# CONSTRUCTIONS OF DISJOINT STEINER TRIPLE SYSTEMS 

JEAN DOYEN ${ }^{1}$

#### Abstract

Let $D^{*}(v)$ denote the maximum number of pairwise disjoint and isomorphic Steiner triple systems of order $v$. The main result of this paper is a lower bound for $D^{*}(v)$, namely $D^{*}(6 t+3) \geqq$ $4 t-1$ or $4 t+1$ according as $2 t+1$ is or is not divisible by 3 , and $D^{*}(6 t+1) \geqq t / 2$ or $t$ according as $t$ is even or odd. Some other related problems are studied or proposed for study.

1. Introduction and historical note. Given a finite nonempty set $S$ of $v$ elements (called points), a Steiner triple system of order $v$ on $S$ is a collection $\mathscr{S}$ of subsets of $S$ (called lines) such that every line has exactly 3 points and every pair of points is contained in one and only one line. Any Steiner triple system is also a balanced incomplete block design with parameters $v, k=3$ and $\lambda=1$ (see for instance Hall [10, Chapter 15]).

Kirkman [11] proved in 1847 that a necessary and sufficient condition for the existence of a Steiner triple system (briefly STS) of order $v$ is $v \equiv 1$ or $3(\bmod 6)$. An STS of order $v$ is sometimes denoted simply by $S(v)$.

Let $\mathscr{S}$ and $\mathscr{S}^{\prime}$ be two STS on the same set $S$ of points. $\mathscr{S}$ and $\mathscr{S}^{\prime}$ are called disjoint if $\mathscr{S} \cap \mathscr{S}^{\prime}=\varnothing$, that is if they have no line in common. According to [8], the construction of disjoint STS might be useful in the design of certain statistical experiments.

Let us denote by $D(v)$ the maximum number of pairwise disjoint $S(v)$ that can be constructed on a set $S$ of $v$ points. As $S$ contains $v(v-1)(v-2) / 6$ subsets of cardinality 3 and as any $S(v)$ contains exactly $v(v-1) / 6$ lines, we have $D(v) \leqq v-2$, except of course if $v=1$. We shall denote by $D^{*}(v)$ the maximum number of pairwise disjoint and isomorphic $S(v)$ that can be constructed on $S$. Obviously, $1 \leqq D^{*}(v) \leqq D(v)$.
It is clear that

$$
D^{*}(1)=D(1)=1 \quad \text { and } \quad D^{*}(3)=D(3)=1 .
$$

Cayley [6] proved in 1850 that $D^{*}(7)=D(7)=2$. The following collections

Key words and phrases. Steiner triple systems, balanced incomplete block designs.
${ }^{1}$ Aspirant du Fonds National belge de la Recherche Scientifique.
of subsets of the set $\{a, b, c, d, e, f, g\}$ form two disjoint $S(7)$ :

$$
\begin{aligned}
\mathscr{S} & =\{\{a, b, c\},\{c, d, e\},\{e, f, a\},\{a, d, g\},\{b, e, g\},\{c, f, g\},\{b, d, f\}\} \\
\mathscr{S}^{\prime} & =\{\{a, b, e\},\{b, c, f\},\{c, d, a\},\{d, e, f\},\{f, g, a\},\{b, d, g\},\{c, e, g\}\}
\end{aligned}
$$

The same year (1850), Kirkman [12] proved that $D^{*}(9)=D(9)=7$. This result was "discovered" again by Sylvester ([18], [19]) in 1861, Walecki in 1883 (see Lucas [14, 161-197]), Bays [4] in 1917 and finally Emch [9] in 1929 (for more historical details, see Ahrens [1, 110-113]). The simplest description of 7 pairwise disjoint $S(9)$ on the set $\{a, b, c, d, e, f, g, h, i\}$ is given by the following square arrays

$$
\left.\begin{array}{cccccccccccc}
a & b & c & a & b & d & & d & e & g & g & h \\
d & a \\
d & e & f & & e & f & g & & h & i & a & b \\
c & h & i & & h & i & c & & b & c & f & \\
c & f & i \\
& & g & a & b & & a & d & e & & d & g
\end{array}\right) h
$$

