Delta = a$ and Δ^2 is central when m is odd. For a word $w = a_1 \cdots a_k$ with $a_i \in \{a, b\}^\pm$, we define w^Δ to be the word $a_1^\Delta \cdots a_k^\Delta$.

PROOF OF LEMMA 3.11:

We prove the result using a minimal counterexample argument, and for the induction to work we need to work under the more general hypothesis that w is a cyclic conjugate of a positive word in a^2 and b^2 . So either w is itself such a word, or else it has the form $x\hat{w}x$, where \hat{w} is a positive word in a^2 and b^2 , and $x \in \{a, b\}$. For such a word w , $p(w) \leq 2$, and $n(w) = 0$. So, by [22], as explained above, w is geodesic.

Suppose that $g^{-1}wg =_G w'$, and let v be a shortest word representing g . Choose w, w' and g to be a counterexample to the theorem in which $|v|$ is minimal.

Then $p(v) \leq m/2$, since otherwise there would be a counterexample with shorter v in which a positive alternating subword u of v of length $p(v)$ is replaced by the geodesic representative of $\Delta^{-1}u$, the prefix v_1 of v before the occurrence of u is replaced by v_1^Δ , and w' is replaced by w'^Δ . Similarly $n(v) \leq m/2$. We assume that v has a positive prefix, that is, that the first letter of v is a or b . (Otherwise the last letter of v^{-1} is a or b , and the argument is similar.) In fact, we may assume without loss that it is a .

If there is any free cancellation in the word $v^{-1}wv$, then we can replace w by a cyclic conjugate and v by a shorter word so, by the minimality of v , the word $v^{-1}wv$ must be freely reduced, and it cannot be a geodesic word. Since any negative alternating subwords of $v^{-1}wv$ must occur within v or v^{-1} , we have $n(v^{-1}wv) \leq m/2$. Since $v^{-1}wv$ is not geodesic, we see (by considering the cases when m is even and odd) that $p(v^{-1}wv) > (m+1)/2$. Hence, since $p(v) \leq m/2$ and $p(w) \leq 2 \leq (m+1)/2$, the longest positive alternating subword of $v^{-1}wv$ must overlap the subwords w and v (and hence, since v begins with a , w must end in b).

Suppose first that m is odd. In this case, for any $0 < p < m$ the equation $p(a, b) =_G \Delta_{m-p}(a^{-1}, b^{-1})$ holds, and we use it below. Now, since $p(v) \leq (m-1)/2$ and $p(v^{-1}wv) > (m+1)/2$, w must end in a^2b and v must have a prefix $u := {}_{(m-1)/2}(a, b)$. Let $w = w_1ab$, where w_1 ends in a . Then

$$\begin{aligned} u^{-1}wu &= (b^{-1}, a^{-1})_{(m-1)/2} w_1 {}_{(m+3)/2}(a, b) \\ &=_G (b, a)_{(m+1)/2} w_1^\Delta {}_{(m-3)/2}(a^{-1}, b^{-1}) \\ &= (b, a)_{(m-3)/2} (abw_1)^\Delta {}_{(m-3)/2}(a^{-1}, b^{-1}). \end{aligned}$$

So, by replacing w by the cyclic conjugate $(abw_1)^\Delta$ of w^Δ , and the prefix u of v by the shorter word ${}_{(m-3)/2}(a^{-1}, b^{-1})$, we find a counterexample with a shorter v .

So now suppose that m is even. In this case, for any $0 < p < m$ the equation $p(a, b) =_G \Delta_{m-p}(b^{-1}, a^{-1})$ holds, and Δ is central. Suppose first that w does not have ab as suffix. Then v must have a prefix $u := {}_{m/2}(a, b)$. Let $w = w_2b$. Then

$$\begin{aligned} u^{-1}wu &= (b^{-1}, a^{-1})_{m/2} w_2 {}_{m/2+1}(b, a) \\ &=_G (a, b)_{m/2} w_2^\Delta {}_{m/2-1}(a^{-1}, b^{-1}) \\ &=_G (a, b)_{m/2} w_2 {}_{m/2-1}(a^{-1}, b^{-1}) \\ &= (b, a)_{m/2-1} bw_2 {}_{m/2-1}(a^{-1}, b^{-1}). \end{aligned}$$

So, by replacing w by its cyclic conjugate bw_2 , and the prefix u of v by the shorter word ${}_{m/2-1}(a^{-1}, b^{-1})$, we find a counterexample with a shorter v .

So now suppose that w does have ab as suffix, and let $w = w_3ab$, where w_3 ends in a . If v has prefix $u := {}_{m/2}(a, b)$ then

$$\begin{aligned} u^{-1}wu &= (b^{-1}, a^{-1})_{m/2} w_3 {}_{m/2+2}(a, b) \\ &=_{G} (a, b)_{m/2} w_3^{\Delta} {}_{m/2-2}(b^{-1}, a^{-1}) \\ &= (a, b)_{m/2} w_3 {}_{m/2-2}(b^{-1}, a^{-1}) \\ &= (a, b)_{m/2-2} abw_3 {}_{m/2-2}(a^{-1}, b^{-1}). \end{aligned}$$

So, by replacing w by its cyclic conjugate abw_3 , and the prefix u of v by the shorter word ${}_{m/2-2}(a^{-1}, b^{-1})$, we find a counterexample with a shorter v .

