#### Abstract

We present an $O\left(n \cdot d^{O(1)}\right)$ algorithm to compute the convex hull of a curved object bounded by $O(n)$ algebraic curve segments of maximum degree $d$.

## 1. Introduction

The convex hull computation is a fundamental one in computational geometry. Several linear-time algorithms for computing the convex hull of simple planar polygons are known, McCallum and Avis (1979), Graham and Yao (1983), D.T. Lee (1983), Bhattacharya and El Gindy (1984). These algorithms achieve the more efficient $O(n)$ bound whereas the $\Omega(n \log n)$ lower bound applies to general problem of computing the convex hull of $n$ points in the plame, see Preparata and Shamos (1985). The above algorithms for planar polygons are all vertex-based and it is not straighforward to modify them to deal with curved planar objects with piecewise algebraic boundary curves. Figure 1.1 shows a difference between simple polygons and curved objects, where a single edge may intersect two different pockets. By generalizing Graham and Yao (1983) to an edge-based algorithm Schaffer and Van Wyt (1987) extended these results to a linear-time algorithm for curved objects bounded by piecewise-smooth Jordan curves. Even though this algorithm gives an $O\left(n \cdot d^{O(1)}\right)$ bound for high order boundary curves with maximal degree $d$, the practical efficiency is limited to lower degree algebraic curves because of the ubiquitous computation of common tangents of two curved edges. To improve the practical efficiency for high degree algebraic boundary curves, it is necessary to reduce the time consuming curved edge operations. As we will see in §3, the common tangent computation is the most expensive edge operation for both rational and nonracional curves. The philosophy of designing our algorithm is to reduce the number of common tangent computations by detecting only those edges with right orientations. By generalizing the method of D.T. Lee (1983) to a coordinate-based algorithm we suggest an $O\left(n \cdot d^{O(1)}\right)$ time algorithm to compute the convex hull of objects bounded by algebraic curve segments (possibly non-smooth) with maximum degree $d$, which form a Jordan boundary curve. To simplify the whole design of algorithm and improve the overall efficiency we segment each boundary curved edge into monotone subsegments in a preprocessing step. Though an expensive computation, $O\left(d^{3} \cdot \log d\right)\left(r e s p . ~ O\left(d^{6} \cdot \log d+T(d)\right)\right.$ time for rational (resp. nonrational) curves on an arithmetic operation model, it greatly simplifies further operations on boundary curve segments, where $T(d)$ is the time required for the curve segment tracing. Our algorithm computes the convex hull in a single pass using a single stack and subdivides the original problem into four subproblems. The convex hull computation by Schaffer and Van Wyk (1987) requires two passes and subdivides the original problem into two subproblems. Souvaine (1986) also suggests a convex hull computation algorithm based on bounding polygon approach for a class of curved objects (termed splinegons). Figure 1.1 also shows a difference between our algorithm and other algorithms for the curved case. Both Souvaine (1986) and Schaffer and Van Wyk (1987) consider the edge $C_{j}$ as an event edge and apply the timeconsuming common tangent operation for such edges. Since edges with such orientation cannot belong to
$\ddagger$ Research supported in part by NSF grants MIP-85 21356, CCR-8619817 and a David Ross Fellowship.
the convex hull boundary, these edges are ignored and not considered as event edges in our algorithm. Half-plane containments and/or line-curve segment intersections are sufficient to detect edges with wrong orientations, which cost less than common tangent computations. Further, our algorithm maintains a very simple loop invariant, see the property (*) in $\S 4.1$, which makes the design of a simple algorithm easier.

The rest of the paper is as follows. In $\S 2$ we describe the boundary representation for a planar geometric model with algebraic boundary curves. In $\$ 3.1$ we segment each boundary curved edge into monotone subsegments as a preprocessing step. Crucial too is the internal representation of algebraic curves, i.e., whether they are paramerrically or implicitly defined. All algebraic plane curves are implicily defined by a single polynomial equation $f(x, y)=0$. A subclass of algebraic curves known as rational curves, have an altemate representation in terms of rational functions, $x=f(t) / h(t)$ and $y=g(t) / h(t)$, with $f, g, h$ being polynomials in $t$. We present algorithms for both these internal representations. In $\S 4$ we present an $O\left(n \cdot\left(d^{8} \log d+d^{2} T(d)\right)\right.$ ) (resp. $O\left(n \cdot\left(d^{26} \log d+d^{2} T(d)\right)\right)$ algorithm to compute the convex hull of the geometric models of $\$ 2$ which have all boundary curves as rational (resp. non-rational). Here $T(d)$ is the worst case time taken to trace an algebraic curve segment of degree $d$, see Bajaj, Hoffmann and Hopcroft (1986). The worst case timing analysis in computing the exponent of the $d^{\circ(1)}$ is for the general implicitly defined algebraic curves. This exponent is considerably less for curves in their parametric representation. Our model of computation is the arithmetic model where arithmetic operations have unit time cost, see Aho, Hopcroft, and Ullman (1974).

## 2. Algebraic Boundary Geometric Model

In a general boundary representation, an object with algebraic boundary curves consists of the following:
(1) A face bounded by a single oriented cycle of edges which forms a Jordan curve. (i.e, nonintersecting)
(2) A finite set of directed edges, where each edge is incident to two verices. Each edge also has a curve equation, represented implicitly and when possible also with parameric equarion. Further an interior point is also provided on each edge which helps remove any geometric ambiguity in the representalion for high degree algebraic curves, Requicha (1980).
(3) A finite set of vertices usually specified by Cartesian coordinates.

The curve equation for each edge is chosen such that the direction of the normal at each point of the edge is towards the exterior of the object For a simple point on the curve the nomal is defined as the vector of partials to the curve evaluated at that point. For a singular point on the curve we associate a range of normal directions determined by normals to the tangents at the singular point Further the edges are oriented such that the interior of the object is to the left when the cycle of edges is traversed. Straightorward assumptions are also made, e.g. object has no holes; edges may be singular, however loop-free; different edges do not intersect except at vertices etc.