The 12 lines of each system are simply the 3 rows, the 3 columns and the 6 products involved in the expansion of the "determinant" of each array.
The other values of $D^{*}(v)$ and $D(v)$ are unknown. Besides a few isolated lower bounds such as $D(13) \geqq 3, D(15) \geqq 2$ (Kirkman [13]), $D(31) \geqq 6$ (Assmus and Mattson ([2], [3])), the only known general results are $D^{*}\left(2^{n}-1\right) \geqq 2$ for every odd integer $n \geqq 3$ (Assmus and Mattson [2]) and $D^{*}(6 t+1) \geqq 2$ for every $t>0$ : indeed, as was shown by Rosa [16] and Di Paola [7], it is not difficult to construct two disjoint and isomorphic cyclic STS of order $6 t+1$ (an $S(v)$ is called cyclic if one of its automorphisms is a cycle of length $v$ ).
In 1917, Bays [4] conjectured that $D(v) \geqq(v-1) / 2$ for every $v \equiv 1$ or 3 $(\bmod 6), v>7$. Our first theorem shows that this conjecture is true for every $v \equiv 3(\bmod 6)$, even if $D(v)$ is replaced by $D^{*}(v)$.
2. A lower bound for $D^{*}(v)$.

Theorem 1. For every nonnegative integer $t$,

$$
D^{*}(6 t+3) \geqq 4 t+1 \quad \text { if } 2 t+1 \not \equiv 0(\bmod 3)
$$

and

$$
D^{*}(6 t+3) \geqq 4 t-1 \quad \text { if } 2 t+1 \equiv 0(\bmod 3)
$$

Proof. Let $G=\left\{1, a, a^{2}, \cdots, a^{2 t}\right\}$ be a multiplicative cyclic group of order $2 t+1$ and let us consider the Cartesian product $S=G \times\{0,1,2\}$. For every $e \in\{0,1,2\}$, the subset $G \times\{e\}$ of $S$ will be denoted by $G_{e}$ and any
element $(x, e)$ of $G_{e}$ by $(x)_{e}$ or, when there is no danger of confusion, simply by $x_{e}$.

The set $\mathscr{S}$ consisting of (i) all subsets $\left\{x_{0}, x_{1}, x_{2}\right\}$ of $S$ for any $x \in G$, (ii) all subsets $\left\{x_{0}, y_{0}, z_{1}\right\},\left\{x_{1}, y_{1}, z_{2}\right\},\left\{x_{2}, y_{2}, z_{0}\right\}$ of $S$ for any $x, y, z \in G$, where $x \neq y$ and $x y=z^{2}$, is easily verified to be an STS of order $6 t+3$; this construction is essentially due to Bose [5].
(a) Let $\varphi_{0}, \varphi_{1}, \cdots, \varphi_{2 t}$ be $2 t+1$ permutations of the set $S$ defined as follows: for every $x \in G$ and every $i=0,1, \cdots, 2 t$,

$$
\varphi_{i}\left(x_{0}\right)=x_{0}, \quad \varphi_{i}\left(x_{1}\right)=\left(a^{i} x\right)_{1}, \quad \varphi_{i}\left(x_{2}\right)=\left(a^{2 t-i} x\right)_{2} .
$$

Let $\mathscr{S}_{i}$ be the STS whose lines are the images of the lines of $\mathscr{S}$ by the permutation $\varphi_{i}$. The systems $\mathscr{S}_{0}, \mathscr{S}_{1}, \cdots, \mathscr{S}_{2 t}$ obtained in this way are clearly isomorphic; we are going to prove that they are also pairwise disjoint.
Let $\mathscr{S}_{i}, \mathscr{S}_{j}$ be any two of the above systems, with $i \neq j(i, j=0,1, \cdots$, $2 t$ ).

Any line of $\mathscr{S}_{i}$ having a point in $G_{0}, G_{1}$ and $G_{2}$ is of the form $\left\{x_{0}\right.$, $\left.\left(a^{i} x\right)_{1},\left(a^{2 t-i} x\right)_{2}\right\}$; in $\mathscr{S}_{j}$, such a line is $\left\{x_{0}^{\prime},\left(a^{j} x^{\prime}\right)_{1},\left(a^{2 t-j} x^{\prime}\right)_{2}\right\}$. If these lines coincide, we must have

$$
x=x^{\prime}, \quad a^{i} x=a^{j} x^{\prime}, \quad a^{2 t-i} x=a^{2 t-j} x^{\prime}
$$