Finally, if v does not have prefix ${}_{m/2}(a, b)$, then it must have prefix ${}_{m/2-1}(a, b)$, and either v or v^{-1} must contain a negative alternating subword of length $m/2$. In that case, we can replace $g^{-1}wg$ by an equivalent word of length $|g^{-1}wg| - 2$, in which a negative alternating subword of v or v^{-1} is replaced by a positive alternating subword of the same length, and the subword ${}_{m/2+1}(a, b)$ of $g^{-1}wg$ that overlaps w and g is replaced by ${}_{m/2-1}(b^{-1}, a^{-1})$. The resulting word has no positive or negative alternating subwords of length greater than $m/2$, and hence it is geodesic. Since $|v| > 1$, the resulting word is longer than w , and so w , g , and v do not give a counterexample to the theorem, which is a contradiction of the original choice of these words. \square

Theorem 3.12. *Let G be an Artin group of large type, and $X = \{x_1, \dots, x_n\}$ its standard generating set. Then $\text{ConjSL}(G, X)$ is not regular.*

Proof. Suppose first that $n = 2$, so $G = \langle a, b \mid {}_m(a, b) = {}_m(b, a) \rangle$ (with $a = x_1$, $b = x_2$) is a dihedral Artin group with $m \geq 3$. Assume, without loss of generality, that $a < b$. We deduce from Lemma 3.11 that, for $m, n > 2$, the word $a^{2m}b^2a^{2n}b^2$ is in ConjSL if and only if $m \geq n$. Hence $\text{ConjSL}(G, X) \cap (a^2)^*b^2(a^2)^*b^2 = \{a^{2m}b^2a^{2n}b^2 : m \geq n\}$, which is not regular. It follows from the regularity of $(a^2)^*b^2(a^2)^*b^2$ that $\text{ConjSL}(G, X)$ is not regular.

When $n > 2$, we let $a = x_i$ and $b = x_j$ be any two generators in X . Now, as we remarked in the proof of Theorem 3.10, [17, Prop. 5.1] implies that, if a group element $a^{2m}b^2a^{2n}b^2$ with $m, n > 2$ is conjugate in G to a shorter word, then it is conjugate to a shorter word in the subgroup $G(i, j) = \langle a, b \rangle$ of G . (In fact the proof of [17, Prop. 5.1] is valid in general only for extra-large type Artin groups, but it works for large type provided that the element g' defined in that proof has at least three syllables, which is true for the 4-syllable word $a^{2m}b^2a^{2n}b^2$.) So again, assuming $a < b$, we have $\text{ConjSL}(G, X) \cap (a^2)^*b^2(a^2)^*b^2 = \{a^{2m}b^2a^{2n}b^2 : m \geq n\}$, which is not regular, and hence $\text{ConjSL}(G, X)$ is not regular. \square

3.6. Garside groups. *Garside groups* (also known as *small Gaussian groups*) were introduced in [8] as a generalization of the spherical type Artin groups, which include the braid groups. It is shown there that many of the properties of spherical type Artin groups, including having a geodesic biautomatic structure, generalize to

Garside groups. A Garside group G is defined by a finite presentation in which all of the relations are of the form $v = u$, where v and u are positive words in the group generators. So this presentation also defines the associated *Garside monoid* G^+ , and it turns out that this embeds into the Garside group.

There is an element $\Delta \in G^+$ known as the *Garside element*, and the (typically rather large) set S of divisors of Δ in G^+ forms the set of *Garside generators* of G . The geodesic biautomatic structure mentioned above is defined on these generators, and we shall show now that this is also a shortlex automatic structure.

Proposition 3.13. *Let G be a Garside group with Garside element Δ and Garside generators S . Then there is an ordering of $X := S \cup S^{-1}$ with respect to which G is shortlex automatic.*

Proof. We first recall some standard notation and results on Garside groups. For $a, b, c \in G^+$, with $c =_{G^+} ab$, we say that a is a *left divisor* and b is a *right divisor* of c . It can be shown that any two elements $a, b \in G^+$ have a unique ‘largest’ common left divisor $a \wedge b$, which is left-divisible by all of their common left divisors. For $a \in G^+$, we can write $a =_{G^+} (a \wedge \Delta)a'$ for some $a' \in G^+$, and the word $a_1 a_2 a_3 \cdots a_k \in S^*$ where the elements $\hat{a}_1 := a$ and $\hat{a}_{i+1} := \hat{a}'_i$ for $1 < i < k$ satisfy $\hat{a}'_k = 1$ and $a_i := \hat{a}_i \wedge \Delta$ for $1 \leq i \leq k$, is known as the *left greedy normal form* of a .

Let L be the set of words over X of the form $u^{-1}v$, where $u, v \in S^*$, u and v are in left greedy normal form, and $u \wedge v = 1$. It is proved in [8, Thm. 8.1] that L is the language of a geodesic biautomatic structure for G with uniqueness. We shall now define an order of X with respect to which the words in L are the shortlex least representatives of the group elements.

We choose any total ordering of X with the following three properties.

- (i) $s^{-1} < t$ for all $s, t \in S$;
- (ii) if $s, t \in S$ and s is a left divisor of t , then $t < s$.
- (iii) if $s, t \in S$ and s is a right divisor of t , then $s^{-1} < t^{-1}$.

Let w be the shortlex least representative of the group element with normal form $u^{-1}v \in L$. We claim that $w = u^{-1}v$. Since $u^{-1}v$ is geodesic, we have $|w| = |u^{-1}v|$. Since the normal forms of elements of G^+ lie in S^+ , we see that the least $m \geq 0$ with $\Delta^m w \in G^+$ is equal to $|u|$ and the least $n \geq 0$ such that $\Delta^n w^{-1} \in G^+$ is equal to $|v|$. It follows that w must contain exactly $|u|$ generators from S^{-1} and $|v|$ from S because if, for example, it contained $m < |u|$ negative generators, then we would have $\Delta^m w \in G^+$. So, by property (i) of the ordering, we have $w = u'^{-1}v'$ with $u', v' \in S^*$, $|u'| = |u|$, $|v'| = |v|$. So $u' =_G u$ and $v' =_G v$ by [8, Cor. 7.5].

