Background: Identifying patients with atherosclerotic renal artery stenosis (ARAS) who will be improved in renal function after percutaneous transluminal renal artery stenting (PTRAS) is crucial since most patients show no worthwhile benefit of PTRAS. Although the assessment of renal parenchymal perfusion is useful for the identification, few studies predict the renal functional improvement by evaluating the characteristics of renal perfusion.

Objective: The aim of this study was to assess the renal parenchymal perfusion in ARAS patients with contrast-enhanced ultrasonography (CEUS) and predict the benefits of renal function after PTRAS utilizing time-intensity curve (TIC) parameters.

Methods: Thirty-eight kidneys in 30 ARAS patients received PTRAS in this study. They were divided into moderate stenosis group (n=25) and severe stenosis group (n=13) and mild dysfunction group (n=14) and moderate dysfunction group (n=24) according to the degree of renal stenosis and radioisotope glomerular filtration rate (rGFR). The baseline assessment of renal function and renal parenchymal perfusion were performed for all patients. rGFR was repeated to evaluate the renal outcome at 4 months after PTRAS. The outcome of PTRAS was classified as improved, stable, or deteriorated compared to the baseline. Time-intensity curve (TIC) parameters obtained from CEUS were analyzed to evaluate the predictive accuracy.

Results: TIC parameters (AUC and PI) were positively correlated with renal function ($r=0.617, 0.663; P<0.05$) but weakly and negatively correlated with the stenosis ($r=-0.360, -0.435; P<0.05$). Baseline rGFR was not accurate in predicting improved renal function after PTRAS (0.670). The accuracy of the combined prediction model of baseline AUC and PI (0.889) was higher than the individual indicators (baseline AUC: 0.855 and PI: 0.782).

Conclusion: CEUS could accurately assess renal parenchymal perfusion and identify ARAS patients with potential benefit after PTRAS. The combination of TIC parameters (AUC and PI) is valuable in the prediction of improved renal function after PTRAS.

Keywords: atherosclerotic renal artery stenosis, percutaneous transluminal renal artery stenting, renal parenchymal perfusion, contrast-enhanced ultrasonography, time-intensity curve, radioisotope glomerular filtration rate

Introduction

The prevalence of atherosclerotic renal artery stenosis (ARAS) is as high as 20% among people with diabetes and secondary hypertension.¹ ARAS may result in

renovascular hypertension and ischemic nephropathy, both of which are important causes of end-stage renal disease.² Percutaneous transluminal renal artery stenting (PTRAS) is becoming a preferred treatment for ARAS to correct renal hemodynamic disorders due to its advantages in trauma and safety.³ It is beneficial to the degrading of hypertension, improving renal function, or slowing down the deterioration of renal function. However, large-scale randomized controlled clinical trials such as ASTRAL and CORAL have shown no worthwhile benefit of PTRAS for patients with moderate to severe stenosis (stenosis of at least 60%).^{4,5} The outcome of renal function after revascularization is diverse.^{6,7} It is recognized that only about 20–30% of patients with moderate to severe ARAS show improved renal function after PTRAS.^{8,9} Therefore, identifying patients with improved outcome can help reduce inappropriate and potentially harmful interventions.^{10,11}

Because more than 50% of ARAS patients present renal cortical ischemia, the assessment of renal parenchymal perfusion is a useful supplement to evaluate the degree of renal ischemia, identify patients with potential benefits after PTRAS, and guide the treatment of ARAS.^{12,13} Cheung et al¹⁴ utilized MRI to identify kidneys with hibernating parenchyma and help predict the outcome of renal function after PTRAS. Compared with MRI, contrast-enhanced ultrasonography (CEUS) does not require the administration of a gadolinium-based contrast agent, and is capable of assessing the degree of ARAS and renal parenchymal perfusion simultaneously. The changes of CEUS parameters are not only earlier than laboratory indicators but also reveal the abnormal perfusion of renal parenchyma in the early stage.¹⁵ However, few studies on predicting the improvement of renal function after PTRAS by evaluating the characteristics of renal parenchymal perfusion in ARAS patients.

