ACKNOWLEDGMENTS

The authors would like to express their thanks to Brad Smith and all of their colleagues on the Imaging Science Team for their help and interest in acquiring the data for this experiment and for their stimulating discussions during the mission planning phases and the exciting Jupiter encounters. We would like to thank Mary Brownell and Candice Hansen of JPL for preparing the picture-taking sequences for this experiment and Peter Kupferman, Larry Tietze, and Linda Morabido of JPL for star exposure data, star coordinates, and star plots. We are indebted to Leonard Dicken, Andrey Sergeevsky, and James Campbell of the Voyager Navigation Team for trajectory updates and to Frances Popescu of JPL for putting these data in machine-readable form for the Rand computer.

The maps used in the figures were prepared by the USGS, Flagstaff, under the direction of Raymond M. Batson. Patricia M. Bridges (Io and Callisto) and Jay L. Inge (Europa and Ganymede) made the surface interpretations and beautiful airbrush renditions.

James A. Roth, Thomas A. Hauge, and David Douglass of Rand were responsible for the selection, identification, and measurements of the control points on the individual pictures. We are appreciative of their dedication and care in carrying out this important part of the work.

This task was carried out at Rand under JPL Contract No. 953613 and NASA Contract No. NASW-3210.

PRECEDING PAGE BLANK NOT FILMED

## I. INTRODUCTION

One product of the current exploration of the solar system is the publication of maps of those bodies with solid surfaces. These maps show the relative positions of topographic features, one-to-another, and are used as bases for correlating a variety of measurements and pictorial data and for regional geologic mapping. In order to produce a map of a planetary surface, it is necessary to first establish a coordinate system for the body and then to determine the latitudes and longitudes of topographic features in this coordinate system. It is the purpose of this paper to define the coordinate systems of each of the Galilean satellites and to present coordinates of features seen in the Voyager pictures of these satellites. The two Voyager encounters with Jupiter are described in Smith et al. (1979a,b). A preliminary report on the progress of the control nets of the Galilean satellites was published by Davies et al. (1979).

The method for computing the control net of these satellites is essentially the same as that used at Mars (Davies, 1972; Davies and Arthur, 1973) and at Mercury (Davies and Batson, 1975) and will not be reviewed here.

Each spacecraft carried two cameras, one with a wide-angle lens and one with a narrow-angle lens. They can be shuttered independently or simultaneously. Pictures were taken of the Pleiades and other star clusters for calibration--using the known coordinates of the stars seen in the pictures, the camera orientation matrices,  $C$ , can be determined as well as the focal distances of the camera lenses. The focal distances of the Voyager 1 cameras are 200.293 mm and 1500.19 mm, and those of the Voyager 2 cameras are 200.770 mm and 1503.49 mm (Davies et al., 1979). The matrix relating the orientation of the wide-angle camera to that of the narrow-angle camera can be computed from frames taken simultaneously by each camera. This matrix,  $C_{NA WA}^{-1}$ , is given in Table 1 (Davies et al., 1979).

## II. THE SATELLITE COORDINATE SYSTEMS

The International Astronomical Union has defined coordinate systems for many of the planets and satellites of the solar system (*IAU Transactions*, 1979). The coordinate systems of synchronous satellites, like the Galilean satellites, are based on a resolution adopted in 1973 (*IAU Transactions*, 1974). These IAU-recommended coordinates were the starting point for the Voyager coordinate systems of the satellites.

The *IAU Transactions*, 1979, contain expressions for the direction of the north poles and the position of the prime meridians of the four satellites. These expressions are given in standard Earth equatorial coordinates of 1950.0 and, except for the rotation term in the positions of the prime meridians, vary slowly with time. Because the two Voyager spacecraft encounters with Jupiter were separated by only four months, the directions of the north poles were computed at a single time and assumed constant for both encounters (Davies et al., 1979). The angle  $W$  is measured along the satellite's equator in an easterly direction with respect to the satellite's north pole from the ascending node of the satellite's equator on the standard Earth equator (1950.0) to the point where the prime meridian crosses the satellite's equator. This led to the following values:

Io	$\alpha_0 = 268^{\circ}01$ $\delta_0 = 64^{\circ}54$ $W = 262^{\circ}7 + 203^{\circ}4889538d$
Europa	$\alpha_0 = 269^{\circ}07$ $\delta_0 = 64^{\circ}34$ $W = 156^{\circ}9 + 101^{\circ}3747235d$
Ganymede	$\alpha_0 = 268^{\circ}45$ $\delta_0 = 64^{\circ}62$ $W = 195^{\circ}8 + 50^{\circ}3176081d$
Callisto	$\alpha_0 = 268^{\circ}25$ $\delta_0 = 64^{\circ}62$ $W = 158^{\circ}0 + 21^{\circ}5710715d$

where  $d = \text{JED}-2433282.5$ .