It follows immediately from the definition of the left greedy normal form and from property (ii) of the ordering that v is the shortlex least representative of its group element, and hence $v = v'$. Let $u' = a'_1 a'_2 \cdots a'_m$ with $a'_i \in S$. By [8, Lemma 8.4], if u' is not in normal form then $a'_i a'_{i+1}$ is not in normal form for some i . So, if the normal form word for this element is $a_i a_{i+1}$, then a'_i is a left divisor of a_i , and hence a_{i+1} is a right divisor of a'_{i+1} . But then, by (iii), $a_{i+1}^{-1} a_i^{-1} < a'_{i+1}{}^{-1} a'_i$, contradicting

the shortlex minimality of u'^{-1} . So u' is in normal form and hence $u' = u$, and $w = u^{-1}v$ as claimed. \square

Let G be a Garside group with Garside generators S and $\Delta \in S$. Conjugation by Δ permutes S , and we define $\tau : S \rightarrow S$ by $\tau(x) = \Delta^{-1}x\Delta$ for $x \in S$. The *left greedy normal form* of an element $g \in G$ (which is a different normal form from the one in the proof of Proposition 3.13, agreeing with that normal form only on elements of G^+) has the form $\Delta^p a_1 a_2 \cdots a_k$, where $a_1 a_2 \cdots a_k$ is a positive word in left greedy normal form with $a_i \neq \Delta$ (see, for example, [3, 2.6] for details). So p is maximal such that Δ^p is a left divisor of g . Define $\inf(g) := p$, and $\sup(g) := p + k$.

The *cycling* and *decycling* operations from G to G are defined by

$$\begin{aligned} \mathbf{c}(g) &= \Delta^p a_2 \cdots a_k \tau^{-p}(a_1), \\ \mathbf{d}(g) &= \Delta^p \tau^p(a_k) a_1 a_2 \cdots a_{k-1}. \end{aligned}$$

Note that these operations are equivalent to conjugation by $\tau^{-p}(a_1)$ and a_k^{-1} , respectively. The (de)cycled word is not necessarily in normal form, and it has to be put into normal form before the operation can be applied again. Note that cycling and decycling do not decrease $\inf(g)$, but they may increase it. Similarly they do not increase $\sup(g)$, but they may decrease it.

Let $\inf([g])$ and $\sup([g])$ denote respectively the largest value of $\inf(h)$ and the smallest value of $\sup(h)$ for an element h in the conjugacy class of g .

In [3, Thm. 1], it is proved that, for the braid group B_n , there is a fixed number K (equal to $(n^2 - n)/2 - 1$ or $n - 2$, depending on which set of Garside generators of B_n is used) such that

- (1) if $\inf([g]) > \inf(g)$ then $\inf(\mathbf{c}^k(g)) > \inf(g)$ for some $k \leq K$;
- (2) if $\sup([g]) < \sup(g)$ then $\sup(\mathbf{d}^k(g)) < \sup(g)$ for some $k \leq K$.

A Garside group is called *homogeneous* if $l(v) = l(u)$ for each of its defining relations $u = v$. This implies that the positive words in the group generators that represent an element $g \in G^+$ all have the same length. The spherical type Artin groups are homogeneous Garside groups, but there are examples of inhomogeneous Garside groups.

It is observed in [10, Section 3.2] that the proof of [3, Thm. 1] works for all homogeneous Garside groups, but it relies heavily on elements of G^+ having a well-defined length in G^+ , so it does not appear to extend to general Garside groups. It is proved in [25, Props. 3.7, 3.10] that [3, Thm. 1] holds for general Garside groups, but without the bound on k . For the remainder of this section, we assume that G is homogeneous.

As observed above, G is automatic with a geodesic normal form on $X := S \cup S^{-1}$. It is pointed out in [3, proof of Corollary 3] that the geodesic length $|g|$ of g over X is equal to $\max(\sup(g), \sup(g) - \inf(g), -\inf(g))$; in fact $|g|$ is equal to $\sup(g)$ when g is positive, $-\inf(g)$ when g is negative, and $\sup(g) - \inf(g)$ otherwise.

So, if g is conjugate in G to a shorter element h , then at least one of $\inf(h) > \inf(g)$ and $\sup(h) < \sup(g)$ is true. In the first case, we are in case (1) above, and so for

some $k \leq K$, we have $\inf(\mathbf{c}^k(g)) > \inf(g)$. We can deduce that $|\mathbf{c}^k(g)| < |g|$ except possibly when g is positive and $|g| = \sup(g)$. But in this case, we must have $\sup(h) < |g| = \sup(g)$, and so we are also in case (2), and can deduce that $|\mathbf{d}^{k'}(g)| = \sup(\mathbf{d}^{k'}(g)) < \sup(g) = |g|$ for some $k' \leq K$. In the second case, we prove the identical result analogously.

Hence, since \mathbf{c}^k and \mathbf{d}^k correspond to conjugation by group elements of length k , we have the following.

Proposition 3.14. *Let G be a homogeneous Garside group with Garside generators S . If $w \in (S \cup S^{-1})^*$, and there exists $h \in G$ with $|h^{-1}wh| < |w|$, then there exists such an h of length at most K .*

It is proved in [15] that G satisfies the FFTP over the Garside generators, and so Propositions 3.14 and 3.13 together with Corollary 3.8 implies the following.

Theorem 3.15. *If G is a homogeneous Garside group with Garside generators S and $X := S \cup S^{-1}$, then $\text{ConjGeo}(G, X)$ is regular, and there is an ordering of X for which $\text{ConjMinLenSL}(G, X)$ is regular. This holds, in particular, for spherical type Artin groups.*

4. SHORTLEX LANGUAGES AND SPHERICAL GROWTH SERIES

In [27] and [26], Rivin proved that the spherical conjugacy growth series $\tilde{\sigma}(G)$ is not rational for nonabelian free groups on their free generating sets, and made the following conjecture, one direction of which we shall prove in this section.