The purpose of this study was to assess the renal parenchymal perfusion of the affected kidney in ARAS patients and predict the benefits of renal function after PTRAS utilizing time-intensity curve (TIC) parameters.

Patients and Methods

Patient Recruitment

This prospective cohort study was approved by the ethics committee of Tongji Hospital of Tongji University (K-W-2019-008). Written informed consents were obtained from all participants prior to inclusion. This

study was conducted in accordance with the declaration of Helsinki.

Thirty-two patients with refractory hypertension combined with unexplained renal dysfunction and diagnosed with ARAS were screened for enrollment from Jun 2017 to May 2020. The definition of ARAS was: (1) at least one risk factor for atherosclerosis (diabetes, hyperlipidemia, age > 40 years, smoking);¹⁶ (2) at least 2 imaging findings suggesting atherosclerosis (cone-shaped renal artery stenosis or occlusion; eccentric stenosis; irregular plaque; calcification; stenosis involving the origin or proximal segment of the renal artery; imaging findings of atherosclerosis in other abdominal vessels).¹⁷

The inclusion criteria for enrolled patients were as follows: (1) age 40–75 years; (2) moderate to severe stenosis by CT angiography or digital subtraction angiography (moderate: 50%–69%; severe: 70%–99%); (3) systolic blood pressure of at least 180 mmHg and/or diastolic blood pressure of at least 110 mmHg without antihypertensive medications, or uncontrolled hypertension with 3 antihypertensive medications including diuretics; (4) diameter of at least 7.0 cm of the affected kidney. The exclusion criteria were as follows: (1) estimated glomerular filtration rate (eGFR) < 30 mL/(min·1.73 m²) [eGFR = 186 × serum creatinine (mg/dl)^{-1.154} × age^{-0.203} × 0.742 (if female) × 1.233 (if Chinese)];¹⁸ (2) patients with contraindications for renal revascularization; (3) patients with severe cardiovascular, cerebrovascular, and pulmonary diseases; (4) patients undergone previous revascularization for renal artery stenosis (5) patients with unclear ultrasound images or hypersensitivity to ultrasound contrast agents.

There were 26 patients with unilateral renal artery stenosis and 6 patients with bilateral renal artery stenosis. Hence, 38 kidneys needed to be revascularized in this study. According to the degree of renal artery stenosis, 38 kidneys were divided into moderate stenosis group (n=25) and severe stenosis group (n=13). Besides, 30 patients with clinical suspicion of an atherosclerotic renovascular disease but without evidence of ARAS and renal dysfunction were enrolled as the control group. The demographic and clinical characteristics of all subjects including age, gender, history of smoking, course of hypertension, type of antihypertensives, diabetes, hyperlipidemia, heart rate, body mass index (BMI), systolic pressure, diastolic pressure, serum creatinine (Scr), and eGFR were recorded.

Assessment of radioisotope glomerular filtration rate (rGFR)

All patients underwent baseline assessment of renal function using Philips Precedence SPECT/CT camera (Philips Healthcare, Guildford, United Kingdom). The assessments were performed by 2 radiologists with more than 10 years' experience in SPECT. After accurately measuring the height and weight of each patient, a bolus injection of ^{99m}Tc -DTPA 185MBp was performed. Renal dynamic blood flow and functional imaging were conducted within 20–30 minutes. rGFR of each kidney was measured by the Gate's method.¹⁹ According to the rGFR, 38 kidneys were divided into mild dysfunction group ($35 \text{ mL/min} > \text{rGFR} \geq 25 \text{ mL/min}$, $n=14$) and moderate dysfunction group ($25 \text{ mL/min} > \text{rGFR} \geq 15 \text{ mL/min}$, $n=24$). At 4 months after renal revascularization, rGFR was repeated to evaluate the outcome of renal function. The outcome was classified as improved, stable, or deteriorated according to the following thresholds compared to the baseline (improved: rGFR increased by $> 15\%$; deteriorated: rGFR decreased by $> 15\%$; stable: changes between the improved and deteriorated).

