Summary

Cryoelectron microscopy has been used to determine the first structure of a virus when complexed with its glycoprotein cellular receptor. Human rhinovirus 16 (HRV16) complexed with the two amino-terminal, immunoglobulin-like domains of the intercellular adhesion molecule-1 (ICAM-1) shows that ICAM-1 binds into the 12 Å deep “canyon” on the surface of the virus. This is consistent with the prediction that the viral receptor attachment site lies in a cavity inaccessible to the host's antibodies. The atomic structures of HRV14 and CD4, homologous to HRV16 and ICAM-1, showed excellent correspondence with observed density, thus establishing the virus-receptor interactions.

Introduction

Human rhinoviruses are one of the major causes of the common cold. They, like other picornaviruses, are icosahedral assemblies of 60 protomers that envelope a single, positive-sense strand of RNA. Each protomer consists of four polypeptides, VP1–VP4. The three external viral proteins (VP1–VP3) each have an approximate molecular weight of 30 000 and a similar folding topology [12, 29]. The external viral radius is ~150 Å and the total molecular weight is roughly 8.5×10^6 . A surface depression, or canyon, that is about 12 Å deep and 12–15 Å wide, encircles each pentagonal vertex (Fig. 1c). Residues lining the canyon are more conserved than other surface residues among rhinovirus serotypes [28]. The most variable surface residues are at the sites of attachment of neutralizing antibodies [29, 31]. It has been proposed that the cellular receptor molecule recognized by the virus binds to conserved residues in the canyon, thus escaping neutralization by host antibodies that are too big to penetrate into that region. This hypothesis [27, 29] is supported by site-directed mutagenesis of residues lining the canyon which alters the ability of the virus to attach to HeLa cell membranes [5]. Also, conformational changes in the floor of the canyon, produced by certain antiviral agents that bind into a pocket beneath the canyon floor, inhibit viral attachment to cellular membranes [26]. Conservation of the viral attachment site inside

a surface depression has been observed for Mengo [14] and influenza virus [38]. On the other hand, Yeates et al. [40] suggest that for a mouse adapted poliovirus, which has ~36% amino acid identity in VP1, the canyon hypothesis may not be applicable.

There are well over 100 human rhinovirus serotypes, which can be divided into roughly two groups according to the cellular receptor they recognize [1]. The structures of human rhinovirus 14 (HRV14) [29] and HRV16 [25a], which belong to the major group of serotypes, and of HRV1A [13], which belongs to the minor group of serotypes, have been determined. There are at least 78 serotypes [36] that bind to intercellular adhesion molecule-1 (ICAM-1), the major group rhinovirus receptor [10, 34]. The ICAM-1 molecule has five immunoglobulin-like domains (D1 to D5 numbered sequentially from the amino end), a transmembrane portion, and a small cytoplasmic domain [33]. Domains D2, D3 and D4 are glycosylated. Unlike immunoglobulins, ICAM-1 appears to be monomeric [34]. Mutational analysis of ICAM-1 has shown that domain D1 contains the primary binding site for rhinoviruses as well as the binding site for its natural ligand, lymphocyte function-associated antigen-1 (LFA-1) [20, 23, 35]. Other surface antigens within the immunoglobulin superfamily that are utilized by viruses as receptors include CD4 for human immunodeficiency virus-1 [6, 15], the poliovirus receptor [25], and the mouse coronavirus receptor [39]. In ICAM-1, in the poliovirus receptor [8, 16], and in CD4 [2] the primary receptor-virus binding site is domain D1. The structures of the two amino-terminal domains of CD4 have been determined to atomic resolution [30, 37]. Truncated proteins corresponding to the two amino-terminal domains of ICAM-1 (tICAM-1(185)) as well as the intact extracellular portion of ICAM-1 (tICAM-1(453) or domains D1 to D5) have been expressed in CHO cells [11]. The desialated form of tICAM-1(185), which will be referred to hereafter as molecule D1D2, has recently been crystallized [17].

The attachment of rhinovirus to the receptor molecule at the cell surface is only the first step of virus uncoating. Subsequent to binding receptor, virus is apparently internalized by receptor-mediated endo-cytosis and enters the endosomal compartment. Productive rhinovirus uncoating and infection requires an intracellular low pH step [21]. In vitro, low pH treatment will convert rhinovirus to both 135S (missing VP4) and 80S (missing VP4 and RNA) subviral particles [18]. A number of studies have shown that poliovirus can be conformationally altered to a 135S form upon interaction with its receptor, and rhinovirus can be converted to an 80S empty capsid by incubation in the presence of soluble ICAM-1 [11]. Thus, both virus-receptor binding and low pH (presumably in the endosomal compartment) appear to play active roles in the controlled disassembly of virus during uncoating, although the relative contributions of these two factors and their temporal relationship in vivo are unclear.

A model of the amino-terminal domain D1 of ICAM-1, based on its homology to known structures of the constant domains of immunoglobulins, was reported by Giranda et al. [9]. Guided by mutational studies of HRV14 and ICAM-1, they were able to fit this model into the known canyon structure of HRV14. We have utilized cryoelectron microscopy and image analysis techniques to calculate a three-dimensional reconstruction of the complex of HRV16 and D1D2 to ~28 Å resolution. The reconstruction clearly shows that the receptor binds into the canyon of rhinovirus as predicted [27, 29]. In addition, we use the known

structures of HRV14 and CD4 and the predicted structure of D1 of ICAM-1 to identify atomic interactions.