which implies $a^{i}=a^{j}$, a contradiction since $i \neq j$.
Any line of $\mathscr{S}_{i}$ having two points in $G_{0}$ is of the form $\left\{x_{0}, y_{0},\left(a^{i} z\right)_{1}\right\}$ where $z^{2}=x y$; in $\mathscr{S}_{j}$, such a line is $\left\{x_{0}^{\prime}, y_{0}^{\prime},\left(a^{j} z^{\prime}\right)_{1}\right\}$ where $z^{\prime 2}=x^{\prime} y^{\prime}$. If they coincide, we have either

$$
\begin{aligned}
x & =x^{\prime}, & x & =y^{\prime}, \\
y & =y^{\prime}, & \text { or } & y
\end{aligned}=x^{\prime}, ~ a^{i} z=a^{j} z^{\prime} .
$$

As $G$ is abelian of odd order, we find in both cases $a^{i}=a^{j}$, a contradiction.
By similar straightforward computations, one can easily check that no line of $\mathscr{S}_{i}$ having two points in $G_{1}$ or $G_{2}$ can coincide with a line of $\mathscr{S}_{j}$ and therefore $\mathscr{S}_{i}$ and $\mathscr{S}_{j}$ are disjoint.
(b) Let $\sigma$ be the permutation of $S$ defined by $\sigma\left(x_{0}\right)=x_{2}, \sigma\left(x_{1}\right)=x_{1}$ and $\sigma\left(x_{2}\right)=x_{0}$ for every $x \in G$. Let $\mathscr{S}_{i}^{\prime}(i=0,1, \cdots, 2 t)$ be the STS whose lines are the images of the lines of $\mathscr{S}_{i}$ by the permutation $\sigma$. It is clear that $\mathscr{S}_{0}, \mathscr{S}_{1}, \cdots, \mathscr{S}_{2 t}, \mathscr{S}_{0}^{\prime}, \mathscr{S}_{1}^{\prime}, \cdots, \mathscr{S}_{2 t}^{\prime}$ are isomorphic and that $\mathscr{S}_{0}^{\prime}$, $\mathscr{S}_{1}^{\prime}, \cdots, \mathscr{S}_{2 t}^{\prime}$ are pairwise disjoint.

If a system $\mathscr{S}_{i}^{\prime}$ has a line in common with a system $\mathscr{S}_{j}$, this line must necessarily have a point in $G_{0}, G_{1}$ and $G_{2}$. In $\mathscr{S}_{j}$, any such line is of the form $\left\{x_{0},\left(a^{j} x\right)_{1},\left(a^{2 t-j} x\right)_{2}\right\}$; in $\mathscr{S}_{i}^{\prime}$, it is $\left\{\left(a^{2 t-i} x^{\prime}\right)_{0},\left(a^{i} x^{\prime}\right)_{1}, x_{2}^{\prime}\right\}$. If these
lines coincide, we have

$$
x=a^{2 t-i} x^{\prime}, \quad a^{j} x=a^{i} x^{\prime}, \quad a^{2 t-j} x=x^{\prime},
$$

which gives $a^{2 t-2 i+j}=1$ and $a^{1 t-i-j}=1$, that is $a^{3 i}=a^{6 t}$. Let us exclude the systems $\mathscr{S}_{i}^{\prime}$ which may have a line in common with one of the systems $\mathscr{S}_{0}$, $\mathscr{S}_{1}, \cdots, \mathscr{S}_{2 t}$. As the number of distinct cube roots of $a^{6 t}$ in the group $G$ is three or one according as the order of $G$ is or is not divisible by 3 , the number of excluded systems will be three or one, and the theorem follows immediately.

Corollary 1. $\quad D^{*}(v) \geqq 2$ for every $v \geqq 7, v \equiv 1$ or $3(\bmod 6)$.
This follows from Theorem 1 and from Rosa's result mentioned in the introduction.

Corollary 2. For every $v \geqq 7, v \equiv 1$ or $3(\bmod 6)$, there exists a balanced incomplete block design with parameters $v, k=3$ and $\lambda=2$, all of whose blocks are distinct (compare with Theorem 15.4.4 in Hall [10]).