Renal Parenchymal Perfusion by CEUS

The renal parenchymal perfusion was performed using a MyLab Twice ultrasound system (Esaote, Genova, Italy) by 2 sonographers with more than 10 years' experience in ultrasound. The ultrasound was oriented at the largest section of kidneys with the patient in the lateral decubitus position. CEUS was performed after the injection of

1.2 mL of the ultrasound contrast agent (SonoVue, Bracco, Italy) followed by 5 mL flush of 0.9% sodium chloride solution. The sonographer continuously observed the contrast process of the renal parenchyma in real-time for 3 min until the enhancement intensity was weakened to near the pre-test level. TIC quantitative analysis began to run after two regions of interest (ROI) on each image (reference ROI and analysis ROI) were set (Figure 1). The CEUS quantitative data, including rise time (RT), peak intensity (PI), time to peak (TTP), mean transit time (mTT), and area under the curve (AUC) were obtained. In order to reduce bias, the analysis was repeated twice to calculate the average value.

Statistical Analysis

Statistical analyses were performed using statistical product and service solutions (version 22.0; SPSS Inc., Chicago, IL, USA) and MedCalc (Version 22.0.1; MedCalc Software, Ostend, Belgium). The numerical data were expressed as mean \pm standard deviations for normally distributed variables and as median (interquartile range) for non-normally distributed variables. Independent sample *t*-test, paired-samples *t*-test, one-way ANOVA and a post hoc Student-Newman-Keuls test, and Mann–Whitney *U*-test were used for comparison. The categorical variables were expressed as number (percentage) and the comparison was performed by the chi-square test. The correlations of CEUS parameters with renal artery stenosis and rGFR were analyzed with Pearson

A

B

Figure 1 Representative TIC (A) and schematic diagram (B) of renal parenchymal perfusion. The CEUS quantitative data were derived from the TIC, including RT, PI, TTP, mTT, and AUC.

correlations. Receiver-operating characteristic (ROC) curve was established and the area under the ROC curve was used to evaluate the predictive accuracy for the renal functional outcome after PTRAS, and a multi-indicator combined prediction model was established with Logistic regression.

Results

Demographic and Clinical Characteristics of All Subjects

The demographic and clinical characteristics of all subjects are shown in Table 1. ARAS patients had lower eGFR and higher Scr compared with the control patients. No differences in other characteristics were observed ($P > 0.05$).

Renal Parenchymal Perfusion in Different Degrees of Renal Artery Stenosis

None of the subjects had adverse reactions to contrast medium. Figure 2 shows the typical TIC features in control, moderate stenosis, and severe stenosis groups. Each curve clearly showed ascending slope, peak, and descending slope. The TIC of the control group showed a steep ascending slope, and then gradually descended to the baseline level. Among the three groups, the largest AUC and PI were present in the control group, and the AUC and PI of the moderate stenosis group were slightly larger than that of the severe stenosis group. Quantitative analysis of the TIC parameters (Table 2) showed that the AUC and PI of the moderate and severe stenosis groups were smaller than the control group ($P < 0.05$). There is no difference in all TIC parameters between the moderate and severe stenosis groups ($P > 0.05$).

Renal Parenchymal Perfusion in Different Degrees of Renal Dysfunction

The typical TIC features in mild and moderate dysfunction groups are shown in Figure 3. Compared with the control group, the AUC and PI of the mild and moderate dysfunction groups were smaller, and the changes of AUC and PI became more obvious as the renal dysfunction worsened. The quantitative analysis of the TIC parameters in different degrees of renal dysfunction is shown in Table 3. The AUC and PI of the mild and moderate dysfunction groups were smaller than the control group ($P < 0.05$), and the AUC and PI of the moderate dysfunction group were smaller compared with the mild dysfunction group ($P < 0.05$).

