Abstract

Background: Although radical surgery remains the cornerstone of cure in resectable gastric cancer, survival remains poor. Current evidence-based (neo)adjuvant strategies have shown to improve outcome, including perioperative chemotherapy, postoperative chemoradiotherapy and postoperative chemotherapy. However, these regimens suffer from poor patient compliance, particularly in the postoperative phase of treatment. The CRITICS-II trial aims to optimize preoperative treatment by comparing three treatment regimens: (1) chemotherapy, (2) chemotherapy followed by chemoradiotherapy and (3) chemoradiotherapy.

Methods: In this multicentre phase II non-comparative study, patients with clinical stage IB-IIIC (TNM 8th edition) resectable gastric adenocarcinoma are randomised between: (1) 4 cycles of docetaxel+oxaliplatin+capecitabine (DOC), (2) 2 cycles of DOC followed by chemoradiotherapy (45Gy in combination with weekly paclitaxel and carboplatin) or (3) chemoradiotherapy. Primary endpoint is event-free survival, 1 year after randomisation (events are local and/or regional recurrence or progression, distant recurrence, or death from any cause). Secondary endpoints include: toxicity, surgical outcomes, percentage radical (R0) resections, pathological tumour response, disease recurrence, overall survival, and health related quality of life. Exploratory endpoints include translational studies on predictive and prognostic biomarkers.

Discussion: The aim of this study is to select the most promising among three preoperative treatment arms in patients with resectable gastric adenocarcinoma. This treatment regimen will subsequently be compared with the standard therapy in a phase III trial.

Trial registration: [clinicaltrials.gov NCT02931890](https://clinicaltrials.gov/NCT02931890); registered 13 October 2016. Date of first enrolment: 21 December 2017.

Keywords: Gastric cancer, Resectable, Preoperative treatment, Chemotherapy, Chemoradiotherapy, Surgery

Background

Gastric cancer is the fifth most common malignancy worldwide [1]. In Western countries, gastric cancer patients often present with advanced disease. The 5-year survival rate after surgery alone in resectable gastric cancer is 20–35% [2, 3]. To improve these poor outcomes, different strategies have been evaluated.

Based on the Dutch D1D2 trial, D2 lymphadenectomy with removal of at least 15 lymph nodes is the current recommended surgical approach in patients with potentially curable gastric cancer [4].

In addition to a more extended resection, several (neo-)adjuvant treatments have been evaluated in phase II and III trials. An overview of all published and ongoing randomised (neo-)adjuvant clinical trials in resectable gastric and/or gastro-oesophageal junction (GOJ) cancer published since 1990 is provided in Table 1.

In the SWOG/Intergroup trial, 556 patients with resectable gastric or GOJ cancer were randomised between surgery alone versus surgery plus postoperative chemoradiotherapy (CRT) (45 Gy plus 5-fluorouracil (5-FU) and leucovorin). The CRT arm showed significantly improved overall survival (OS) [5]. The three-year OS rates were 41% in the surgery alone group compared to 50% in the CRT group [5]. An updated analysis showed persistent benefit from adjuvant CRT [6].

In 2005, the final results of the MAGIC trial were presented. In this trial, 503 patients with resectable adenocarcinoma of the stomach, GOJ or lower oesophagus were randomised to either perioperative chemotherapy (CT) or surgery alone. Chemotherapy consisted of 3 preoperative and 3 postoperative cycles of epirubicin, cisplatin and 5-FU (ECF). This perioperative regimen of ECF significantly decreased tumour size and induced downstaging. The five-year OS improved significantly from 23% in the surgery alone group to 36% in the perioperative CT group [7].

Many studies have investigated the effect of postoperative CT on survival rates. A meta-analysis from the GASTRIC Group, published in 2010, revealed a significant survival benefit favouring postoperative fluorouracil regimens with a hazard ratio of 0.82 (95% confidence interval (95%CI) 0.76–0.90; $p < 0.001$). The five-year OS increased from 49.6 to 55.3% with postoperative CT. It should be noted that a substantial number of the 17 included studies were carried out

in Asia, where patient populations, tumour characteristics and surgical procedures are different compared to the Western world [8].

Current European guidelines include multiple (neo-)adjuvant treatments for patients with resectable gastric cancer [9]. The CRITICS-study was designed to compare OS between patients treated with preoperative CT followed by surgery and postoperative CT versus postoperative CRT [10]. Postoperative CRT did not improve OS as compared to postoperative CT after adequate preoperative CT and surgery [11]. Hence, multiple treatment options remain currently available for patients with locally advanced, resectable gastric cancer. Which patients benefit from which (neo)adjuvant strategy should be addressed in future clinical trials.