Theorem 2. For every nonnegative integer $t$,

$$
D^{*}(6 t+1) \geqq t / 2 \quad \text { if } t \equiv 0(\bmod 2),
$$

and

$$
D^{*}(6 t+1) \geqq t \quad \text { if } t \not \equiv 0(\bmod 2) .
$$

Proof. Let $G=\left\{1, a, a^{2}, \cdots, a^{2 t-1}\right\}$ be a multiplicative cyclic group of order $2 t$ and let us consider the set $S=(G \times\{0,1,2\}) \cup\{\infty\}$ of cardinality $6 t+1$, where $\infty$ is a new symbol. For every $e \in\{0,1,2\}$, the element ( $x, e$ ) of the subset $G \times(e\}$ will be denoted by $(x)_{e}$ or, when there is no danger of confusion, by $x_{e}$. Finally, let $L=\left\{1, a, a^{2}, \cdots, a^{t-1}\right\}, R=\left\{a^{t}, a^{t+1}, \cdots\right.$, $\left.a^{2 t-1}\right\}$ and let $\mathscr{S}$ be the set consisting of
(i) all subsets $\left\{x_{0}, x_{1}, x_{2}\right\}$ of $S$ for any $x \in L$,
(ii) all subsets $\left\{\infty, x_{0},\left(a^{t} x\right)_{2}\right\},\left\{\infty, x_{1},\left(a^{t} x\right)_{0}\right\},\left\{\infty, x_{2},\left(a^{t} x\right)_{1}\right\}$ of $S$ for any $x \in L$,
(iii) all subsets $\left\{x_{0}, y_{0}, z_{1}\right\},\left\{x_{1}, y_{1}, z_{2}\right\},\left\{x_{2}, y_{2}, z_{0}\right\}$ of $S$ for any $x$, $y \in G$ with $x \neq y$ and
(1) $z \in L$ and $z^{2}=x y$ if $x y=a^{2 j}$,
(2) $z \in R$ and $a z^{2}=x y$ if $x y=a^{2 j+1}$.

It is not difficult to verify that $\mathscr{S}$ is an STS of order $6 t+1$; this construction is due to Skolem [17].

Let $\varphi_{0}, \varphi_{1}, \cdots, \varphi_{t-1}$ be $t$ permutations of the set $S$ defined as follows; for every $x \in G$ and every $i=0,1, \cdots, t-1$,

$$
\begin{array}{ll}
\varphi_{i}\left(x_{0}\right)=x_{0}, & \varphi_{i}\left(x_{1}\right)=\left(a^{i} x\right)_{1} \\
\varphi_{i}\left(x_{2}\right)=\left(a^{2 t-1-i} x\right)_{2}, & \text { and }
\end{array} \varphi_{i}(\infty)=\infty .
$$

Let $\mathscr{S}_{i}$ be the STS whose lines are the images of the lines of $\mathscr{S}$ by the permutation $\varphi_{i}$. The systems $\mathscr{S}_{0}, \mathscr{S}_{1}, \cdots, \mathscr{S}_{t-1}$ are clearly isomorphic. Moreover a proof similar to that of the preceding theorem shows that $\mathscr{S}_{0}, \mathscr{S}_{1}, \cdots, \mathscr{S}_{t / 2-1}$ are pairwise disjoint if $t$ is even and that $\mathscr{S}_{0}, \mathscr{S}_{1}$, $\cdots, \mathscr{S}_{t}$ are pairwise disjoint if $t$ is odd. The computations involved in this proof being quite straightforward, they will not be reproduced here.
3. A lower bound for $D(v)$. The two preceding theorems obviously give a lower bound for $D(v)$, since $D^{*}(v) \leqq D(v)$. We want to prove now that this lower bound is not best possible and can be improved in certain cases. For instance, Theorem 2 gives $D(19) \geqq 3$; our next result will show that $D(19) \geqq 9$.

Theorem 3. For every $v \geqq 7$ with $v \equiv 1$ or $3(\bmod 6)$,

$$
D(2 v+1) \geqq D(v)+2
$$

Proof. Let $D(v)=d$ and let $S, S^{\prime}$ be two disjoint sets of cardinality $v$. We shall denote by $\mathscr{S}_{1}, \mathscr{S}_{2}, \cdots, \mathscr{S}_{d} d$ pairwise disjoint STS of order $v$ on the set $S$, and by $\mathscr{S}_{d+1}^{\prime}, \mathscr{S}_{d+2}^{\prime}$ two disjoint STS of order $v$ on the set $S^{\prime}$ (the existence of at least two such systems follows from Corollary 1 and our hypothesis $v \geqq 7$ ).

Let $\alpha$ be any permutation of $S$ consisting of a single cycle of length $v$ and let $\varphi$ be any bijection from $S^{\prime}$ onto $S$. Finally let us consider the set $T=S \cup S^{\prime} \cup\{\infty\}$ of cardinality $2 v+1$, where $\infty$ is a new symbol.