Correlation of TIC Parameters (AUC and PI) with Renal Artery Stenosis and Renal Function

Correlation analysis showed that the TIC parameters (AUC and PI) were positively correlated with renal function ($r=0.617, 0.663; P<0.05$), but weakly and negatively correlated with the stenosis ($r=-0.360, -0.435; P<0.05$) (Figure 4). rGFR and renal artery stenosis also showed a weak negative correlation ($r=-0.423; P<0.05$).

Outcome of Blood Pressure and Renal Function After PTRAS

All operations were successfully completed and a total of 38 renal artery stents were implanted. The postoperative systolic pressure was lower than that before operation, and the difference was statistically significant (preoperative

Table 1 Demographic and Clinical Characteristics of ARAS and Control Patients

eGFR[mL/(min·1.73m ²)]	58.41±8.82	106.93±8.63	<0.001*

Notes: *For independent sample t-test, [§]for chi-square test, [#]for Mann-Whitney U-test.

Abbreviations: ARAS, atherosclerotic renal artery stenosis; BMI, body mass index; Scr, serum creatinine; eGFR, estimated glomerular filtration rate.

Figure 2 Changes of TIC schematic diagrams in different degrees of renal arterial stenosis (A–C). The largest AUC and PI were present in the control group (A), and the AUC and PI of the moderate stenosis group (B) were slightly larger than those of the severe stenosis group (C). Other parameters (RT, TTP, and mTT) are similar among the three groups.

Abbreviations: TIC, time-intensity curve; CEUS, contrast-enhanced ultrasonography; AUC, area under the curve; RT, rise time; PI, peak intensity; TTP, time to peak; mTT, mean transit time.

systolic pressure: 150.63 ± 13.10 mmHg vs postoperative systolic pressure: 138.29 ± 8.23 mmHg, $P < 0.001$; preoperative diastolic pressure: 79.88 ± 9.41 mmHg vs postoperative diastolic pressure: 74.26 ± 7.25 mmHg, $P > 0.05$, paired-samples t -test). The types of antihypertensive agents declined significantly compared preoperatively (3 (2,4) vs 2 (1, 2), $P < 0.001$, Mann–Whitney U -test). The postoperative eGFR [63.27 ± 7.23 mL/(min \cdot 1.73m 2)] was higher than the baseline [58.41 ± 8.82 mL/(min \cdot 1.73m 2)], but the difference was not statistically significant ($P > 0.05$, paired-samples t -test). The average change in rGFR of 38 stented kidneys from baseline to 4 months after surgery was 1.26 ± 11.36 mL/min. Ten kidneys (26.3%) improved [changes of rGFR: 5.5 (4.5, 7.0) mL/min], 22 kidneys (57.9%) remained stable [1.5 (–2.5, 2.0) mL/min], and 6 kidneys (15.8%) deteriorated [–5.0 (–4.5, –6.5) mL/min] after surgery.

Predictive Accuracy for the Renal Functional Outcome After PTRAS

The accuracy of baseline rGFR was 0.670 in predicting improved renal function following PTRAS. Compared

with the baseline rGFR, the accuracy of baseline AUC (0.855) and PI (0.782) were higher ($P < 0.05$). The combination of PI, AUC and rGFR was not accurate (0.807) due to the influence of rGFR. Hence, the accuracy of the combined prediction model only included baseline AUC and PI (0.889) was the highest, with a sensitivity and specificity of 100% and 75%, respectively (Figure 5). The fitting equation was $\text{Logit}(P) = 14.861 - 0.011 \cdot \text{baseline AUC} - 0.197 \cdot \text{baseline PI}$.

Discussion

The present study revealed that renal parenchymal perfusion was closely associated with the renal function of the affected kidney but weakly associated with the renal artery stenosis in ARAS patients. TIC parameters (AUC and PI) were useful in the assessment of renal parenchymal perfusion in different degrees of renal dysfunction. ROC analyses indicated that compared with baseline rGFR, baseline AUC and PI were helpful and sensitive for the prediction of improved renal function following PTRAS. Their combination was more accurate than the individual indicators and could be useful for identifying patients with potential benefits after PTRAS.