Structure of the virus: receptor model

Complexes between HRV16 and ICAM-1 D1D2 were prepared by incubating a 3.3 mg/ml solution of HRV16 with a 6.6 mg/ml solution of D1D2 for ~16 hours at 34°C. Under these conditions, saturated complexes of HRV16 with D1D2 can be generated, with approximately 60 moles of D1D2 per mole of virus. HRV14 could also form complexes, although these rapidly broke down to empty capsids (Hoover-Litty and Greve, in prep.) and electron micrographs of such specimens revealed severely disrupted particles in a background of protein. HRV16 complexes with D1D2 or with the complete D1 to D5 extracellular domain fragment were both used in the investigation. We present here only the results obtained on the HRV16:D1D2 complex.

Forty-four electron micrograph images for unstained HRV16:D1D2 complex were combined to compute a three-dimensional reconstruction (Fig. 1d) with an effective resolution of ~28 Å [3]. The density value of the D1D2 feature in the reconstruction was roughly the same as the density of the virion capsid, thus indicating that the D1D2 molecules nearly saturated the 60 available sites on the virion. The position of the ICAM relative to the icosahedral symmetry axes of the virus is unambiguous. Each D1D2 molecule has an approximate dumbbell shape, consistent with the presence of a two-domain structure.

A difference map between the EM model and the 20 Å HRV14 model was computed (Fig. 2). The difference map showed that the D1D2 molecule binds to the central portion of the canyon in a manner roughly as predicted by Giranda et al. [9], confirming the predictions inherent in the canyon hypothesis [27]. The D1D2 molecule is closely associated with the “southern” (see Fig. 3) wall and rim of the canyon, extending 10 Å to 12 Å into the canyon. The binding site is near the center of the triangle formed between a fivefold and two adjacent threefold axes (Fig. 3). The ICAM fragment is oriented roughly perpendicular to the viral surface and extends to a radius of ~205 Å. Its total length is ~75 Å as measured in the difference map.

Studies with interspecies chimeras and site-directed mutagenesis of ICAM-1 aimed at identifying the regions necessary for rhinovirus binding indicated that only the first domain is essential, and that the residues most involved in virus binding were concentrated on the outside end of domain D1 [23, 25]. However, it has proven difficult to produce an active form of domain D1 in solution, domains D1 + D2 being the minimal soluble virus-binding species [11]. The inability to produce domain D1 in isolation and the sequence alignment between ICAM-1 and CD4 suggested that domains D1 and D2 of ICAM-1 are intimately associated through a common, extended β -strand as is seen in the structure of CD4 [30, 37]. Thus, it seemed reasonable to use the known structures of CD4 for fitting the reconstructed density map (Fig. 2), although there was slightly too little density for domain D1 and too much density for D2. A better assessment of the fit of domain D1 to the density was obtained by taking the predicted D1 structure of ICAM-1, including all side chains, and superimposing it onto the fitted C_{α} backbone of CD4. One major difference is that although

domain D1 of CD4 resembles a variable, immunoglobulin-like domain with two extra β -strands, the ICAM-1 prediction is based on a more likely analogy to an immunoglobulin constant domain. This gives domain D1 of ICAM-1 a sleeker appearance, consistent with the observed difference density (Fig. 2a). The extra density in D2 (in the region furthest away from the virus (Fig. 2a)) compared to D2 of CD4 is probably due to the associated carbohydrate groups that are located in this region.

The atomic structure of HRV14 closely matched the reconstructed density that was not occupied by the D1D2 fragment. The only exception occurred in the BC loop of VP1 of HRV14 (see Fig. 2), which extended about 3 Å outside the reconstructed density on the “northern” rim of the canyon. However, this region of the polypeptide chain is a highly variable structure and is the site of one of the two largest conformational differences between HRV14 and HRV1A [10]. Furthermore, it is also the site of major differences in the structures of homologous poliovirus serotypes 1 and 3 [7].

We describe here the first structure of a virus-receptor complex in which the receptor is a membrane-bound glycoprotein molecule that is used by a virus for recognition of a specific host tissue for attachment and subsequent entry. This receptor molecule belongs to the immunoglobulin superfamily, a class of molecule frequently employed on cell surfaces for the recognition of other molecules (or recognized by viruses) that are subsequently transferred across the membrane.

Since the general nature of the complex described here had been predicted on the basis of the strategy used by HRV to hide its receptor attachment site, perhaps many other viruses use a similar strategy. Poliovirus is clearly homologous to HRV, and both poliovirus [25] and the major rhinovirus group use an immunoglobulin-like molecule as receptor. Thus, it would be expected that the poliovirus receptor binds into the poliovirus canyon in a manner similar to that of the complex formed for rhinoviruses [8]. The structure of a mouse-adapted chimera of human poliovirus 2 has been determined [40]. The major structural change occurs in the chimera in the BC loop, not in the canyon floor. In this instance, therefore, the BC loop might modulate the virus-receptor interaction. Knowledge of the virus-receptor interaction will illuminate various strategies currently being developed to interfere with early stages of rhinoviral and other viral infections [11, 22, 24].

Acknowledgments

We are grateful for many helpful discussions with R. Rueckert (University of Wisconsin) and M. McKinlay, F. Dutko, G. Diana and D. Pevear (Sterling Winthrop Pharmaceuticals Research Division). We are grateful to M. Kremer, C. Forte, and C. Music for technical assistance. We thank W. Hendrickson and S. Harrison for sharing coordinate information. We also thank H. Prongay and S. Wilder for help in preparation of this manuscript. The work was supported by National Institutes of Health grants to M.G.R. and to T.S.B., a National Science Foundation grant to T.S.B. and a Lucille P. Markey Foundation Award.