We are going to construct $d+2$ Steiner triple systems $\mathscr{T}_{1}, \mathscr{T}_{2}, \cdots, \mathscr{T}_{d+2}$ on the set $T$. For every $i=1,2, \cdots, d$, the lines of $\mathscr{T}_{i}$ will be
(i) all lines of $\mathscr{S}_{i}$,
(ii) all subsets $\left\{\infty, x, \alpha^{i-1}(\varphi(x))\right\}$ of $T$, where $x$ is any point of $S^{\prime}$,
(iii) all subsets $\left\{x, y, \alpha^{i-1}(\varphi(z))\right\},\left\{x, \alpha^{i-1}(\varphi(y)), z\right\},\left\{\alpha^{i-1}(\varphi(x)), y, z\right\}$ of $T$, where $\{x, y, z\}$ is any line of $\mathscr{S}_{d+1}^{\prime}$.

For $i=d+1$ or $d+2$, the lines of $\mathscr{T}_{i}$ will be
(i) all lines of $\mathscr{S}_{i}^{\prime}$,
(ii) all subsets $\left\{\infty, x, \alpha^{i-1}(\varphi(x))\right\}$ of $T$, where $x$ is any point of $S^{\prime}$,
(iii) all subsets $\left\{x, \alpha^{i-1}(\varphi(y)), \alpha^{i-1}(\varphi(z))\right\},\left\{\alpha^{i-1}(\varphi(x)), y, \alpha^{i-1}(\varphi(z))\right\}$, $\left\{\alpha^{i-1}(\varphi(x)), \alpha^{i-1}(\varphi(y)), z\right\}$ of $T$, where $\{x, y, z\}$ is any line of $\mathscr{S}_{d+1}^{\prime}$.

It is easy to check that each $\mathscr{T}_{i}$ is an $S(2 v+1)$ and that $\mathscr{T}_{1}, \mathscr{T}_{2}, \cdots$, $\mathscr{T}_{d+2}$ are pairwise disjoint. This verification is rather tedious and will be omitted here.

Corollary 3. For every odd integer $t \geqq 1$,

$$
D(6 t+1) \geqq 2 t-1
$$

Proof. If $t=1$, the result is trivial. If $t=2 t^{\prime}+1 \geqq 3$, then $6 t+1=$ $2\left(6 t^{\prime}+3\right)+1$ and so, by Theorems 3 and 2 ,

$$
D(6 t+1) \geqq D\left(6 t^{\prime}+3\right)+2 \geqq 4 t^{\prime}+1=2 t-1
$$

4. Disjoint and isomorphic cyclic Steiner triple systems. Let us denote by $D_{c}^{*}(v)$ the maximum number of pairwise disjoint and isomorphic cyclic STS of order $v$. So for instance $D_{c}^{*}(1)=D_{c}^{*}(3)=1, D_{c}^{*}(7)=2$ and $D_{c}^{*}(9)=0$.

The following result is essentially due to Rosa [16].
Theorem 4. For every positive integer $t$,

$$
D_{c}^{*}(6 t+1) \geqq 2 .
$$

Proof. Peltesohn [15] has established the existence of a cyclic $S(v)$ for every $v \equiv 1$ or $3(\bmod 6)$, except $v=9$. Let $\mathscr{S}$ be a cyclic $S(6 t+1)$ constructed on the set $S=\{0,1, \cdots, 6 t\}$ in such a way that the permutation $\alpha=$ $(0,1, \cdots, 6 t)$ be an automorphism of $\mathscr{S}$. The distance $d_{i j}$ of the points $i$ and $j(i, j=0,1, \cdots, 6 t)$ will be defined as

$$
d_{i j}=\min \{|i-j|, 6 t+1-|i-j|\} .
$$

For every line $\{i, j, k\}$ of $\mathscr{S}$, the 3 distances $d_{i j}, d_{j k}, d_{k i}$ are distinct. Indeed, suppose for instance that $d_{i j}=d_{j k}$ and let $\alpha_{i j}$ be the power of $\alpha$ mapping $i$ onto $j$. As $d_{i j}=d_{j k}, \alpha_{i j}$ maps $j$ onto $k$ and therefore also $k$ onto $i$, otherwise the points $j$ and $k$ would belong to two distinct lines of $\mathscr{S}$. We conclude that $d_{i j}=d_{j k}=d_{k i}=(6 t+1) / 3$, which is clearly impossible.