Conjecture 4.1. [27, Conjecture 13.1] *Let G be a word hyperbolic group. Then $\tilde{\sigma}(G)$ is rational if and only if G is virtually cyclic.*

Theorem 4.2. *Let G be a virtually cyclic group. Then for all generating sets of G the set of shortlex conjugacy normal forms ConjSL is regular and hence the spherical conjugacy growth series $\tilde{\sigma}$ is rational.*

Proof. We may assume that G is infinite. Then there exists $H \trianglelefteq G$, $H = \langle x \rangle \cong \mathbb{Z}$, with G/H finite. Let $C := C_G(H)$ be the centralizer of H in G . Then the conjugation action of G on H defines a map $G \rightarrow \text{Aut}(\mathbb{Z})$ with kernel C and so $|G : C| \leq 2$. For $g \in G \setminus C$, we have $x^{-1}gx = gx^2$, and hence the coset Hg is either a single conjugacy class in $\langle H, g \rangle$ or a union of two such classes, containing g and gx . So $G \setminus C$ consists of finitely many conjugacy classes of G . On the other hand, for $g \in C$, $|G : C_G(g)|$ is finite, so C is a union of infinitely many finite classes.

Since $\text{ConjSL} \cap (G \setminus C)$ is finite, it is regular, and to prove regularity of ConjSL it is enough to show that $\text{ConjSL} \cap C$ is regular.

Let T be a transversal of H in G . Then for each $c \in C$, the conjugacy class of c is $\{t^{-1}ct \mid t \in T\}$, and hence any word w with $\pi(w) = c$ is in ConjSL if and only if there does not exist $t \in T$ for which $t^{-1}wt$ has a representative v with $v <_{sl} w$.

Now G is word hyperbolic, and we recall from the proof Theorem 3.1 that the set

$$L_1(t) := \{(u, v) : u, v \in \text{Geo}, \pi(v) = \pi(t^{-1}ut)\}$$

is regular for any $t \in T$, as is the set Geo . So $\text{ConjSL} \cap C$ is the intersection of $\pi^{-1}(C)$ with

$$\text{Geo} \setminus \bigcup_{t \in T} (\{u \in \text{Geo} : \exists v \in \text{Geo} \text{ such that } (u, v) \in L_1(t), v <_{sl} u\}).$$

Now standard arguments for regular sets show that this set regular, and $|G : C|$ finite implies that $\pi^{-1}(C)$ is regular, so $\text{ConjSL} \cap C$ is also regular. \square

5. BEHAVIOR OF CONJUGACY LANGUAGES FOR VIRTUALLY ABELIAN GROUPS

In this section we present two examples of virtually abelian groups and discuss their conjugacy languages. Our main goal is to demonstrate that regularity of the conjugacy languages can occur even when SL and Geo , or others among the conjugacy languages, are not regular, and to show dependence of regularity of the three conjugacy languages on the generating sets of the groups. However, we recall that we proved in Proposition 3.3 that any virtually abelian group has some generating set with respect to which both Geo and ConjGeo are regular and an ordering on that generating set for which both SL and ConjMinLenSL are regular.

We begin by considering an index 2 extension G of \mathbb{Z}^2 , where G is the semidirect product $\mathbb{Z}^2 \rtimes \mathbb{Z}/2\mathbb{Z}$, and the $\mathbb{Z}/2\mathbb{Z}$ action swaps the generators of \mathbb{Z}^2 ; that is,

$$G = \langle a, b, t \mid t^2 = 1, ab = ba, a^t = b \rangle.$$

Cannon [24, p. 268] noted that the language of geodesics for G can be either regular or non-regular, depending on the generating set. In the following two propositions we explore Cannon's generating sets in the case of conjugacy languages.

Proposition 5.1. *Let $G \cong \mathbb{Z}^2 \rtimes \mathbb{Z}/2\mathbb{Z}$ be as defined above, with the generating set $Z = \{a^{\pm 1}, b^{\pm 1}, t\}$. Then $\text{ConjSL}(G, Z)$ is not regular with respect to any ordering on Z , but the spherical conjugacy growth series is given by the rational function*

$$\tilde{\sigma} = \frac{(1+z)(1+2z+3z^2-z^3-z^4)}{(1-z^2)^2}.$$

Moreover $\text{ConjGeo}(G, Z)$ and $\text{ConjMinLenSL}(G, Z)$ are regular.

Proof. Note that, since $t = t^{-1}$, the generating set Z is inverse-closed. With respect to any ordering on Z with $a^{\pm 1} < b^{\pm 1} < t$, the shortlex language is

$$\text{SL}(G, Z) = \{a^i b^j t^\epsilon \mid i, j \in \mathbb{Z}, \epsilon \in \{0, 1\}\}.$$

Using this representation of the group elements, we compute the conjugacy classes as

$$[a^i b^j]_c = \{a^i b^j, a^j b^i\}, \quad [a^i b^j t]_c = \{a^{i+k} b^{j-k} t \mid k \in \mathbb{Z}\}.$$

Thus, using this ordering, the shortlex conjugacy language is the non-regular set

$$\begin{aligned} \text{ConjSL}(G, Z) = & \{a^i b^j \mid |i| > |j|, i, j \in \mathbb{Z}\} \cup \{a^i b^i \mid i \in \mathbb{Z}\} \cup \{a^i b^{-i} \mid i \in \mathbb{N}\} \\ & \cup \{a^i t \mid i \in \mathbb{Z}\}, \end{aligned}$$

For any ordering of Z , the intersection of $\text{ConjSL}(G, Z)$ with the regular set $\{a, b\}^*$ is either $\{a^i b^j \mid i > j \geq 0\}$ or $\{b^i a^j \mid i > j \geq 0\}$, and so $\text{ConjSL}(G, Z)$ is never regular. However, the above expression for ConjSL gives

$$\tilde{\sigma} = 1 + 3z + \sum_{k=1}^{\infty} (4k + 3)z^{2k} + \sum_{k=1}^{\infty} (4k + 4)z^{2k+1},$$

yielding the required rational function for $\tilde{\sigma}$.