Table 2 Comparison of TIC Parameters Among the Moderate and Severe Stenosis Group and the Control Group

Group	Number of Kidneys	Stenosis (%)	AUC (dB s)	RT (s)	PI (dB)	TTP (s)	mTT (s)
Control group	30	21.46 ± 7.35	1594.29 ± 294.84	20.93 ± 3.96	22.03 ± 4.28	10.83 ± 4.92	42.94 ± 8.94

Although PTRAS can effectively reduce blood pressure and improve ischemic renal function, clinical trial data do not support that renal revascularization is more beneficial to patients than drug therapy.^{4,5} Our study indicated that only 26.3% of kidneys with renal artery stenosis obtained improved renal function after PTRAS, which is in line with the study of Chrysochou et al²⁰ that has reported on renal functional response. Weinberg et al²¹ believe that defects in the selection of indications may be an important reason for the inaccurate results of clinical trials. SCAI expert consensus statement further regulates the surgical indications of PTRAS, among which ischemic nephropathy with progressive renal function decline is one of the main indications.²²

Since the compensation of contralateral kidney, the Scr or eGFR in patients with unilateral renal artery stenosis is often in the normal range. Therefore, objective and accurate evaluations are needed to assess the renal ischemia caused by renal artery stenosis. The rGFR of affected kidneys can indicate decreased renal function, but the degree of renal artery stenosis and decreased renal

function are not matched.²³ In our study, the baseline rGFR of the affected kidney was weakly correlated with the stenosis. Dong et al²⁴ also found that there was no significant correlation between the changes in GFR and the degree of renal artery stenosis. Moreover, many factors affect the changes in GFR (such as hypertension, nephritis or nephropathy, etc.), which cannot fully indicate the outcome of renal function after PTRAS. It is recognized that renal parenchymal blood flow accounts for about 90% of the entire kidney blood flow. The measurement of renal parenchymal perfusion utilizing CEUS can evaluate the blood supply of the entire kidney, thereby assessing renal dysfunction caused by renal artery stenosis. Our study found that the TIC parameters (AUC and PI) of CEUS was closely associated with the renal function of affected kidneys, which indicated that they were useful in the assessment of renal parenchymal perfusion in different degrees of renal dysfunction.

In this study, after 4 months of PTRAS, the blood pressure of ARAS patients was lower than the baseline, which is consistent with the results of previous studies.²⁵

Table 3 Comparison of TIC Parameters Between the Mild and Moderate Dysfunction Group and the Control Group

Group	Number of Kidneys	rGFR (mL/min)	AUC (dB s)	RT (s)	PI (dB)	TTP (s)	MTT (s)
Control group	30	61.0 (58.0, 63.0)	1594.29±294.84	20.93±3.96	22.03±4.28	10.83±4.92	42.94±8.94
Mild dysfunction group	24	29.0 (27.0, 30.0)	1322.33±212.38 ^a	19.26±3.63	20.79±3.71 ^a	11.39±4.15	44.39±8.21
Moderate dysfunction group	14	22.5 (21.0, 23.0)	1119.00±171.61 ^{ab}	18.63±3.26	15.29±3.12 ^{ab}	12.62±4.73	46.37±9.62
F			13.168	0.365	23.824	0.313	0.844
P			<0.001	0.782	<0.001	0.817	0.478

Notes: ^aP < 0.05 (compared with the control group), ^bP < 0.05 (compared with the moderate stenosis group).

Abbreviations: TIC, time-intensity curve; AUC, area under the curve; RT, rise time; PI, peak intensity; TTP, time to peak; mTT, mean transit time.