Let $\mathscr{S}^{\prime}$ be the STS whose lines are the images of the lines of $\mathscr{S}$ by the involution $\sigma=(0)(1,6 t)(2,6 t-1) \cdots(i, 6 t+1-i) \cdots(3 t, 3 t+1)$. $\mathscr{S}^{\prime}$ is isomorphic to $\mathscr{S}$. Moreover $\mathscr{S}$ and $\mathscr{S}^{\prime}$ are disjoint. Indeed, let $\{i, j, k\}$ (resp. $\left\{i, j, k^{\prime}\right\}$ ) be the line of $\mathscr{S}$ (resp. $\mathscr{S}^{\prime}$ ) containing the points $i$ and $j$; it is easily seen that $d_{i k}=d_{j k^{\prime}}$. Therefore these two lines are distinct, otherwise $k=k^{\prime}$ and $d_{i k}=d_{j k}$, a contradiction.

Remark. If $\mathscr{S}$ is any cyclic $S(6 t+3)$ constructed on the set $S=\{0,1$, $\cdots, 6 t+2\}$ and admitting the permutation $\alpha=(0,1, \cdots, 6 t+2)$ as an automorphism, then $\mathscr{S}$ necessarily contains the lines $\{i, 2 t+1+i, 4 t+2+i\}$ for every $i=0, \cdots, 2 t$, and so $\mathscr{S}$ and its image $\mathscr{S}^{\prime}$ by the permutation $\sigma=(0)(1,6 t+2)(2,6 t+1) \cdots(3 t+1,3 t+2)$ are never disjoint.

Theorem 5. For every positive integer $t \not \equiv 1(\bmod 3)$,

$$
D_{c}^{*}(6 t+3) \geqq 4 t+1
$$

Proof. Let $\mathscr{S}$ be the $S(6 t+3)$ constructed in the proof of Theorem 1 . The permutations $\pi_{1}$ and $\pi_{2}$ of $S$ such that for every $x \in G$

$$
\begin{array}{ll}
\pi_{1}\left(x_{0}\right)=x_{1}, & \pi_{1}\left(x_{1}\right)=x_{2}, \\
\pi_{2}\left(x_{i}\right)=(a x)_{i} & \quad(i=0,1,2)
\end{array}
$$

are clearly two automorphisms of $\mathscr{S}$. Moreover if $2 t+1 \not \equiv 0(\bmod 3)$, the permutation $\pi_{1} \pi_{2}$ consists of a single cycle of length $6 t+3$ and $\mathscr{S}$ is a cyclic STS. The above inequality is then an immediate consequence of Theorem 1.
5. Open problems. (1) Given a Steiner triple system $\mathscr{S}$ of order $v \geqq 7$ on a set $S$ of cardinality $v$, is there always another Steiner triple system $\mathscr{S}^{\prime}$ isomorphic to $\mathscr{S}$ and disjoint from $\mathscr{S}$ ? In other words, is there always a permutation $\alpha$ of $S$ such that the image of any line of $\mathscr{S}$ by $\alpha$ is never a line of $\mathscr{S}$ ?
(2) Is it true that $D_{c}^{*}(6 t+3) \geqq 2$ for every $t \geqq 2$ ?
(3) The lower bounds for $D(v)$ given in this paper can certainly be improved. It is tempting to conjecture that $D(v)=v-2$ for every $v \geqq 9, v \equiv 1$ or $3(\bmod 6)$.
(4) Given an integer $n$ such that $0 \leqq n \leqq v(v-1) / 6$, let us denote by $D(v, n)$ the maximum number of STS of order $v$ that can be constructed on a set of cardinality $v$ in such a way that any two of them have exactly $n$ lines in common, these $n$ lines being moreover in each of the $D(v)$ systems. It is an easy exercise to check that $D(7,0)=D(7)=2, D(7,1)=3, D(7,2)=$ $0, D(7,3)=2, D(7,4)=D(7,5)=0, D(7,7)=\infty$. Kirkman [12] proved in 1850 that $D(15,5) \geqq 15$, but almost nothing is known in general about the function $D(v, n)$. For example, is it true that $D(v, 1) \geqq 2$ for every $v \geqq 3$, $v \equiv 1$ or $3(\bmod 6)$ ?