## 3. Computations with Algebraic Curves

In this section we consider some primitive geomerric operations to manipulate algebraic curve segments. Prior work, of relevance to later sections here, have considered the generation of rational parametric equations for implicity defined rational algebraic plane curves and surfaces, see Abhyankar and Bajaj (1987a, b, c), the generation of implicit equations for parametrically defined algebraic curves and surfaces, see Bajaj (1987), as well as the robust tracing of algebraic curve segments with the correct connectivity, especially when tracing through complicated singularities, see Bajaj, Hoffmann and Hopcroft (1986). The latter for instance is very useful in determining when a given point lies within a cenain
implicitly defined algebraic curve segment In $\S 3.1$ we consider how to segment the boundary curve segments into monotone pieces, and in $\S 3.2$ we consider operations to compute curve-line segments intersection, halfplane containments, and common supporting lines.

### 3.1. Monotone Segmentation

In many of the computational geometry problems dealing with curved objects, it is very convenient to design efficient algorihms when we assume each curve segment is monotone (i.e. monotone in $x$ and $y$ coordinates and without any singuiar or inflection point). We thus first consider how to achieve this monotone segmentation, as a preprocessing step, for a general algebraic curve. This monotone segmentation requires adding singular points, infection points and extreme points on the curve as extra vertices.

First we take care of singular points on curved edges. Singularities are delermined for each curved edge and are computed by using Lemma 3.1.1: I (i) and II (i). The boundary of the object is next modified such that nonsingular edges are either convex, concave or linear segments. Such conditions are easily met by adding extra vertices to inflection points of curved edges. Inflection points of curves can be obtained and the edges are marked convex, concave or linear respectively by using Lemma 3.1.1: I (iv), (v), (vi) and II (iv), (v), (vi). We may also assume edges are further segmented so that extreme points along $x$ or $y$ directions added as vertices. These extreme points are computed by using Lemma 3.1.1: I (ii), (iii) and II (ii), (iii).

Definition 3.1 : Let $C$ be a directed boundary edge without any inflection or singular point. Then
(1) $C$ is convex if and only if the gradient of $C$ turns counter-clockwise along $C$
(2) $C$ is concave if and only if the gradient of $C$ turns clockwise along $C$
(3) $C$ is monotone if and only if $C$ is either convex, concave or linear, and the interior of $C$ doesn't include any extreme point along the $x$ or $y$ directions.
Lemma 3.1.1: (I) Let $C:(a, b) \rightarrow R^{2}$ be a curve parametrized by $t \in(a, b)$ and $p=C(t)=$ $\left(c_{1}(t), c_{2}(t)\right)$ be a point on this curve. Then
(i) $p$ is a (non-self-intersecting) singular point if and only if $c^{\prime}(t)=c_{2}^{\prime}(t)=0$,
(ii) $p$ is a non-singular $x$-extreme point if and only if $c_{2}^{\prime}(t)=0$ and $c_{1}^{\prime}(t) \neq 0$,
(iii) $p$ is a non-singular $y$-extreme point if and only if $c_{1}^{\prime}(t)=0$ and $c_{2}^{\prime}(t) \neq 0$, and
(iv) $p$ is an inflection point of the curve $C$ if and only if $\kappa(p)=0=c^{\prime}{ }_{1}(t) \cdot c^{\prime \prime}{ }_{2}(t)-c^{\prime}(t) \cdot c^{\prime \prime}{ }_{1}(t)$.

If $C$ has no inflection point, then
(v) $C$ is convex if and only if $c^{\prime}{ }_{1}(t) \cdot c^{\prime \prime}{ }_{2}(t)-c^{\prime}{ }_{2}(t) \cdot c^{\prime \prime}{ }_{1}(t)>0$, and
(vi) $C$ is concave if and only if $c_{1}^{\prime}(t) \cdot c^{\prime \prime}(t)-c_{2}^{\prime}(t) \cdot c^{\prime \prime}(t)<0$.
(II) Let $C$ be a curve impliciliy defined by $f(x, y)=0$ and $p=(x, y)$ be a point on the curve $C$. Then
(i) $p$ is a singular point if and only if $f=f_{x}=f_{y}=0$,
(ii) $p$ is a non-singular $x$-extreme point if and only if $f=f_{y}=0$ and $f_{x} \neq 0$,
(iii) $p$ is a $y$-extreme point if and only if $f=f_{x}=0$ and $f_{y} \neq 0$, and
(iv) $p$ is an inflection point if and only if $f_{x I} \cdot\left(f_{y}\right)^{2}-2 f_{2 y} \cdot\left(f_{x} \cdot f_{y}\right)+f_{y y} \cdot\left(f_{x}\right)^{2}=0$.

If $C$ has no inflection point, then
(v) $C$ is convex if and only if $f_{z x} \cdot\left(f_{y}\right)^{2}-2 f_{x y} \cdot\left(f_{x} \cdot f_{y}\right)+f_{y y} \cdot\left(f_{x}\right)^{2}>0$, and
(vi) $C$ is concove if and only if $f_{x x} \cdot\left(f_{y}\right)^{2}-2 f_{x y} \cdot\left(f_{x} \cdot f_{y}\right)+f_{y y} \cdot\left(f_{x}\right)^{2}<0$.

Proof : Most of these results are classical, see for example Walker (1978).
Lemma 3.12 : (I) For a paramerric curve segment $C$ of degree $d$, a monotone segmentation can be obtained in $O\left(d^{3} \cdot \log d\right)$ time in the worst case and in $O\left(d^{2} \cdot \log ^{2} d\right)$ time on the average.
(II) For an implicit algebraic curve segment $C$ of degree $d$, a monotone segmentation can be
obtained in $O\left(d^{6} \cdot \log d+T(d)\right)$ time in the worst case and in $O\left(d^{4} \cdot \log ^{2} d+T(d)\right)$ time on the average, where $T(d)$ is the time required for the curve segment tracing.
Proof: (1) The above equations are of degree $O(d)$ in a single variable $t$, and the squarefree parts can be calculated in $O\left(d \log ^{2} d\right)$ time and be solved using root isolations in $O\left(d^{3} \log d\right)$ time in the worst case and in $O\left(d^{2} \cdot \log ^{2} d\right)$ time on the average, see Schwartz and Sharir (1983).
(2) The above equations are two simultaneous polynomial equations of degree $O(d)$ in two variables $x$ and $y$. We can eliminate one variable (say, y) using the Sylvester resultant in $O\left(d^{4} \log ^{3} d\right)$ time, see Collins (1971), Bajaj and Royappa (1987), and solve the resuling equation of degree $O\left(d^{2}\right)$ in one variable (say, $x)$ in $O\left(d^{6} \log d\right)$ time in the worst case and $O\left(d^{4} \log ^{2} d\right)$ time on the average. Similarly, we can solve for another variable (say, $y$ ) with the same time complexity. Finally, the solution points on the curve segment $C$ can be found by tracing the curve segment in $T(d)$ time.