There are several important issues that should be addressed in such future studies; which form the rationale behind the CRITICS-II trial. First of all, in most (neo)adjuvant studies patient compliance is low, especially in the postoperative phase (Table 2): 40–60% of patients are not able to complete treatment, mostly due to toxicity, disease progression or patient refusal. Second, there is need for more effective (neo-) adjuvant treatment with equal/less toxicity compared to the widely used epirubicin containing CT. Replacing epirubicin by docetaxel seems to be more effective [12–14], and is considered safe and tolerable [15]. Third, preoperative treatment increases the likelihood of tumour downsizing/downstaging and to achieve surgical radical (R0) resection, as shown in the MAGIC and the CROSS trials [7, 16]. An overview article reported 70–100% radical (R0) resections and a pathological Complete Response (pCR) of 7–29% in patients with resectable gastric cancer, preoperatively treated with CRT [17].

Finally, preoperative (C)RT allows a more accurate definition of the radiation target volume and margins compared to postoperative (C)RT, which may potentially limit toxicity. For oesophageal cancer, preoperative CRT showed improved survival with acceptable toxicity rates and > 90% patients being able to complete the entire treatment [16].

Based on these considerations, the aim of the current study is to optimise preoperative treatment by comparing three neo-adjuvant treatment modalities: (1) CT, (2) CT plus CRT, and (3) CRT.

Methods

Study design and objectives

The CRITICS-II study is a multicentre, non-comparative randomised phase II trial. The study is currently recruiting in several centres in The Netherlands. Randomisation is computer generated and will be performed and registered by the data managers. Stratification factors include Lauren classification (intestinal, diffuse, unclassifiable) and centre. The primary objective is to assess 1 year event-free survival in patients treated with preoperative CT, preoperative CT followed by CRT, or preoperative CRT (Fig. 1).

Event-free survival (EFS) is defined as interval between randomisation and local and/or regional recurrence or progression, distant recurrence or death from any cause.

Secondary endpoints are: toxicity, percentage radical (R0) resections, pathological tumour response, disease recurrence, overall survival and health related quality of life (HRQOL). Exploratory endpoints include translational studies into the relationship between classical

histological and clinical parameters, the identification of new biomarkers that predict clinical outcome and response, genomic changes in circulating tumour-derived DNA for diagnosis of different molecular subtypes of gastric cancer, and as biomarkers for response to treatment.

Patient selection and preoperative staging

Patients will be informed and treated by their treating physician. Patients with histologically proven, stage IB-IIIC (TNM 8th edition), resectable gastric adenocarcinoma are eligible for this study. Patients with tumours at the gastro-oesophageal junction (GOJ) may be included, but the tumour bulk has to be in the stomach. Patients should be ≥18 years old and should have WHO performance status < 2. Patients must have adequate haematological, renal and liver function. A staging laparoscopy is mandatory for all patients. At staging laparoscopy, biopsies from suspicious peritoneal lesions and/or free peritoneal fluid if any, should be pathologically proven tumour negative. Patients should have caloric intake ≥1500 kcal/day, verified by a dietician before registration. If caloric intake is < 1500 kcal/day or if bodyweight has decreased > 10% over the last 6 months or > 5% over the last month, dietary intervention such as oral nutritional support or via an enteral feeding tube is mandatory.

Exclusion criteria include: T1 N0 disease (assessed by endoscopic ultrasound), distant metastasis, inoperable/irresectable patients, previous malignancy, solitary functioning kidney within the potential radiation field and gastro-oesophageal stent within the radiation field. Required baseline investigations prior to randomisation consist of blood tests, dietician visit, oesophagoduodenoscopy with representative tumour biopsy samples, computed tomography of the chest and abdomen, staging laparoscopy, renography if there are signs on computed tomography abdomen and/or biochemically signs of impaired renal function. Endoscopic ultrasound (for >T1 N0 disease) and performing a FDG-PET/ computed tomography scan are optional per centre.