Finally, applying the structure of the conjugacy classes again together with the geodesic language $\text{Geo}(G, Z) = \bigcup_{\zeta, \eta \in \{\pm 1\}} \{a^\eta, b^\zeta\}^* \cup \{a^\eta, b^\zeta\}^* t \{a^\zeta, b^\eta\}^*$ yields the conjugacy geodesic and shortlex minimal conjugacy languages (where the latter is computed using the ordering at the start of this proof) as

$$\begin{aligned} \text{ConjGeo}(G, Z) &= \bigcup_{\eta, \zeta \in \{\pm 1\}} \{a^\eta, b^\zeta\}^* \cup \bigcup_{\eta \in \{\pm 1\}} \{a^\eta, b^\eta\}^* t \{a^\eta, b^\eta\}^* \\ \text{ConjMinLenSL}(G, Z) &= \bigcup_{\eta, \zeta \in \{\pm 1\}} (a^\eta)^* (b^\zeta)^* \cup \bigcup_{\eta \in \{\pm 1\}} (a^\eta)^* (b^\eta)^* t. \end{aligned}$$

□

The other generating set for $G = \mathbb{Z}^2 \rtimes \mathbb{Z}/2\mathbb{Z}$ considered by Cannon in [24] is $\{a, c, d, t\}^{\pm 1}$ where $c = a^2$ and $d = ab$, with presentation

$$G = \langle a, c, d, t \mid ad = da, c = a^2, t^2 = 1, tat = a^{-1}d \rangle.$$

In the proof below we use these generators, including a few more details for Cannon's proof that Geo is not regular.

We also require some more notation. Following [20], we define the insertion of w into z , denoted by $z \leftarrow w$, to be the set of all words of the form $z' w z''$, where $z = z' z''$. Given languages $L_1, L_2 \subseteq X^*$, we define also the insertion of L_2 into L_1 ,

$$L_1 \leftarrow L_2 := \{z \leftarrow w \mid z \in L_1, w \in L_2\}.$$

Observe that, if L_1 and L_2 are regular, then so is $L_1 \leftarrow L_2$.

Proposition 5.2. *Let $G \cong \mathbb{Z}^2 \rtimes \mathbb{Z}/2\mathbb{Z}$ be as defined above, with generating set $X = \{a^{\pm 1}, c^{\pm 1}, d^{\pm 1}, t\}$. Then $\text{ConjGeo}(G, X)$ is regular, but $\text{Geo}(G, X)$ is not. Moreover, for some orderings of the generating set, $\text{ConjSL}(G, X)$ and $\text{ConjMinLenSL}(G, X)$ are regular, but $\text{SL}(G, X)$ is not.*

Proof. The group $G = \mathbb{Z}^2 \rtimes \mathbb{Z}/2\mathbb{Z}$ can be embedded in Euclidean 3-space \mathbb{R}^3 using the function $f : G \rightarrow \mathbb{R}^3$ defined by $f(g) := (i_g, j_g, \epsilon_g)$ where $a^{i_g} b^{j_g} t^{\epsilon_g}$ (with $b = tat$) is the shortlex normal form over Z for the element g of G . Multiplication by $a^{\pm 1}$, $c^{\pm 1}$, or $d^{\pm 1}$ has the effect of adding a horizontal vector (parallel to the $z = 0$ plane); in particular, for any $g \in G$ and $\mu \in \{1, -1\}$, we have

$$\begin{aligned} f(ga^\mu) &= f(g) + \mu(1 - \epsilon_g, \epsilon_g, 0), & f(gc^\mu) &= f(g) + 2\mu(1 - \epsilon_g, \epsilon_g, 0), \\ f(gd^\mu) &= f(g) + \mu(1, 1, 0). \end{aligned}$$

On the other hand, multiplication by t adds a vertical vector:

$$f(gt) = f(g) + (1 - 2\epsilon_g)(0, 0, 1).$$

Using the taxicab metric on \mathbb{R}^3 (defined by the norm $\|(x, y, z)\| = |x| + |y| + |z|$), we see that the maximum distance between $f(g)$ and $f(gx)$ due to multiplication by a single generator $x \in X$ is 2.

For the remainder of the proof we order the generating set X by $a < c < A < C < d < D < t$, where for ease of notation we use a capital letter A to denote the inverse a^{-1} , etc.

First we show that the languages $\text{Geo}(G, X)$ and $\text{SL}(G, X)$ are not regular. Consider the element $g := a^{2m}b^{2n}$ in G , where $m, n \geq 1$, and let w be any word representing g . Then w must contain an even (possibly zero) number of occurrences of t , and, since the point $f(g) = (2m, 2n, 0)$ has taxicab metric distance $2m + 2n$ from the identity of the group, and multiplication by t does not affect the the first two coordinates, we see that w must involve at least $m + n$ letters from $\{a, c, d\}^{\pm 1}$. If $m \geq n$, then the word $c^{m-n}d^{2n}$ of length $m + n$ is a geodesic representative for g , and no geodesic representative can contain t . But if $m < n$ and w does not contain t , then w must contain at least $2n$ occurrences of d since the y -coordinate of $f(g)$ is $2n$; then $c^{m-n}d^{2n}$ is a shortest representative of g over $\{a, c, d\}^{\pm 1}$. However, the shorter word $c^m t c^n t$ also represents g , and is geodesic. Moreover, any word of length $m + n + 2$ representing g must contain two occurrences of t and $m + n$ occurrences of letters among c, d , with at most m occurrences of c before the first t , and so $c^m t c^n t$ is the shortlex normal form for g . Hence

$$\text{Geo}(G, X) \cap c^* t c^* t = \text{SL}(G, X) \cap c^* t c^* t = \{c^m t c^n t \mid m < n\}.$$

Since this last set is not regular, but the set of regular languages is closed under intersection, we conclude that neither $\text{Geo}(G, X)$ nor $\text{SL}(G, X)$ is regular.