### 3.2. Basic Operations on Monotone Curve Segments

In this section, we consider four types of primitive operations on the monotone curve segments. As we will see in $\$ 4$, these are all the required geometric operations on the monotone curve segments to compute the convex hull of planar curved object once the boundary curves are segmented into monotone pieces. All the other operations are based on the coordinates of the verices of the monotone curve segments. These primitive operations compute:
(A) The intersection(s) of a monotone curve segment $C$ and a line segment $L$
(B) The containment of a monotone curve segment $C$ in the upper-left halfplane $H^{U L}(L)$ of a line $L$
(C) The common supporting line $L$ of a monotone curve segment $C$ and a point $q$ such that $C \cup\{q\}$ $\subset H^{U L}(L)$, and the corresponding supporting point $p$ of $L$ at $C$
(D) The common supporting line $L$ of two monotone curve segments $C$ and $D$ such that $C \cup D \subset$ $H^{U L}(L)$, and the corresponding supporting points $p$ and $q$ of $L$ at $C$ and $D$ respectively.

## Line-Curve Segments Intersection

Suppose $C$ is a monotone curve segment and $L$ is a line segment. Let $R(C)$ and $R(L)$ be the minimal rectangles with sides parallel to coordinate axes and containing $C$ and $L$ respectively, and $T(C)$ be the minimal triangle defined by the line connecting both end points of $C$ and two tangent lines of $C$ at both end points of $C$. The intersection of $C$ and $L$ can be computed as follows.
if $(R(C) \cap R(L)=\varnothing)$ then $C \cap L=\varnothing$;
else if $(T(C) \cap L=\varnothing)$ then $C \cap L=\varnothing$;
else Let $p_{1}=\left(x_{1}, y_{1}\right)$ and $p_{2}=\left(x_{2}, y_{2}\right)$ be the starting and ending points of $L^{\prime}=T(C) \cap L$, then the intersect point(s) of $C$ and $L^{\prime}$ can be computed by the following Lemma;

Lemma 3.2.1: (I) If $C$ is a parametric curve segment given by $C(s)=(x(s) . y(s))$ with $a \leq s \leq b$, then $C$ intersects with $L^{\prime}$ at a point $p=C(s)=t \cdot p_{1}+(1-t) \cdot p_{2}$ if and only if $s$ and $t$ satisfy

$$
\left\{\begin{array}{l}
a \leq s \leq b, \text { and } 0 \leq t \leq 1  \tag{1}\\
x(s)=t \cdot x_{1}+(1-t) \cdot x_{2} \\
y(s)=t \cdot y_{1}+(I-t) \cdot y_{2}
\end{array}\right.
$$

(II) If $C$ is an implicit algebraic curve segment given by $f(x, y)=0$, then $C$ intersects with $L^{\prime}$ at a point $p=t \cdot p_{1}+(1-t) \cdot p_{2}$ if and only if $t$ satisfies

$$
\left\{\begin{array}{l}
p \in C \text { and } 0 \leq t \leq 1  \tag{1}\\
f\left(t \cdot x_{1}+(1-t) \cdot x_{2}, t \cdot y_{1}+(1-t) \cdot y_{2}\right)=0
\end{array}\right.
$$

Proof: Straightforward
Lemma 3.2.2: (I) For a parametric curve segment $C$, the curve-line segments intersection can be computed in $O\left(d^{3} \log d\right)$ time.
(II) For an implicit algebraic curve segment $C$, the curve-line segments intersection can be computed in $O\left(d^{3} \log d+T(d)\right)$ time, where $T(d)$ is the time required for a curve tracing along $C$.
Proof: (I) The elimination of $t$ can be done in $O$ (1) time resulting in a single polynomial of degree $d$ in a single variable $s$. This polynomial can be solved in $O\left(d^{3} \log d\right)$ time using root isolation, see Schwartz and Sharir (1983). There are at most $d$ solutions for $s$ with $a \leq s \leq b$ and the corresponding $t$ to each $s$ can be solved in $O$ (1) time.
(1I) When we expand the equation (2) in an increasing order of $t$, it gives a polynomial of degree $d$ in a single variable $t$. The expansion can be done in $O\left(d^{2}\right)$ time and the polynomial can be solved in $O\left(d^{3} \log d\right)$ time using root isolation. Finally, we need to trace along the curve segment $C$ to check whether these solutions are on the curve segment $C$ in $T(d)$ time.

## Containment in a Halfplane

The halfplane containment for points and line segments can be done in $O$ (1) time. Suppose $C$ is a convex monotone edges along which $x$ and $y$-coordinates are strictly increasing, $L$ is an infinite line with slope $m \geq 0$, and $H^{U L}(L)$ is the upper-left closed halfptane of the line $L$. These are the only types of curved edges and halfplanes considered in $\S 4$. Then, $C \subset H^{U L}(L) \Leftrightarrow p_{S}$ and $p_{E} \in H^{U L}(L)$, and $C \cap$ $L^{\prime} \neq \varnothing$, where $L^{\prime}=T(C) \cap L$; Hence, the time complexity of halfplane containment testing is the same as that of Line-Curve segments intersection.

## Common Supporting Line of a Curve Segment and a Point

Suppose $L$ is a common supporling line of a monotone curve segment $C$ and a point $q=(\alpha, \beta) \notin C$ such that $C \cup\{q\} \subset H^{V L}(L)$. Then the supporting point $p$ of $L$ at $C$ is given by the following Lemma.