Fig. 1 Randomisation scheme CRITICS-II trial

Treatment arms

All treatment arms will start within 15 working days after randomisation. Patients in arm 1 receive four cycles of docetaxel+oxaliplatin+capecitabine (DOC) at a three-weekly interval preoperatively. Patients in arm 2 receive two cycles of DOC at a three-weekly interval, followed by CRT (weekly paclitaxel and carboplatin concurrent with radiotherapy). Chemoradiotherapy starts 3 weeks after start of the second DOC cycle. Patients in arm 3 receive CRT. Prior to surgery, a computed tomography will be performed to exclude progressive disease.

Patients can withdraw their informed consent at any time for any reason if they wish so without any consequences. The investigator can decide to withdraw a patient from the study for urgent medical reasons.

Preoperative study treatment: Chemotherapy

Chemotherapeutic treatment consists of docetaxel 50 mg/m² on day 1, followed by oxaliplatin 100 mg/m² on day one, followed by capecitabine 850 mg/m² b.i.d. orally on days 1–14. All drugs are administered in a cycle of 21 days. For capecitabine, drug tablet return and a diary are provided. Dose could be discontinued/reduced in case of severe toxicities.

Preoperative study treatment: Chemoradiotherapy

Radiotherapy consists of 45 Gy in 25 fractions of 1.8 Gy, 5 fractions per week for 5 weeks using image guided intensity modulated radiotherapy/volumic arc therapy (IMRT/VMAT) techniques. The *Clinical Target Volume* (CTV) has to be delineated on CT-images based on all available diagnostic information and should include the tumour, stomach and first draining lymph node stations. For quality assurance, a treatment delineation atlas is available and planning audits are performed. All delineations will be centrally reviewed and if necessary corrected before start of treatment.

Concurrent with radiotherapy, weekly CT is administered. Paclitaxel at a dose of 50 mg/m² and carboplatin Area Under the Curve (AUC) = 2 are given by intravenous infusion on days 1, 8, 15, 22 and 29. Radiotherapy starts at the first day of the first cycle of CT. Radiotherapy and/or chemotherapy dose could be discontinued/reduced in case of severe toxicities.

Surgery

Surgery is planned 3–4 weeks after preoperative treatment in arm 1 and 6–8 weeks after preoperative treatment in arms 2 and 3. The standard surgical procedure is a (sub)-total gastrectomy with a D2 lymph node dissection. A minimum of 15 lymph nodes should be removed. Lymph nodes will be submitted in separate pots, or alternatively, will be clearly marked at the resection specimen. Surgical technique is either open or laparoscopic.

Pathology

The pathology report includes at least the following items: tumour type, localisation, size of tumour, surgical margins, response to neo-adjuvant therapy in the primary tumour and the lymph nodes (by nodal station), presence of lymphatic invasion, presence of venous invasion, surgical stage, number of (positive) lymph nodes.

All tumours are classified using the Lauren classification (intestinal, diffuse and unclassifiable). For staging, the TNM 8th edition is used. Biopsies, photographs, resection specimen and when performed fresh frozen specimen will be sent for central pathological review. Pathological response according to the Becker scoring system [18] and the Mandard scoring system [19] will be investigated in central pathological review.

Quality of life

Health related quality of life will be carried out in cooperation with the Prospective Observational Cohort study of Oesophagogastric cancer Patients (POCOP), which is a prospective nationwide study to investigate HRQL in oesophagogastric cancer of all stages [20]. Health related quality of life will be assessed at baseline (before start preoperative treatment), pre-surgery and from surgery every 3 months in the first year, every 6 months in the second year and yearly thereafter until 5 years.

Translational research: Circulating tumour DNA (ctDNA)

Patients can optionally participate in this part of the protocol. All patients participating in this part of the protocol need to have signed informed consent specifically for this optional side study of the trial. Blood will be collected at baseline before start of any of the preoperative treatment modalities, after every preoperative treatment modality, after surgery and at every follow-up visit until 5 years after surgery or until recurrence. Material processing and storage will be done centrally at the VU University Medical Center.

Toxicity and (serious) adverse events

Toxicity during this trial is scored using the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0. Serious adverse events are defined according to the rules of good clinical practice and must be reported within one working day and are reported once yearly in the annual safety report. The Clavien-Dindo grading system is used for the classification of surgical complications [21].

Follow-up

After treatment, patients are followed by all treating medical specialists. The follow-up moments in the first year are, counted from surgery, at 1, 3, 6 and 12 months. From the second year, follow-up will occur every 6 months until

5 years after surgery. To enable evaluation of the primary endpoint, one-year EFS, CT chest and abdomen will be performed 1 year after randomisation.