A point, P, on the surface of a satellite has cartographic coordinates latitude  $\phi$ , west longitude  $\lambda$ , and radius R, and rectangular coordinates X, Y, Z, where  $X = R \cos \phi \cos (360^\circ - \lambda)$ ,  $Y = R \cos \phi \sin (360^\circ - \lambda)$ , and  $Z = R \sin \phi$ . Because the X, Y, Z coordinate system is right-handed,  $360^\circ - \lambda$  is used in the expressions for X and Y. The Z axis is the axis of rotation of the satellite with north positive. The X axis lies in the plane of the equator, positive in the direction of  $0^\circ$  longitude. The Y axis lies in the plane of the equator, positive in the direction of  $270^\circ$  west longitude. The standard equatorial coordinates of 1950.0 of the point  $P_x, P_y, P_z$  can be expressed as

$$\begin{bmatrix} P_x \\ P_y \\ P_z \end{bmatrix} = MV \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}$$

where

$$M = \begin{bmatrix} \cos(\alpha_0 + 90^\circ) & -\sin(\alpha_0 + 90^\circ) \cos(90^\circ - \delta_0) & \sin(\alpha_0 + 90^\circ) \sin(90^\circ - \delta_0) \\ \sin(\alpha_0 + 90^\circ) & \cos(\alpha_0 + 90^\circ) \cos(90^\circ - \delta_0) & \cos(\alpha_0 + 90^\circ) \sin(90^\circ - \delta_0) \\ 0 & \sin(90^\circ - \delta_0) & \cos(90^\circ - \delta_0) \end{bmatrix}$$

and

$$V = \begin{bmatrix} \cos W & -\sin W & 0 \\ \sin W & \cos W & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

If a picture containing P is taken by the spacecraft at  $S_x, S_y, S_z$ , the coordinates  $X_c, Y_c$  of P on the picture are given by

$$X_c = \frac{\xi}{\zeta} f, \quad Y_c = \frac{\eta}{\zeta} f,$$

where

$$\begin{bmatrix} \xi \\ \eta \\ \zeta \end{bmatrix} = C \begin{bmatrix} P_x \\ P_y \\ P_z \end{bmatrix} - C \begin{bmatrix} S_x \\ S_y \\ S_z \end{bmatrix},$$

and  $f$  is the calibrated principal distance (focal length) and  $C$  is the transformation matrix from standard coordinates of 1950.0 into the camera coordinate system.  $X_c, Y_c, f$  are expressed in millimeters and  $R, P_x, P_y, P_z, S_x, S_y, S_z$  are in kilometers.

Coordinates of the point  $P$  are measured on the picture by counting pixels (picture elements) and then removing the vidicon distortions and scaling the pixel coordinates to millimeter coordinates  $X_o, Y_o$  at the faceplate of the vidicon. The reseau is used in this transformation. The pixel measurements on the pictures are estimated to the one-tenth pixel and in general are repeatable to a few tenths of a pixel.

Standard photogrammetric methods are used to solve for the unknowns (see, for example, Davies and Arthur, 1973). Approximate values of all parameters are required to initiate the analytical triangulation. The triangulation is a problem in least squares designed to minimize the sum of the squares of the residuals, i.e.,  $(X_o - X_c), (Y_o - Y_c)$ . Observation equations are expressed in terms of those parameters whose values are permitted to vary; the normal equations are formed and solved to give improved values to the desired parameters. In practice, the spacecraft positions  $S_x, S_y, S_z$  are never permitted to vary, and the angles of the  $C$  matrix are usually variable, as are the latitude  $\phi$  and longitude  $\lambda$  of the control points. The radius at the control points can be fixed, a single mean radius determined for all points, or the radius at each point determined independently.

The control nets of the satellites are computed by means of single-block analytical triangulations. The normal equations are solved by the conjugate gradient iterative method, which is convenient and converges rapidly as the initial estimates of the parameters

are very good. A summary of the control net computations is given in Table 2.

Table 2  
SUMMARY OF CONTROL NET COMPUTATIONS OF THE GALILEAN SATELLITES

Parameter	Io	Europa	Ganymede	Callisto
Points	355	106	865	375
Pictures	210	103	137	161
Observation equations	6230	2086	6392	4358
Normal equations	1340	521	2141	1233
Overdetermination factors	4.65	4.00	2.99	3.53
Standard error of measurement, mm	0.02148	0.01497	0.03769	0.02197
Mean radius, km	1816 <sub>+5</sub>	1569 <sub>+10</sub>	2631 <sub>+10</sub>	2400 <sub>+10</sub>

The spacecraft trajectories used in the analytical triangulations result from a study by the JPL Voyager Orbit Determination Group, headed by James K. Campbell. This study used pictures taken and reduced by the Optical Navigation Group to update simultaneously the two Voyager trajectories and the ephemerides of the four Galilean satellites. The spacecraft positions relative to the centers of mass of the satellites ( $S_x$ ,  $S_y$ ,  $S_z$ ) are required for the analytical triangulations.

During the picture-taking sequences it was possible occasionally to take simultaneous pictures with the wide-angle and narrow-angle cameras in which two satellites were in the wide-angle frame and one of them with useful surface detail was in the narrow-angle frame. Knowing the locations of the satellites, the wide-angle camera orientation matrix  $C_{WA}$  could be determined, and since the matrix  $C_{NA}C_{WA}^{-1}$  was known from the star calibrations, the narrow-angle camera orientation matrix could be calculated:  $C_{NA} = C_{NA}C_{WA}^{-1}C_{WA}$ . Thus, in the control net computations, the camera orientation matrices of a few frames are constrained by weights. Those frames with C matrices computed from simultaneous exposures are given in Table 3.