Lemma 3.2.3: ( $\boldsymbol{( 1 )}$ If $C$ is given by a parametric curve $C(t)=(x(t)$. $y(t))$ with $a \leq t \leq b$, then $p=$ $(x(t), y(t))$ is given by

$$
\left\{\begin{array}{l}
a \leq t \leq b  \tag{1}\\
(x(t)-\alpha) \cdot y^{\prime}(t)-(y(t)-\beta) \cdot x^{\prime}(t)=0
\end{array}\right.
$$

(II) If $C$ is given by an implicit curve $f(x, y)=0$, then the point $p=(x, y)$ is given by

$$
\left\{\begin{array}{l}
f(x, y)=0 \text { and } p=(x, y) \in C  \tag{I}\\
(x-\alpha) \cdot f_{x}+(y-\beta) \cdot f_{y}=0
\end{array}\right.
$$

Proof : Straightforward.
Lemma 3.2.4: (I) For a parametric curve segment $C$, the common supporing line of $C$ and $q$ can be computed in $O\left(d^{3} \log d\right)$ time.
(II) For an implicit algebraic curve segment $C$, the common supporing line of $C$ and $q$ can be computed in $O\left(d^{6} \log d+T(d)\right)$ time, where $T(d)$ is the time required for a curve rracing.

Proof : Similar to Lemma 3.1.2.

## Common Supporting Line of Two Curve Segments

Suppose $L$ is a common supporting line of two disjoint monotone curve segments $C$ and $D$ such that $C \cup D \subset H^{U L}(L)$. Then the supporting points $p=(x, y)$ and $q=(\alpha, \beta)$ of $L$ at $C$ and $D$ respectively are given by the following Lemma.

Lemma 3.2.5: (I) If $C$ and $D$ are given by parametric curves $C(s)=(x(s), y(s))$ with $a \leq s \leq b$ and $D(t)=(\alpha(t), \beta(t))$ with $c \leq t \leq d$, then $p=(x(s), y(s))$ and $q=\langle\alpha(t), \beta(t))$ are given by

$$
\left\{\begin{array}{l}
a \leq s \leq b \text { and } c \leq t \leq d \\
(x(s)-\alpha(t)) \cdot \gamma^{\prime}(s)-(y(s)-\beta(t)) \cdot x^{\prime}(s)=0 \\
(x(s)-\alpha(t)) \cdot \beta^{\prime}(t)-(y(s)-\beta(t)) \cdot \alpha^{\prime}(t)=0
\end{array}\right.
$$

(II) If $C$ is given by a parametric curve $C(s)=(x(s), y(s))$ with $a \leq s \leq b$ and $D$ is given by an implicit curve $g(\alpha, \beta)=0$, then $p=(x(s), y(s))$ and $q=(\alpha, \beta)$ are given by

$$
\left\{\begin{array}{l}
a \leq s \leq b \\
g(\alpha, \beta)=0 \text { and } q=(\alpha, \beta) \in D \\
(x(s)-\alpha) \cdot y^{\prime}(s)-(y(s)-\beta) \cdot x^{\prime}(s)=0 \\
(x(s)-\alpha) \cdot g_{\alpha}+(y(s)-\beta) \cdot g_{\beta}=0
\end{array}\right.
$$

(III) If $C$ and $D$ are given by implicit curves $f(x, y)=0$ and $g(\alpha, \beta)=0$, then $p=(x, y)$ and $q=$ $(\alpha, \beta)$ are given by

$$
\left\{\begin{array}{l}
f(x, y)=0 \text { and } p=(x, y) \in C  \tag{1}\\
g(\alpha, \beta)=0 \text { and } q=(\alpha, \beta) \in D \\
(x-\alpha) \cdot f_{x}+(y-\beta) \cdot f,=0 \\
(x-\alpha) \cdot g_{\alpha}+(y-\beta) \cdot g_{\beta}=0
\end{array}\right.
$$

Proof: Straightforward
Lemma 32.6: (I) For parametric curve segments $C$ and $D$, the common supporting line of $C$ and $D$ can be computed in $O\left(d^{6} \log d\right)$ time.
(II) For a paramerric curve segment $C$ and an implicit algebraic curve segment $D$, the common supporing line of $C$ and $D$ can be computed in $O\left(d^{12} \log d+T(d)\right)$ time, where $T(d)$ is the time required for a curve tracing.
(III) For implicit algebraic curve segments $C$ and $D$, the common supporting line of $C$ and $D$ can be computed in $O\left(d^{24} \log d+T(d)\right)$ time, where $T(d)$ is the time required for curve tracings along $C$ and $D$.
Proof : Similar to Lemmas 3.1.2 and 3.2.4.

## 4. Convex Hull of Geometric Model

In this seclion we present an algorithm to compute the convex hull of planar curved objects bounded by $O(m)$ monotone curve segments which have been oblained in the preprocessing step from $O(n)$ algebraic curve segments of maximum degree $d$. In $\S 3$ each implicit (resp. parametric) algebraic curve segment of degree $d$ has been segmented into at most $O\left(d^{2}\right)$ (resp. $O(d)$ ) monotone curve segments by adding extra vertices into singular points, inflection points and extreme points. After this preprocessing step of monotone segmentation, the total number of boundary edges becomes $m$ which is $O\left(n \cdot d^{2}\right)$. The algorithm presented in this section nuns in $O(m)$ steps, where each step would take either (a) a constant
time if a simple coordinate comparison is enough to process an edge or (b) a polynomial time in the degree $d$ if a nontrivial operation on curve segments such as line-curve intersection or tangent line computation is required to process an edge. Detailed timing analysis will be given in §5. In the following we consider the construction of the Iower-right subpart of the convex hull boundary which lies between the bottom most vertex and the ightmost vertex of the original object. The entire convex hull is obtained by applying the same algorithm to the remaining three subparts. Since the minimum horizontal (resp. vertical) line segment containing all the bottommost (resp. rightnost) vertices is on the convex hull boundary, w.lo.g. we may assume there are unique botlommost and rightmost vertices. In the following, suppose $C_{1}, C_{2}, \ldots, C_{M}$ is a connected sequence of edges from the bottommost vertex $p_{0}$ to the rightmost vertex $p_{M}$, and each $C_{i}$ has $p_{i-1}$ and $p_{i}$ as its starting and ending vertices. For a point $p_{i}$ (resp. $p^{*}$ ) with subscript \# (resp. superseript \#) We denote the $x$ and $y$-coordinates of $p_{i}$ (resp. $p^{\prime \prime}$ ) by $x_{1}$ and $y_{f}$ (resp. $x^{\prime \prime}$ and $y^{\prime \prime}$ ). We also denote the line segment connecting two points $p$ and $q$ by $L(p, q)$ and the path from $p$ to $q$ along the boundary curve by $\gamma(p, q)$.