Protocol amendments

Future protocol modifications will be submitted as amendment at the central medical ethics committee. After obtaining approval, this will be communicated to the participating sites by the study coordinator or project manager.

Data management and responsibilities

The central data management, data processing and statistical analysis of this study are performed at the Biometric Department of the sponsor. The study coordinators are responsible, in cooperation with the Data Centre, for writing the protocol, reviewing all case report forms, reporting and correctness of SAE. They are also responsible for answering clinical questions, treatment and evaluation of the patients and for publishing study results. Authors on the key-publication includes at least the protocol writing committee and additional a maximum of three authors per centre. The key-publication will be submitted to a major, peer-reviewed journal. Data is entered by data managers into a coded electronic case-report form. The study will be considered as a medium risk according Dutch Federation of University Medical Centres guidelines. Site monitoring will be performed by an independent Clinical Research Monitor or the person to whom the monitoring tasks have been delegated. The monitor will judge: compliance with the protocol, all applicable regulatory requirements, informed consent, source data verification, investigator study file, SAE/Serious Unexpected Serious Adverse Reactions. If necessary, active feedback will be provided to the participating sites. The study will be monitored and an auditing trail will not be performed routinely. The study coordinators will have access to the final dataset. Queries will be sent in case of missing data.

Statistics

The primary endpoint of this trial is EFS at 1 year. Statistical analysis will be performed on basis of intention to treat analysis. For each treatment arm, a 1-year EFS of 60% is considered insufficient and a 1-year EFS of 75% is active enough to further explore in a phase III study, taking other endpoints in consideration. The 1-year EFS of 60% is based on results of the MAGIC [22] and the CRITICS trial [11]. The design calculations assume Weibull distributions (shape = 1), which is equivalent to an exponential distribution. Scale parameters were chosen such that 1 year EFS would be 60% and 75% respectively. The type I (α) error is fixed at 10% (one-sided) and power is set at 90%. The R package OptInterim minimising the expected sample size was used for calculating the sample size for each stage as

well as the time of interim and final analyses. We used exact binomial correction adjusting all sample size and analysis times.

The trial is designed as a two-stage trial with one interim analysis at which futile arms are discontinued. Because the primary endpoint is evaluated at 1 year, the commonly used Simon's two stage design would imply up to 1 year in which the trial would be put on hold. To improve the efficiency, we will use the two stage design for survival endpoints as proposed by Case and Morgan [23].

The expected accrual is 30 patients per arm per year. After accruing 42 patients in each arm, the interim analysis will be performed. Futile arms will be discontinued and the remaining arms will accrue 27 more patients each (to a total of 69 patients in each arm). Final analysis will be performed 1 year after accrual of last patient. In both stages the null hypothesis will be evaluated using Lin's statistics [24]. If in the final analysis more than one arm will reject the null hypothesis, the decision about which arm should continue to the phase III trial will be made based on the Kaplan Meier point estimates of the 1-year EFS in combination with other factors such as toxicity, cost, convenience and quality of life.

Discussion

Here we describe the study protocol of the CRITICS-II trial, a clinical phase II study aimed at identifying a new and optimal preoperative treatment in patients with resectable gastric cancer by comparing three preoperative treatment arms. Several considerations have led to the design of this trial. First, patients' compliance, especially in the post-operative phase of the treatment, is low (Table 2). Second, there is need for a more effective (neo)adjuvant treatment [12–14], that is why we incorporated a docetaxel containing CT regimen in this trial. Third, preoperative treatment increases the likelihood of tumour downsizing/downstaging and to achieve tumour free resection margins [7, 16]. The last consideration is that preoperative (chemo)radiotherapy allows a more accurate definition of the radiation target volume and margins, which may potentially limit toxicity in patients receiving preoperative CRT.

Epirubicin containing CT regimens (epirubicin+cisplatin/oxaliplatin+capecitabine; ECX/EOX) are widely used in the preoperative setting, as recommended by European guidelines [9]. The choice to incorporate DOC as CT regimen was based on several studies.