We shall now deduce the regularity of $\text{ConjGeo}(G, X)$, $\text{ConjMinLenSL}(G, X)$, and $\text{ConjSL}(G, X)$ from the structure of the conjugacy classes for this group discussed in the proof of Proposition 5.1. (We note that $\text{ConjSL}(G, X)$ and $\text{ConjMinLenSL}(G, X)$ are also regular with various other orderings of the generators; we chose the ordering in this proof because it results in the least complicated description.)

We begin by computing the portions of these three languages from conjugacy classes of the form $[a^m b^n]_c$ when $0 \leq m, n$; without loss of generality we assume $m \leq n$. Using similar arguments to those above shows that geodesic representatives of the group element $a^n b^m$ in this conjugacy class have length $\lceil (m + n)/2 \rceil$ and have the form $(c^* d^*)^*$ for $m + n$ even and $(c^* d^*)^* a (c^* d^*)^*$ for $m + n$ odd. However, the geodesic representatives of the other element $a^m b^n$ of this conjugacy class are strictly longer; when $n - m \geq 3$ they all involve two occurrences of t , and geodesic representatives of $a^m b^{m+1}$ and $a^m b^{m+2}$ are given by Ad^{m+1} and Cd^{m+2} , respectively. Thus the only element of $[a^m b^n]_c$ with minimal length up to conjugacy is $a^n b^m$. A similar argument shows that the only group element in $[A^m B^n]_c$ for $0 \leq m \leq n$ with minimal length up to conjugacy is $A^n B^m$. Thus when m and n are both nonnegative,

the portion of the set $\text{ConjGeo}(G, X)$ arising from the conjugacy classes $[a^m b^n]_c$ and $[A^m B^n]_c$ is

$$(\{c, d\}^* \leftarrow \{\varepsilon, a\}) \cup (\{C, D\}^* \leftarrow \{\varepsilon, A\})$$

and the portion of both $\text{ConjMinLenSL}(G, X)$ and $\text{ConjSL}(G, X)$ is

$$\{\varepsilon, a\}c^*d^* \cup \{\varepsilon, A\}C^*D^*.$$

It is more complicated to describe the contributions to the three conjugacy languages from $[a^m B^n]_c$ in the case that $0 < m, n$, and we shall do this only briefly. Note first that the sets of geodesic representatives of b^k for $k \geq 1$ are: $\{Ad, dA\}$ for $k = 1$; $\{Cd^2, dCd, d^2C, tct\}$ for $k = 2$; $\{tc^{k/2}t\}$ for $k \geq 4$ even; and $t(c^{(k-1)/2} \leftarrow a)t$ for $k \geq 3$ odd.

In the case that $3 \leq m, n$, geodesics representing both elements $a^m B^n$ and $A^n b^m$ of this class require two occurrences of the letter t , and both elements are of minimal length up to conjugacy. The contribution to $\text{ConjGeo}(G, X)$ from these conjugacy classes is the regular set $L_1 \cup L_2 \cup L_3 \cup L_1^- \cup L_2^- \cup L_3^-$, where

$$\begin{aligned} L_1 &= [c^+ \leftarrow \{a, c\}] \leftarrow [t(C^+ \leftarrow \{A, C\})t], \\ L_2 &= (c^+ \leftarrow tC^2C^*t) \leftarrow d, \\ L_3 &= (c^2c^* \leftarrow tC^+t) \leftarrow D. \end{aligned}$$

and L_1^-, L_2^-, L_3^- are defined similarly to L_1, L_2, L_3 , but with all generators replaced by their inverses. The words in $\text{ConjMinLenSL}(G, X)$ are the shortlex normal forms of all of the elements in the classes $[a^m B^n]_c$ with $3 \leq m, n$, which we collect in the regular expression

$$\{c^2, ac\}c^*t\{C^2, AC\}C^*t \cup \{C^2, AC\}C^*t\{c^2, ac\}c^*t.$$

Similarly, the intersection of this last set with $\text{ConjSL}(G, X)$ is given by the regular expression $\{c^2, ac\}c^*t\{C^2, AC\}C^*t$.

Suppose, on the other hand, that either $m \in \{1, 2\}$ and $n \geq 3$, or $m \geq 3$ and $n \in \{1, 2\}$. Then the conjugacy class $[a^m B^n]_c$ contains a unique shortest group element, namely $A^n b^m$ when $m \leq 2$ or $a^m B^n$ when $n \leq 2$. The words of $\text{ConjGeo}(G, X)$ from classes of this type are in the regular set $L_4 \cup L_5 \cup L_4^- \cup L_5^-$, where

$$\begin{aligned} L_4 &= (c^2c^* \leftarrow D) \leftarrow \{\varepsilon, a\}, \\ L_5 &= ((c^2c^* \leftarrow D) \leftarrow D) \leftarrow \{a, c\}. \end{aligned}$$

and L_4^-, L_5^- are similarly defined in terms of A, C, d . The portion of both $\text{ConjMinLenSL}(G, X)$ and $\text{ConjSL}(G, X)$ from these classes is given by the regular expression

$$\{a, \varepsilon\}c^2c^*D \cup \{a, c\}c^2c^*D^2 \cup \{A, \varepsilon\}C^2C^*d \cup \{A, C\}C^2C^*d^2.$$

The finitely many classes $[a^m B^n]_c$ when both m and n are at most 2 give rise to finite subsets of the three conjugacy languages.