### 4.1. Sequences of Event Edge and Current Hull

We make a constructive definition of a sequence of event edges $\left\{C_{i}\right\}_{k=1}^{N}$ with $C_{i n}=C_{H}$ and a sequence of current hulls $\left\{\mathrm{CH}_{k}\right\}_{k=1}^{N}$. We show the following property of the $k$-th current hull $\mathrm{CH}_{k}$ :
(*) If $p \in \gamma_{0}\left(p_{0} p_{i_{1}}\right)$ is a point on the convex hull boundary, then $p \in C H_{k}$ and the front subarc of $C H_{k}$ between $p_{0}$ and $p$ is on the convex hull boundary.

This property (*) and the fact that $p_{M}$ is the end point of the $N$-th current hull $\mathrm{CH}_{N}$ imply that $\mathrm{CH}_{N}$ is the lower-right subpart of the convex hull boundary between two exrreme points $p_{0}$ and $p_{M}$.

## Definition of $\mathrm{C}_{i}$ and $\mathrm{CH}_{k}$

Let $i_{0}=0$ and $C H_{0}=\left\{p_{0}\right\}$. Assume that the index $i_{k}$ and the $k$-th current hull $C H_{k}(0 \leq k<N)$ have been defined. We define the $(k+1)$-th event edge $C_{i 60}$ and the $(k+1)$-th event component $E C_{k+1} \subset C_{i 4.1}$ in terms of $i_{k}$ and $\mathrm{CH}_{k}$ as follows, see Figmes 4.1.1-4.1.3.
(A) If $x_{i_{+1}} \leq x_{i_{i}}$ and the inner angle of $p_{i_{i}}<\pi$, then $i_{k+1}=\min \left\{j \mid j>i_{k}\right.$ and $\left.x_{j}>x_{k}\right\}$. Further, (a) $E C_{k+1}=C_{i, 1}$ if $y_{i_{+1,1}-1}<y_{i+1}$ and $C_{i, 1}$ is convex, and (b) $E C_{k+1}=p_{i_{4,1}}$ otherwise.
(B) If $x_{i_{4}}<x_{i_{2}+1}$ and $y_{i_{4}}<y_{i_{+1}}$, then $i_{k+1}=i_{k}+1$. Further, (a) $E C_{k+1}=C_{i_{2,1}}$ if $C_{i+1}$ is convex, and (b) $E C_{k+1}$ $=p_{i, 1}$ otherwise.
(C) Otherwise, let $y m i n_{j-1}\left(L\left(p^{\prime}, p^{\prime \prime}\right)\right)=\min \left\{y \in \mid p_{\mathrm{a}} \in \chi\left(p_{i_{i}}, p_{j-1}\right) \cap L\left(p^{\prime}, p^{\prime}\right)\right\}$ for $i_{k}<j-1$ (we define the lid $L\left(p^{\prime}, p^{\prime}\right)$ later). Further, let $\Omega_{k}=\{M\} \cup\left\{j \mid\right.$ (i) $i_{k}+1<j \leq M$, (ii) $y_{j-1}<y_{j}$, and (iii) either $C_{j}$ is totally ouside of any pocket of $\mathrm{CH}_{k}$ or $\left(C_{j}\right.$ is not totally inside of a pocket of $\mathrm{CH}_{t}$ and intersects with a lid $L\left(p^{\prime}, p^{\prime \prime}\right)$ at a point $p_{* *}$ with $\left.y_{* *}<\operatorname{limin}_{j-1}\left(L\left(p^{\prime}, p^{\prime \prime}\right)\right)\right)$, and Iet $j_{0}=\min$ $\Omega_{k}$. (a) If $x_{j,-1}<x_{j}$, then $i_{k+1}=j_{0}$ and ((a1) $E C_{k+1}=C_{i_{4,1}}$ if $C_{i_{k+1}}$ is convex, and (a2) $E C_{k+1}=$ $L$ ( $p_{i .1-1}, p_{i+1}$ ) otherwise). (b) Otherwise, $i_{k+1}=j_{0}-1$ and $E C_{k+1}=p_{i_{1,1}}$.
Next we define the ( $k+1$ )-th current hull $\mathrm{CH}_{t+1}$. It is easy to show there is a unique common supporting line $L$ of $C H_{k}$ and $E C_{k+1}$ at the points $p^{\prime}$ and $p^{\prime \prime}$ (with $x^{\prime}<x^{\prime \prime}$ and $y^{\prime}<y^{\prime \prime}$ ) respectively such that $C H_{k} \cup$ $E C_{k+1} \subset H^{U L}(L)$. If there is more than one choice of $p^{\prime}$ (resp. $p^{\prime \prime}$ ), we choose $p^{\prime}$ (resp. $p^{\prime \prime}$ ) so that the distance between $p^{\prime}$ and $p^{\prime \prime}$ to be minimal. Further, let $F R O N T_{-} C H_{k+1}$ denote the front subarc of $C H_{k}$ between the points $p_{0}$ and $p^{\prime}$, and $R E A R_{-} C H_{t+1}$ denote the rear subarc of $E C_{k+1}$ between the points $p^{\prime \prime}$ and $p_{i+1}$. The $(k+1)$-th current hull $C H_{k+1}$ is defined as the connected union $F R O N T_{-} C H_{k+1} \cup L\left(p^{\prime}, p^{\prime \prime}\right) \cup$ $R E A R_{1} \mathrm{CH}_{k+1}$, see Figure 4.1.4. $\mathrm{CH}_{k+1}$ is a convex arc along which both $x$ and $y$-coordinates are strictly
increasing. $L\left(p^{\prime}, p^{\prime \prime}\right)$ is called as the $l i d$ determined by $p^{\prime}$ and $p^{\prime \prime}$. Let $\bar{\gamma}$ be the closed path given as $\gamma\left(p^{\prime}, p^{\prime \prime}\right)$ followed by a path from $p^{\prime \prime}$ to $p^{\prime}$ along $L\left(p^{\prime}, p^{\prime \prime}\right)$. If $\bar{\gamma}$ has no self-intersection, the region bounded by $\bar{\gamma}$ is called as the pocket detemined by the lid $L\left(p^{\prime}, p^{\prime \prime}\right)$. Otherwise, $\chi\left(p^{\prime}, p^{\prime \prime}\right)$ has an even number of intersections with the lid $L\left(p^{\prime}, p^{\prime \prime}\right)$ counting intersections with multiplicities and $\bar{\gamma}$ divides the plane into finite number of connected regions. The union of all the regions which are to the right of $\bar{\gamma}$ is the pockes implied by $L$ ( $p^{\prime}, p^{\prime \prime}$ ), see Figure 4.1.5.