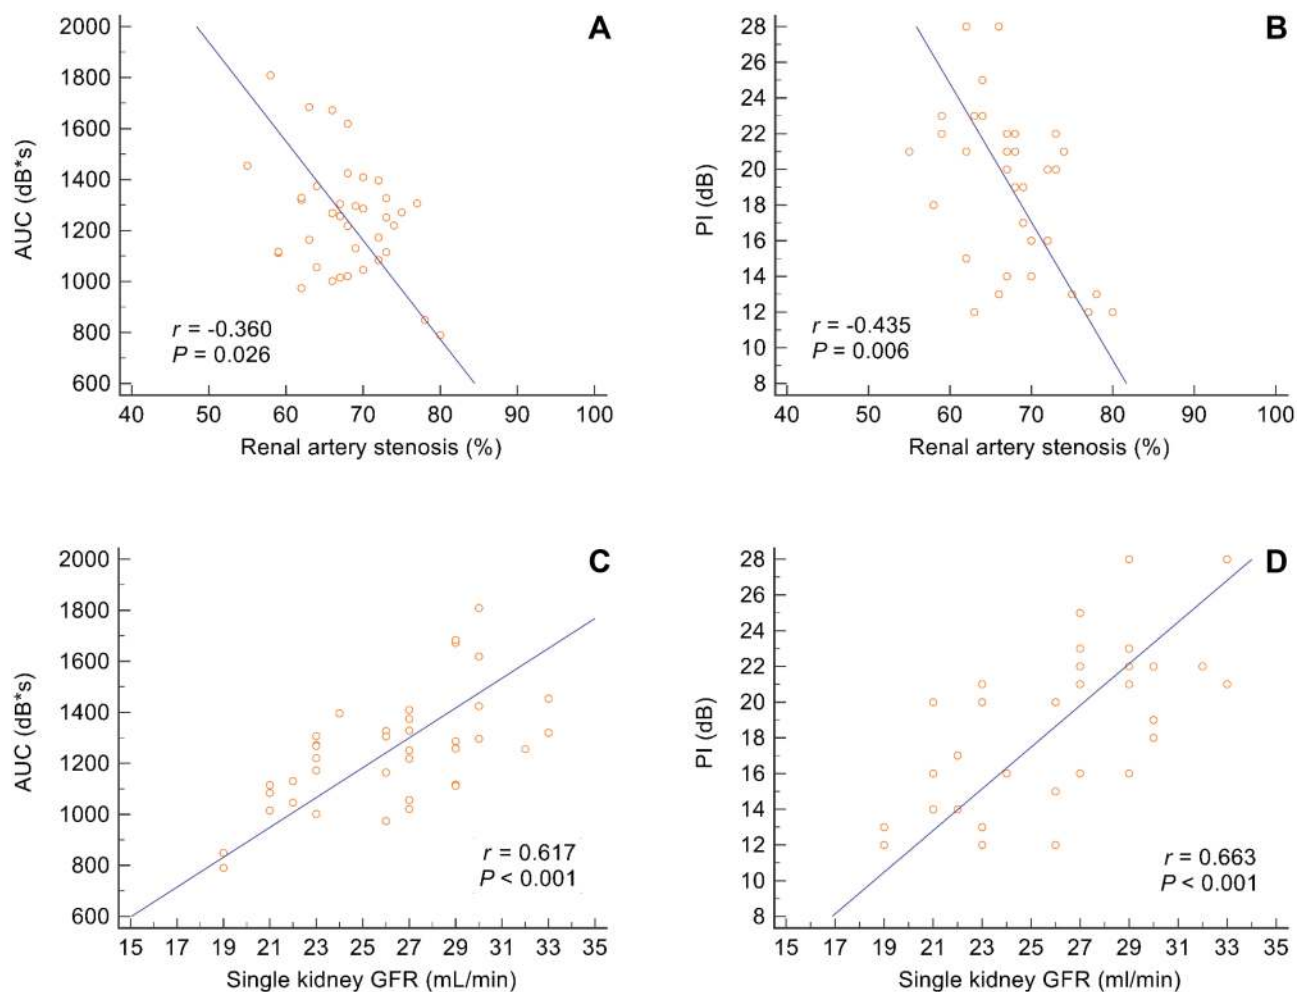

Figure 4 Correlation analysis of TIC parameters (AUC and PI) with different degrees of renal artery stenosis and rGFR. (A) and (B) shows the association between TIC parameters and renal artery stenosis. (C) and (D) shows the association between TIC parameters and rGFR of affected kidneys.