Table 3

NARROW-ANGLE FRAMES WITH ORIENTATION MATRICES  
CONSTRAINED BY SIMULTANEOUSLY EXPOSED WIDE-ANGLE FRAMES

	16323.08	1423J1-003	91.1

Peale (1977) proved that, within a few degrees, the rotation axes of the Galilean satellites are normal to their orbital planes at all times. With this information, the directions of the north poles of the Galilean satellites were derived by Lieske (1979) and adopted by the IAU (*Transactions*, 1979). Using control net data, analytical triangulations were carried out in which the direction of the spin axis was treated as an unknown. The results of these computations, given in Table 4, confirm Peale's analysis and suggest that these results do not offer improvements over the IAU recommendations.

Preliminary attempts have been made to solve for  $a$ ,  $b$ , and  $c$ , the principal radii of the triaxial ellipsoid which describes Io's surface. If the satellite were homogeneous and in hydrostatic equilibrium, then  $a - c = 15.6$  km and  $b - c = 3.9$  km (Dermott, 1979). Early results indicate that Io is not in hydrostatic equilibrium. Computations using

Table 4

THE DIRECTIONS OF THE NORTH POLES OF THE GALILEAN SATELLITES  
AS MEASURED BY CONTROL NET COMPUTATIONS

Satellite	IAU North Pole Direction		Measured North Pole Direction with Estimated Error	
	$\alpha_0$	$\delta_0$	$\alpha_0$	$\delta_0$
Io	268°01	64°54	267°91 $\pm$ 0°01	64°56 $\pm$ 0°01
Europa	269°07	64°34	268°91 $\pm$ 0°26	64°27 $\pm$ 0°06
Ganymede	268°45	64°62	268°56 $\pm$ 0°32	64°64 $\pm$ 0°07
Callisto	268°25	64°62	268°10 $\pm$ 0°21	64°38 $\pm$ 0°09

5368 measurements of 319 points on 193 pictures indicate that  $a - c$  is less than 4 km and  $b$  is approximately equal to  $c$ . The errors associated with the solutions for  $a - c$  and  $b - c$  are rather large, perhaps 5 km, so there is still considerable uncertainty in the results. If, however, these measurements should be accurate, they will have important implications regarding the evolution, internal composition, and physical state of Io. In the future, with additional work, it should be possible to improve these measurements and lower the corresponding errors.

The system of longitudes on Mars (Davies and Arthur, 1973) and Mercury (Davies and Batson, 1975) has been defined by surface features. The intent is to do the same for the Galilean satellites. However, at Io it is not obvious how to select a small, *permanent* feature which can be identified on future missions because of the high rate of resurfacing due to volcanism (Johnson et al., 1979; Morrison et al., 1979). For this reason, no change is suggested for the definition of longitudes on Io from that of the IAU (*Transactions*, 1979). Small craters, as yet unnamed, near the equators have been selected to define the longitude systems on Europa, Ganymede, and Callisto.

On Europa, point 52 defines 182° longitude

On Ganymede, point 1000 defines 134° longitude

On Callisto, point 400 defines 326° longitude

These longitudes differ from the IAU longitudes by less than 0°5, according to the current control net computations. The points can be seen on Figs. 1 to 3.

The Voyager coordinate system now in use for the Galilean satellites has the following values for the direction of the spin axis and prime meridian in standard Earth equator (1950.0) coordinates:

Io	$\alpha_0 = 268^{\circ}01$ $\delta_0 = 64^{\circ}54$ $W = 262^{\circ}7 + 203^{\circ}4889538d$
Europa	$\alpha_0 = 269^{\circ}07$ $\delta_0 = 64^{\circ}34$ $W = 157^{\circ}2657 + 101^{\circ}3747235d$
Ganymede	$\alpha_0 = 268^{\circ}45$ $\delta_0 = 64^{\circ}62$ $W = 195^{\circ}8153 + 50^{\circ}3176081d$
Callisto	$\alpha_0 = 268^{\circ}25$ $\delta_0 = 64^{\circ}62$ $W = 157^{\circ}9895 + 21^{\circ}5710715d$

where  $d = \text{JED} - 2433282.5$ .

III. COORDINATES OF THE CONTROL POINTS

The control points are selected and identified on individual frames and their position measured by counting pixels on the pictures. These measurements are corrected for geometric distortions using the reseau and scaled to millimeter coordinates in the camera focal plane. They may then be incorporated into the analytical triangulation.

Control points that are easily seen are identified on U.S. Geological Survey 1:25,000,000 scale maps of the satellites, as shown in Figs. 4 through 7. Most of the points are too small to be seen on these maps, and there are too many to identify here. A few of the points correspond to features that have been given names by the IAU Working Group on Solar System Nomenclature (*Transactions*, 1979). To aid in their identification, they have been listed in Tables 5 through 8. The coordinates of the control points are given in Tables 9 through 12.