## Properties of $\mathrm{CH}_{t}$

The proof of property ( ${ }^{(*)}$ follows from the following Lemmas 4.1.1-4.1.2.
Lemma 4.1.1: If a point $p \in C_{i}\left(1 \leq i \leq i_{k}\right)$ is on the convex hull boundary, then $p \in C H_{1}$.
Proof: The interior of the path $\gamma\left(p_{i_{1}, p_{i .1}}\right)$, the arc $C_{i_{4 .+1}}-E C_{k+1}$, and $\left(C H_{k} \cup C_{i_{4.1}}\right)-C H_{k+1}$ are in the convex hull interior.

Lemma 4.1.2 : If a point $p \in \mathrm{CH}_{\boldsymbol{k}}$ is on the convex hull boundary, then the front subarc of $\mathrm{CH}_{\boldsymbol{k}}$ between $p_{0}$ and $p$ is entirely contained in the convex hull boundary.
Proof: The case $k=1$ is easy to show. By induction, we assume for $k(1 \leq k<N)$ and consider $k+1$. Suppose a point $p \in C H_{k+1}$ is on the convex hull boundary. (a) If $p \in F R O N T_{-} C H_{k+1} \subset C H_{k}$, then the statement follows by induction. (b) If $p \in L\left(p^{\prime}, p^{\prime \prime}\right)$, then $L\left(p^{\prime}, p^{\prime \prime}\right)$ is also on the convex hull boundary. Further, FRONT_ $_{-} \mathrm{H}_{k+1}$ is on the convex tull boundary by induction. (c) If $p \in$ REAR_CH ${ }_{t+1}$, then there is a supporting line $L_{p}$ at $p$. We prove the lid $L\left(p^{\prime}, p^{\prime}\right)$ is on the convex hull boumdary. Suppose there is a boundary point $q$ in the region $R_{1}$, see Figure 4.1.6. We may assume $q$ is extreme to the outward normal direction of the lid and thus on the convex hull boundary. (i) If $q \in C_{j}\left(1 \leq j \leq i_{k+1}\right)$, then Lemma 4.1.2 implies $q \in C H_{k+1}$. But, it's impossible since $C H_{k+1}$ is convex. (ii) Otherwise, there is a continuous path from $p_{i-1}$ ம $q$. This path should pass through either the region $R_{2}$ or $R_{3}$, but both are impossible. Hence, the lid $L\left(p^{\prime}, p^{\prime \prime}\right)$ is on the convex hull boundary, and by induction $F R O N T_{-} C H_{k+1}$ is also on the convex hull boundary. Similarly one can show that the subatc of $R E A R_{-} C H_{k+1}$ between $p$ " and $p$ is on the convex hull boundary.
Hence, each current hull $\mathrm{CH}_{\mathbf{L}}$ has the property (*). Since $p_{M}$ is the end point of both $C_{i}$ and $\mathrm{CH}_{N}$, Theorem 4.1.1 follows easily from Lemmas 4.1.1-4.1.2.

Theorem 4.1.1: $\mathrm{CH}_{N}$ is the lower-right part of the convex hull boundary between two extreme points $p_{0}$ and $p_{M}$.

### 4.2. Description of Algorithm

We describe an algorithm to compute the sequences of event edges $\left\{C_{i_{i}}\right\}_{k=1}^{N}$ and current hulls $\left\{\mathrm{CH}_{k}\right\}_{k=1}^{N}$ by using a single stack CH . CH contains segments of the $k$-th current hull $\mathrm{CH}_{k}$ which are subarcs of some convex edges, some linear edges and the lids of pockets. Adjacent elements on the stack share a common end point and the connected sequence of elements on the stack CH generates the current hull $\mathrm{CH}_{\mathrm{k}}$ (we call as the stack CH implies the current hull $\mathrm{CH}_{k}$ ).

## Computing Event Edges

We start with pushing a single point interval $\left[p_{0}, p_{0}\right]$ into an empty stack CH . The stack CH implies the current hull $\mathrm{CH}_{0}=\left\{p_{0}\right\}$. In general, suppose $i_{k}$ is detected and the stack $C H$ implies the $k$-th current hull $\mathrm{CH}_{k}(0 \leq k<N)$. To detect $i_{k+1}$ we call the procedure Detect_Event_Edge of Appendix I. Since the correctness of the cases (A) and (B) is obvious, we will consider the case (C) in the following.

An integer variable $j$ initialized to $i_{k}$ is used to detect $i_{k+1}$. The initial value of $j$ satisfies the following property.
(**) $C_{j}$ is not totally contained in an interior of any pocket of $\mathrm{CH}_{k}$, and TOP(CH) is not strictly below the horizontal line $y=y_{j}$.
Within the branch (C) there is a while-Ioop. Upon completion of each loop either $i_{k+1}$ has been detected or the loop-invariant (**) holds for the new $j$. We show this fact while describing the sub-branches (C1)(C3) in the following.