Finally, we consider the conjugacy classes $[a^s t]_c$ for $s \in \mathbb{Z}$. Recall that this class contains all group elements of the form $a^m b^n t$ for $m, n \in \mathbb{Z}$ and $m + n = s$. Suppose first that $s > 0$. Geodesic representatives of these elements all contain a single t .

Geodesic representatives of $a^m b^n t$ have length $\lceil s/2 \rceil + 1$ when $m, n \geq 0$, but are longer otherwise. Hence $\text{ConjGeo}(G, X)$ consists of the geodesic representatives of $a^m b^n t$ with $m, n \geq 0$. The case in which $s < 0$ is similar. Thus the contribution to $\text{ConjGeo}(G, X)$ from classes $[a^s t]_c$ is

$$(\{c, d\}^* t \{c, d\}^* \leftarrow \{\varepsilon, a\}) \cup (\{C, D\}^* t \{C, D\}^* \leftarrow \{\varepsilon, A\}).$$

The subsets of $\text{ConjMinLenSL}(G, X)$ and $\text{ConjSL}(G, X)$ arising from these conjugacy classes are defined by regular expressions

$$\{\varepsilon, a\}c^* \{\varepsilon, d\}tc^* \cup tac^* \cup \{\varepsilon, A\}C^* \{\varepsilon, D\}tC^* \cup tAC^* \quad \text{and} \quad \{\varepsilon, a\}c^* t \cup \{\varepsilon, A\}C^* t,$$

respectively. \square

In the next two propositions we change the virtually abelian group under consideration to a semidirect product group $K = \mathbb{Z}^2 \rtimes D_8$. One of the generating transpositions of D_8 acts by swapping the generators of \mathbb{Z}^2 , and the other one fixes the generators; that is,

$$K = \langle a, b, t, u \mid t^2 = u^2 = (tu)^4 = 1, ab = ba, a^t = b, a^u = a, a^u = b \rangle.$$

The index 4 subgroup $\langle a, b, t \rangle$ of K is the group G considered in Propositions 5.1 and 5.2.

Proposition 5.3. *Let $K \cong \mathbb{Z}^2 \rtimes D_8$ be as defined above, where the generators $Z' = \{a^{\pm 1}, b^{\pm 1}, t, u\}$ are ordered with $a^{\pm 1} < b^{\pm 1} < t < u$. Then $\text{Geo}(K, Z')$, $\text{SL}(K, Z')$, $\text{ConjGeo}(K, Z')$, and $\text{ConjMinLenSL}(K, Z')$ are regular languages, but $\text{ConjSL}(G, Z')$ is not.*

Proof. The shortlex language is

$$\text{SL}(K, Z') = \{a^i b^j v \mid i, j \in \mathbb{Z}, v \in \{1, t, u, tu, ut, tut, utu, tutu\}\}$$

and the geodesic language $\text{Geo}(K, Z')$ is $\bigcup_{\eta, \zeta \in \{\pm 1\}} (L_1^{\eta, \zeta} \cup L_2^{\eta, \zeta} \cup L_3^{\eta, \zeta})$, where

$$\begin{aligned} L_1^{\eta, \zeta} &= \{a^\eta, b^\zeta\}^* \leftarrow \{\varepsilon, u\}, \\ L_2^{\eta, \zeta} &= (\{a^\eta, b^\zeta\}^* \leftarrow \{\varepsilon, u\}) \leftarrow t(\{a^\zeta, b^\eta\}^* \leftarrow u)t, \\ L_3^{\eta, \zeta} &= \{a^\eta, b^\zeta\}^* t \{a^\zeta, b^\eta\}^* \leftarrow \{\varepsilon, u\}. \end{aligned}$$

By successively conjugating shortlex normal forms by generators, we find that the conjugacy classes are given by

$$\begin{aligned} [a^i b^j]_c &= \{a^i b^j, a^j b^i\}, \quad [a^i b^j t]_c = [a^i b^j utu]_c = \{a^{i+k} b^{j-k} v \mid k \in \mathbb{Z}, v \in \{t, utu\}\}, \\ [a^i b^j u]_c &= [a^j b^i tut]_c = \{a^i b^j u, a^j b^i tut\}, \quad [a^i b^j tutu]_c = \{a^i b^j tutu, a^j b^i tutu\}, \\ [a^i b^j tu]_c &= [a^i b^j ut]_c = \{a^{i+k} b^{j-k} v \mid k \in \mathbb{Z}, v \in \{tu, ut\}\}. \end{aligned}$$

As a consequence,

$$\begin{aligned} \text{ConjGeo}(K, Z') &= \bigcup_{\eta, \zeta \in \{\pm 1\}} (L_1^{\eta, \zeta} \cup L_2^{\eta, \zeta}) \cup \left(\bigcup_{\eta \in \{\pm 1\}} L_3^{\eta} \right), \quad \text{where} \\ L_2^{\eta, \zeta} &= (\{a^\eta, b^\zeta\}^* \leftarrow u) \leftarrow t(\{a^\zeta, b^\eta\}^* \leftarrow u)t, \\ L_3^{\eta} &= (\{a^\eta, b^\eta\}^* \leftarrow t) \leftarrow \{1, u\}, \end{aligned}$$

and

$$\text{ConjMinLenSL}(K, Z') = \bigcup_{\eta, \zeta \in \{\pm 1\}} (a^\eta)^*(b^\zeta)^*\{1, u, tutu\} \cup \bigcup_{\eta \in \{\pm 1\}} \{a^\eta\}^*(b^\eta)^*\{t, tu, ut\}.$$