Naj Mohammad et al. investigated efficacy and safety of triplet versus doublet CT in locally advanced or metastatic oesophagogastric carcinoma. When subgroups were examined, especially triplet CT with taxane, cisplatin and fluoropyrimidine revealed significant benefit [13]. Roth et al. published in 2007 the results of a phase II trial among 121 patients. Patients were randomised between docetaxel +cisplatin+5FU (DCF) and ECF. The regimen containing

DCF seemed to be more effective than ECF. DCF had shorter time-to-response, which may suggest that DCF is more favourable as preoperative treatment compared to ECF. However, DCF showed a trend towards increased myelosuppression and infectious complications [12]. Van Deenen et al. published in 2015 the results of a phase Ia/Ib trial of DOC in patients with advanced cancer of the stomach/GOJ. The data showed that the combination of intravenous docetaxel 50 mg/m² and oxaliplatin 100 mg/m² on day 1 plus capecitabine 850 mg/m² b.i.d. for 14 days in 3-week cycles were safe, tolerable and effective [15]. Toxicities among 28 patients were frequent, as is often the case in triple CT regimen, but remained non-severe and well manageable in most patients. The most common grade ≥ 3 toxicities were leukocytopenia (15%) and neutropenia (24%). Febrile neutropenia occurred in 12% of the patients, which is less than the 29% reported for the combination of DCF, reported by van Cutsem et al. [25].

Recently, the results of the FLOT4-AIO have been presented at the American Society of Clinical Oncology annual meeting [14]. In this study, patients with resectable gastric cancer or GOJ cancer, were randomised between perioperative CT with ECF/ECX versus fluorouracil+leucovorin+oxaliplatin+docetaxel (FLOT). Perioperative CT with ECF/ECX contained three pre- and postoperative cycles and perioperative CT with FLOT contained four pre- and postoperative cycles. Survival rates were significantly improved in the FLOT arm. This study showed significantly improved survival rates in the FLOT arm. Once the key-publication is available, it is expected that European guidelines will be updated. Various Dutch centres have already implemented the FLOT-regimen as standard perioperative CT. The CT regimen used in the CRITCS-II trial is a slight variation of FLOT, and the results of the FLOT4-AIO study support the use of DOC as preoperative CT in our study.

So far, this is the third randomised controlled trial in which patients with upper GI cancer are treated with preoperative CRT. The CROSS study forms the basis for the chosen CRT schedule [16]. One of the main concerns of preoperative CRT is the potential increased risk for surgical complications such as anastomotic leakage. The CROSS study showed no difference in postoperative complication rate between preoperative CRT and surgery alone [16]. Currently, the TOPGEAR study is recruiting patients. In this study, patients with resectable gastric or GOJ cancer are 1:1 randomised to receive either preoperative CT or preoperative CT followed by CRT, then followed by surgery and postoperative CT [26]. Recently, the interim analysis of the TOPGEAR trial has been published, which included a total of 120 patients. It revealed no difference in surgical complications between both groups [27]. A retrospective analysis from a prospectively maintained database from the *MD Anderson Cancer Center* was published in 2017. This analysis

included a total of 346 patients with resectable gastric cancer, of whom 44% underwent preoperative CRT [28]. No significant association between type of preoperative therapy and the risk of anastomotic leakage was found.

Future perspectives

The aim of this study is to select the most promising preoperative treatment regimen among three experimental arms in patients with resectable gastric adenocarcinoma. This treatment regimen will subsequently be compared with the current standard therapy in a phase III trial.

Funding

The study is funded by the Dutch Cancer Society. This funding source has no role in study design, data collection, analysis, interpretation, writing of the manuscript, or the decision to submit the current study.

Authors' contributions

EPMJ, HWMvL, JWvS, NCTvG, KS, AC, PMT, MCCMH, HB, ML, LVB, FPJP, GAPH, BvE, HHH, MlvBH, GAPN, RvH, DLvdP, HIG, and MV have made substantial contributions to conception and design of the trial. All authors are making substantial contributions to acquisition of data and in the analysis and interpretation of the data. All authors have given final approval for the submitted manuscript. All authors agreed to be accountable for all aspects of the work and in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Ethics approval and consent to participate

This study is conducted in agreement with either the Declaration of Helsinki or the laws and regulations of the country, whichever provides the greatest protection of the patient. The protocol has been written, and the study is conducted according to the ICH Harmonized Tripartite Guideline for Good Clinical Practice. The CRITCS-II trial has been approved by the medical ethics committee of the Antoni van Leeuwenhoek, Amsterdam. Patients receive both oral and written information about the study. Written informed consent will be obtained before any study procedures. Most recent protocol version is version 3.1 and was approved by the medical ethics committee at 18 April 2018. The sponsor/investigator has a liability insurance that provides cover for manage to research subjects through injury or death caused by the study. The insurance applies to the damage that becomes apparent during the study or within 4 years after the end of the study.