At the beginning of each Ioop, (**) holds and $j<\min \Omega_{k}$. After we increment $j$ by 1 , in (Cl) and (C2), $j=\min \Omega_{k}$ and $i_{k+1}$ and $E C$ are conrectly set to appropriate values. Further, in (C3), $j<\Omega_{k}$. To make the loop-invariant ( $* *$ ) hold we manipulate the stack $C H$. First of all, we check whether $p_{j}$ is an interior point of any pocket of $C H_{k}$. For this $j, p_{j}$ is an interior point of a pocket bounded by a lid $L\left(p^{\prime}, p^{\prime \prime}\right)$ if and only if $p_{j}$ is in the upper left open half plane of $L\left(p^{\prime}, p^{\prime \prime}\right)$ and $C_{j}$ intersects with $L\left(p^{\prime}, p^{\prime \prime}\right)$. Further, if $C_{j}$ intersects with $L\left(p^{\prime}, p^{\prime}\right)$, then $L\left(p^{\prime}, p^{\prime \prime}\right)$ is neither strictly above the horizontal line $y=y_{j-1}$ nor strictly below the line $y=y_{j}$, Since the current stack $C H$ contains all these elements, we need to examine only those elements not strictly below the line $y=y_{j}$ in a finite step. If the top stack element $\mathrm{TOP}(\mathrm{CH})$ lies strictly above the line $y=y_{j}$, it cannot be a lid bounding a pocket with $p_{j}$ in its interior. Since it is in the convex hull interior, we pop $\operatorname{TOP}(C H)$. We repeat this popping procedure until (a) an intersecting lid is found which bounds a pocket with $p_{j}$ in its interior, or (b) a non-intersecting element is found which is not strictly above $y=y_{j}$. In the case of (a), we have one right-to-left cut on the edge $C_{j}$. Right-to-left cut (resp. left-to-right cut) at a point $p$. is a transversal intersection of an edge $C$ with a lid at an interior point $p$. such that $C$ traverses from the right to the left (resp. from the left to the right) of the lid in the neighborhood of $p_{\text {. }}$. When the boundary curve transversally intersects at a vertex $p_{j}$, we consider the point $p_{j}$ as a point of $C_{j+1}$ and detemine the cut direction in a similar way. Whenever we meet a ransversally intersecting edge with a lid, we update the total number of right-to-left cuts and/or left-toright cuts. In Figure 4.1.7, a path $\gamma\left(p_{*}, p_{j}\right)$ is totally contained in a self-intersecting pocket and has its first interior intersection with a lid $L\left(p^{\prime}, p^{\prime \prime}\right)$ in a right-io-left direction. When $\gamma\left(p_{n}, p_{j}\right)$ comes out of a pocket through a point $p .6$, the total cuts in bolh directions are equal. Hence, we can delect the next edge not totally contained in a pocket by counting the cuts in both directions properly. To detect the next event edge satisfying the condition (C), we skip all the subsequent edges until an edge $C_{J}$, intersecting with $L\left(p^{\prime}, p^{\prime \prime}\right)$ at a point p.* such that the total number of right-w-left cuts and left-to-right cuts upto $p_{* *}$ are the same and $y_{0 .}<\operatorname{mmin}_{j-1}\left(L\left(p^{\prime}, p^{\prime \prime}\right)\right.$ ). (i) If $y_{j^{\prime}-1}<y_{j^{\prime},}$ then $j^{\prime}=\min \Omega_{k}$ and $i_{k+1}$ is set to $j^{\prime}$ correctly. (ii) Otherwise, the loop-invariant ( ${ }^{*} *$ ) holds after the assignment $j=j^{\prime}$. In (b), the loop-invariant ( $* *$ ) holds. Hence, we proved the following Theorem.

Theorem 4.2.1 : The algorithm Detect_Event_Edge detects the $(k+1)$-th event edge $C_{\text {Lut }}$.

## Computing Current Hulls

Now, we describe how to compute the ( $k+1$ )-th current hull $\mathrm{CH}_{k+1}$ from the $k$-th current hull $\mathrm{CH}_{\mathrm{k}}$ and the $(k+1)$-th event component $E C_{k+1}$ by using the stack $C H$. Since we are popping some stack elements so that $\operatorname{TOP}(C H)$ is neither strictly above nor strictly below the horizontal line $y=M N$, the stack CH may not $i m p l y$ the $k$-th current hull $C H_{k}$ when $E C_{k+1}$ is computed. However, the stack CH always contains all the elements necessary for the construction of the new slack $C H$ implying the ( $k+1$ )-th current hull $\mathrm{CH}_{k+1}$, i.e. the stack elements nol strictly above the horizontal line $y=M I N$. A detailed procedure to update the stack CH to a new stack CH implying $\mathrm{CH}_{k+1}$ is given as the procedure Update_Current_Hull in Appendix II, where SUPP1 ( $C, D$ ) (resp. SUPP2 $(C, D)$ ) rewins the supporting point $p^{\prime}$ at $C$ (resp. $p^{\prime \prime}$ at $D$ ) of the supporting line $L$ such that $C \cup D \subset H^{U L}(L)$.

In each loop we check whether $\operatorname{TOP}(\mathrm{CH})$ contains the common supporting point $p^{\prime}$ of $\mathrm{CH}_{k}$. We have ( $\alpha$ ) $p^{\prime}=p_{E}$ if and only if $E C \subset H^{U L}\left(L_{p_{A}}\right)$ and $E C$ is not strictly below the horizontal line $y=y_{E}$, ( $\beta$ ) $p^{\prime} \in \operatorname{TOP}(C H)$ if and only if $E C \subset H^{U L}\left(L_{p_{p}}\right)$, and $(\gamma) p^{\prime} \notin \operatorname{TOP}(C H)$ otherwise, where $p_{s}$ and $p_{E}$ are the starting and ending points of $\operatorname{TOP}(C H)$, and $L_{p}$, and $L_{p_{1}}$ are the cangent lines of $\operatorname{TOP}(C H)$ at $p_{S}$ and $p_{E}$ respectively. In the cases ( $\alpha$ ) and ( $\beta$ ), the loop terminates after setting $p^{\prime}$ and $p^{\prime \prime}$ appropriately. The correctness of the branches for ( $\alpha$ ) and ( $\beta$ ) is obvious. And, in ( $\gamma$ ), we pop the element TOP(CH) from the stack $C H$ and repeat the loop. Since $E C$ is in the upper half plane of the horizontal line $y=y_{0}$, the loop teminates in a finite step and the correctness of the algorithm follows by induction. Hence, we proved the following Theorem.