However, just as for the finite index subgroup G of K in Proposition 5.1, the intersection $\text{ConjSL}(K, Z') \cap a^*b^* = \{a^i b^j \mid i > j\}$ is not regular, and so this shortlex conjugacy language is not regular. \square

Proposition 5.4. *Let*

$$\begin{aligned} K &= \langle a, c, d, t, u \mid \\ &\quad t^2 = u^2 = (tu)^4 = 1, ad = da, c = a^2, tat = a^{-1}d, uau = a, udu = d \rangle \\ &\cong \mathbb{Z}^2 \rtimes D_8, \end{aligned}$$

with generating set $X' = \{a^{\pm 1}, c^{\pm 1}, d^{\pm 1}, t, u\}$. Then $\text{Geo}(K, X')$ and $\text{ConjGeo}(K, X')$ are not regular. Moreover, if the set X' is ordered by $a < c < a^{-1} < c^{-1} < d < d^{-1} < t < u$, then none of the languages $\text{SL}(K, X')$, $\text{ConjMinLenSL}(K, X')$, and $\text{ConjSL}(K, X')$ is regular.

Proof. In order to analyze geodesic representatives for elements of K over X' , we use similar arguments to those in the proof of Proposition 5.2, in that we use an embedding $f : K \rightarrow \mathbb{R}^2 \times D_8$ with the map $f(g) := (i_g, j_g, h_g)$, where $g = a^{i_g} b^{j_g} h_g$ with $b = a^t$ and $h_g \in \langle t, u \rangle \cong D_8$. Geodesic representatives over X' of the elements of the subgroup $\mathbb{Z}^2 \rtimes \mathbb{Z}/2\mathbb{Z} = \langle X \rangle$ of K where $X = \{a^{\pm 1}, c^{\pm 1}, d^{\pm 1}, t\}$ cannot contain an occurrence of the letter u , and so the proof of Proposition 5.2 also shows that $\text{Geo}(K, X')$ and $\text{SL}(K, X')$ are not regular.

To show further that $\text{ConjGeo}(K, X')$ and $\text{ConjMinLenSL}(K, X')$ are not regular, consider the word $w_{mn} := c^m t c^n t u$ for $m, n \geq 0$.

When $n \leq m$, then (as in the proof of Proposition 5.2) $w_{mn} =_K c^{m-n} d^{2n} u$, and so $w_{mn} \notin \text{Geo}(K, X')$.

When $m < n$, we claim that $w_{mn} \in \text{ConjMinLenSL}(K, X')$; this will imply that the intersections of each of $\text{ConjGeo}(K, X')$ and $\text{ConjMinLenSL}(K, X')$ with the regular language $c^* t c^* t u$ are not regular; hence neither conjugacy language is regular.

The conjugacy class of w_{mn} is $[w_{mn}]_c = [a^{2m} b^{2n} u]_c = \{a^{2m} b^{2n} u, a^{2n} b^{2m} t u t\}$, from the proof of Proposition 5.3. Using the embedding above, we have $f(a^{2n} b^{2m} t u t) = (2n, 2m, t u t)$. Since we need at least $m + n$ letters in $\{a, c, d\}^{\pm 1}$ to reach this point, and $t u t$ is a geodesic word in $\langle t, u \rangle \cong D_8$, every geodesic representative of $a^{2n} b^{2m} t u t$ has length at least $m + n + 3$.

On the other hand, $f(w_{mn}) = f(a^{2m}b^{2n}u) = (2m, 2n, u)$. As in the proof of Proposition 5.2, in order to reach a point in $\mathbb{R}^2 \times D_8$ with first two coordinates $(2m, 2n)$ we need at least $m + n$ occurrences of letters in $\{a, c, d\}^{\pm 1}$. Suppose for a contradiction that v is a word with $v =_K w_{mn}$ and $l(v) < l(w_{mn})$. So $l(v) \leq m + n + 2$ and v involves at least $m + n$ letters in $\{a, c, d\}^{\pm 1}$. Since v is not in the normal subgroup $\langle a, c, d, t, (tu)^2 \rangle$ of index 2 in K , the number of occurrences of u in v must be odd, and hence must be exactly 1. We see similarly that the number of occurrences of t is even, so it must be 0. So deleting the single occurrence of u from v would give a word over $\{a, c, d\}^{\pm 1}$ of length at most $m + n + 1$ for $a^{2m}b^{2n}$ which, as we saw in Proposition 5.2, does not exist when $m < n$. Thus the element $a^{2m}b^{2n}u$ of $[w_{mn}]_c$ is of minimal length up to conjugacy, and the word w_{mn} representing this element lies in $\text{ConjGeo}(K, X')$. All geodesic representatives of this element lie in $\{c, d, t\}^* \leftarrow u$, and among these the word with the longest initial prefix in c^* is w_{mn} . Therefore $w_{mn} \in \text{ConjMinLenSL}(K, X')$ as well, finishing the claim.

In order to prove that $\text{ConjSL}(K, X')$ is not regular, we consider the word $v_{mn} := c^m t c^n u t u$ for $m, n \geq 0$. The corresponding conjugacy class from the proof of Proposition 5.3 is $[v_{mn}]_c = \{a^{2m}b^{2n}tutu, a^{2n}b^{2m}tutu\}$. The words $c^m t c^n u t u$ and $c^n t c^m u t u$ are the shortlex least words representing the elements $a^{2m}b^{2n}tutu$ and $a^{2n}b^{2m}tutu$, respectively. Thus the element of $\text{ConjSL}(K, X')$ corresponding to this conjugacy class is the representative with the longest initial string of the letter c . That is,

$$\text{ConjSL}(K, X') \cap c^* t c^* u t u = \{c^m t c^n u t u \mid m \geq n\},$$

which is not regular. □