Abbreviations: TIC, time-intensity curve; AUC, area under the curve; PI, peak intensity.

The rGFR of 10 kidneys was improved compared with the baseline, which indicated restored renal blood flow and improved renal function. However, there were 22 kidneys remained stable and 6 kidneys deteriorated. It implied that the outcome of PTRAS depended on different degrees of preoperative renal ischemia.

One hypothesis to explain these differences may be that there is “hibernating parenchyma” in those kidneys with improved outcomes after PTRAS.^{20,26} The “hibernating parenchyma” means that after the compensating capacity of the kidney gradually decreases, part of the glomerular function will be in a dormant state to maintain the blood supply of the medulla. The renal microvasculature remodeling and damage may temporarily or permanently deteriorate renal blood flow, glomerular filtration capacity and renal tubular function, which may be the starting point of RAS.^{27–29} Since no irreversible

structural changes have occurred, the return of blood flow to the ischaemic tissue after the stenosis corrected can help improve renal function. Onuigbo et al³⁰ also reported that in patients with hemodynamically significant renal artery stenosis who present with acutely worsening renal failure, PTRAS was more likely than not to produce both renal and cardiovascular benefits. The ROC curves in this study revealed that the TIC parameters (AUC and PI) could help identify the kidneys with “hibernating parenchyma” in ARAS patients which were still salvageable with PTRAS. The combined model based on baseline AUC and PI was more accurate in the prediction of renal functional improvement than the individual indicators. In the clinical setting, physicians can calculate the probability of improved outcome using the combined model and perform the subsequent treatment.

Figure 5 ROC curves of baseline rGFR, AUC, PI, the combination of baseline AUC and PI, and the combination of PI, AUC and rGFR in predicting improved renal function following PTRAS. Blue line represents the combination of AUC and PI (0.889). Green line represents the combination of PI, AUC and rGFR (0.807). Orange line represents baseline AUC (0.855). Green dashed line represents baseline PI (0.782). Pink dashed line represents baseline rGFR (0.670).

Abbreviations: ROC, receiver-operating characteristics; AUC, area under the curve; PI, peak intensity; rGFR, radioisotope glomerular filtration rate; PTRAS, percutaneous transluminal renal artery stenting.

The primary limitation of this study is the limited patient numbers. This leads to a lack of kidneys with irreversible structural changes in our study. Although in theory, PTRAS may not be beneficial to restore the renal function of this type of kidney, it still needs to be verified by increasing cases. Although CEUS provided us with a safe method to evaluate renal perfusion, it still faces the limitation of measurement errors caused by factors such as obesity and poor breathing coordination. It is particularly obvious in the diagnosis of renal artery stenosis due to the attenuation of acoustic energy and the limitation of angle adjustment. Besides, we did not evaluate whether renal functional improvement after PTRAS translated into a survival benefit. Nonetheless, the results of this study do inform us that renal parenchymal TIC has potential clinical uses in the future.

In conclusion, the TIC parameters (AUC and PI) were closely associated with the renal function in ARAS patients. Their combination is valuable in the prediction of renal functional improvement after PTRAS. Our study strongly demonstrated that CEUS could accurately assess renal parenchymal perfusion and identify ARAS patients with potential benefit after PTRAS.

The International Journal of General Medicine is an international, peer-reviewed open-access journal that focuses on general and internal medicine, pathogenesis, epidemiology, diagnosis, monitoring and treatment protocols. The journal is characterized by the rapid reporting of reviews, original research and clinical studies

across all disease areas. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