Theorem 4.2.2: The algorithm Update_Current_Hull computes the ( $k+1$ )-th current hull $\mathrm{CH}_{\mathbf{t}+1}$.

## Computing the Convex Hull

Using the above procedures to detect event edges and update current hulls we can design an algorithm to compute the lower-right subpart of the convex hull boundary between the bottommost vertex and the rightmost vertex as follows.

```
procedure Lower_Right_Convex_Hull;
begin
Let }CH=\varnothing\mathrm{ and }i=0\mathrm{ ;
Push [por, pol into CH;
while (i<N) do begin
    Detect_Event_Edge (CH,i,i,EC);
    Update_Current_Hull (CH,EC); end; (* while *)
end; (*Lower_Righf_Convex_Hull *)
```

The correctness of the procedures Detect_Event_Edge and Update_Current_Hull follows from Theorems 4.2.1-2. Since the above while-loop temninates at a finite step and $C_{M}$ is an event edge at some $N$-th step, the correctness of Lower_Right_Convex_Hull follows by induction and Theorem 4.1.1.

Theorem 4.2.3 : The algorithm Lower_Right_Convex_Hull computes the lower-right subpart of the convex hull boundary between the bonommost vertex and the rightmost vertex.

## 5. Algorithm Analysis

## Complexity of Event Edge Detection

We consider the time complexity required to manipulate the edge segments in the process of detecting next event edges. In the cases of (A) and (B), each edge requires $O(1)$ processing time since a simple coordinate comparison is enough to process an edge. But, in the case of (C), either finite number of simple coordinate comparisons or interseclions with a line segment are required to process an edge. The tolal numbers of coordinate comparisons and curve-line segments intersections are $O(m)$. Since many of curve-line segments intersection testings can be done in a finite number of simple operations using bounding triangle testings, etc., the actual number of curve-line segment intersections based on curve tracing, say $m_{1}$, would be much less than $m$ though the worst case complexity can be $O(m)$. Hence, the overall time complexity for event edge detections is $O\left(m+m_{1} \cdot d^{3} \operatorname{Iog} d\right)=O\left(m \cdot d^{3} \log d\right)=O\left(n \cdot d^{5} \log d\right)$. Even though we are also manipulating the stack CH while detecting next event edges, we will consider this cost in the following.

## Complexity of Current Hull Computation

We consider the time complexity required to manipulate the stack elements in the process of updating the current hulls. Each stack element is either (1) popped, (2) pushed, or (3) replaced by a subsegment of it. (1) The cost of popping a stack element can be charged to the stack element popped itself, and hence to the event edge which pushed this sack element. Since a stack element can be decided to be popped after an half-plane containment testing to the next event edge, each popping could be done within either (i) a constant time if finite simple operations are sufficient, or (ii) $O\left(d^{3} \cdot \log d+T(d)\right)$ time if a curve-line segment intersection is required, where $T(d)$ is the time required for curve tracing. (2) Each stack element first pushed is either a subsegment of an event edge or a lid common to this event edge. (3) Some stack elements need to be replaced to shorter subsegments. The replaced segment has a common lid with a new stack element which is a subsegment of the new event edge. We charge the cost for pushing and replacing to the new lid, and eventually to the new event edge. A lid is computed within either (iii) a constant time, (iv) $O\left(d^{6} \cdot \log d+T(d)\right)$ time if a tangent line computation from a point to a curve segment is required, or (v) $O\left(d^{24} \cdot \log d+T(d)\right)$ time if a common tangent line computation between two curve segments is required. Let $m_{2}$ be the number of event edges, and $m_{2,1}, m_{2,2}, m_{2,3}, m_{2,4}, m_{2,5}$ be the number of elements of type (i), (ii), (iii), (iv), (v). $m_{2,1}, m_{2,2}, m_{2,3}, m_{2,4}, m_{2,5}$ are $O\left(m_{2}\right)$, and $O\left(m_{2}\right)$ is $O(m)$. Hence, the total cost for manipulating stack elements takes $O\left(m_{21}+m_{2,3}+m_{2,2} \cdot\left(d^{3} \cdot \log d\right)+m_{24} \cdot\left(d^{3} \cdot \log d\right)+\right.$ $m_{25} \cdot\left(d^{6} \cdot \log d\right)=O\left(m_{2} \cdot\left(d^{6} \log d\right)\right)=O\left(m \cdot d^{6} \log d\right)=O\left(n \cdot d^{B} \log d\right) \quad$ (resp. $O\left(n \cdot\left(d^{26} \log d+d^{2} T(d)\right)\right)$ ) for object with all boundary curves as rational (resp. non-rational).

## 6. Conclusion

In this paper, we suggested an $O\left(n \cdot d^{\mathrm{B}} \log d\right)$ (resp. $O\left(n \cdot\left(d^{26} \log d+d^{2} T(d)\right)\right.$ ) algorithm to compute the convex hull of planar curved object bounded by $O(n)$ rational (resp. non-rational) algebraic curve segments. The true bound on $d$ for the latuer can be substantially reduced by use of the multivariant resultant, see Salmon (1885), Macaulay (1902), and Bajaj (1987). An accurate timing aralysis on computing the multivariate resultants is currenty underway. Though within the same asymptotic time complexity, this improves Schaffer and Van Wyk (1987) to the case of planar curved objects bounded by arbirrary algebraic curve segments. Main differences between this algorithm and Schaffer and Van Wyk (1987) are : (1) the boundary curves are segmented into monotone curve segments by adding inflection points and extreme points as vertices in a preprocessing step, (2) the original problem is divided into 4 subproblems instead of 2 subproblems, (3) the convex hull boundary is computed using a slack in a single pass instead of two pass, (4) it is a coordinated based algorithm instead of edge based algorithm, (5) this algorithm reduces the number of common tangent computation by detecting next event edges with a corect orientation.
