Deaths: Final Data for 2002

by Kenneth D. Kochanek, M.A., Sherry L. Murphy, B.S.,
Robert N. Anderson, Ph.D., and Chester Scott, Division of Vital Statistics

Abstract

Objectives—This report presents final 2002 data on U.S. deaths and death rates according to demographic and medical characteristics such as age, sex, Hispanic origin, race, marital status, educational attainment, injury at work, State of residence, and cause of death. Trends and patterns in general mortality, life expectancy, and infant and maternal mortality are also described. A previous report presented preliminary mortality data for 2002.

Methods—In 2002 a total of 2,443,387 deaths were reported in the United States. This report presents descriptive tabulations of information reported on the death certificates. Funeral directors, attending physicians, medical examiners, and coroners complete death certificates. Original records are filed in the State registration offices. Statistical information is compiled into a national database through the Vital Statistics Cooperative Program of the National Center for Health Statistics (NCHS), Centers for Disease Control and Prevention. Causes of death are processed in accordance with the *International Classification of Diseases Tenth Revision* (ICD-10).

Results—The age-adjusted death rate for the United States in 2002 was 845.3 deaths per 100,000 standard population, representing a decrease of 1.1 percent from the 2001 rate and a record-low historical figure. Life expectancy at birth rose by 0.1-year to a record high of 77.3 years. Considering all deaths, age-specific death rates rose only for those under 1 year, and declined for a number of age groups including those 1–4 years, 25–34 years, 55–64 years, 65–74 years, 75–84 years, and 85 years and over. The 15 leading causes of death in 2002 remained the same as in 2001. Heart disease and cancer continued to be the leading and second leading causes of death, together accounting for over half of all deaths. The infant mortality rate in 2002 increased to 7.0 compared with a rate of 6.8 in 2001.

Conclusions—Generally, mortality patterns in 2002 were consistent with long-term trends. Life expectancy in 2002 increased again to a new record level. The age-adjusted death rate declined to a record low historical figure. However, the infant mortality rate increased in 2002. The infant mortality rate has either decreased or remained level each successive year through 2001 since 1958.

Trends for homicide and injury at work were interrupted due to the terrorist deaths that occurred September 11, 2001. The homicide rate decreased significantly from 2001 to 2002 and dropped to the 14th leading cause of death. Deaths due to injury at work also declined significantly during this period.

Keywords: deaths • mortality • cause of death • life expectancy • vital statistics • ICD-10

Highlights

Mortality experience in 2002

- In 2002 a total of 2,443,387 deaths occurred in the United States.
- The age-adjusted death rate, which eliminates the effects of the aging of the population, was 845.3 deaths per 100,000 U.S. standard population.

Acknowledgments

This report was prepared under the general direction of Charles J. Rothwell, Director of the Division of Vital Statistics (DVS), James A. Weed, Deputy Director of DVS, and Robert N. Anderson, Chief, Mortality Statistics Branch (MSB). Nicholas F. Pace, Chief of the Systems, Programming and Statistical Resources Branch (SPSRB), and Gail A. Parr, Steven J. Steimel, Jordan A. Sacks, Manju Sharma, Jaleh Mousavi, Candace Cosgrove and John Birken provided computer programming support. Elizabeth Arias of MSB provided content related to life expectancy. Robert N. Anderson and Sherry L. Murphy of MSB, David W. Justice of the Data Acquisition and Evaluation Branch, and Van L. Parsons of the Office of Research and Methodology contributed to the "Technical Notes." Thomas D. Dunn of SPSRB provided statistical tables and content review. JoAnn Wiley and Betty L. Smith of MSB provided content and table review. The Registration Methods staff and staff of the Data Acquisition and Evaluation Branch of DVS provided consultation to State vital statistics offices regarding collection of the death certificate data on which this report is based. This report was edited by Thelma Sanders, typeset by Jacqueline M. Davis, and the graphics produced by Jarmila G. Ogburn of the Information Design and Publishing Staff, Office of Information Services.

- Life expectancy at birth was 77.3 years.
- The 15 leading causes of death in 2002 were as follows:
 - Diseases of heart (heart disease)
 - Malignant neoplasms (cancer)
 - Cerebrovascular diseases (stroke)
 - Chronic lower respiratory diseases
 - Accidents (unintentional injuries)
 - Diabetes mellitus (diabetes)
 - Influenza and pneumonia
 - Alzheimer's disease
 - Nephritis, nephrotic syndrome and nephrosis (kidney disease)
 - Septicemia
 - Intentional self-harm (suicide)
 - Chronic liver disease and cirrhosis
 - Essential (primary) hypertension and hypertensive renal disease (hypertension)
 - Assault (homicide)
 - Pneumonitis due to solids and liquids
- In 2002 the infant mortality rate was 7.0 infant deaths per 1,000 live births.
- The 10 leading causes of infant death were as follows:
 - Congenital malformations, deformations, and chromosomal abnormalities (congenital malformations)
 - Disorders relating to short gestation and low birth weight, not elsewhere classified (low birth weight)
 - Sudden infant death syndrome (SIDS)
 - Newborn affected by maternal complications of pregnancy (maternal complications)
 - Newborn affected by complications of placenta, cord, and membranes (cord and placental complications)
 - Accidents (unintentional injuries)
 - Respiratory distress of newborn
 - Bacterial sepsis of newborn
 - Diseases of the circulatory system (circulatory diseases)
 - Intrauterine hypoxia and birth asphyxia

Trends

- The age-adjusted death rate in 2002 for the United States reached a record low.
- Life expectancy was 77.3 years, a record high that surpassed the previous highest value, recorded in 2001. Record high life expectancy was attained by the total population, as well as by the black and white populations. Both males and females in each of the two major race groups attained record high levels.
- Age-adjusted death rates decreased from 2001 to 2002 for 4 of the 15 leading causes of death and increased for 7 of the 15 leading causes of death. Decreasing trends for heart disease, cancer, and stroke, the three leading causes, continued. Increasing trends for Alzheimer's disease continued.
- Differences in mortality between men and women continued to narrow. The age-adjusted death rate for men was 42 percent greater than that for women (down from 43 percent greater in 2001), and life expectancy for men was shorter than that for women by 5.4 years, unchanged from 2001 but still at the lowest level recorded.

- Differences in mortality between the black and white populations persisted even though there was a trend toward convergence. The age-adjusted death rate was 1.3 times greater, the infant mortality rate 2.5 times greater, and maternal mortality rate 4.2 times greater for the black population than that for the white population. Life expectancy for the white population exceeded that for the black population by 5.4 years.
- The age-adjusted death rate due to poisonings increased by 17.9 percent from 2001 to 2002.
- Between 2001 and 2002 the age-adjusted death rate for drug-induced causes increased 18.4 percent.
- Infant mortality rate increased for the first time in over four decades in 2002.

Introduction

This report represents the release of final national mortality statistics for 2002 and presents detailed data on deaths and death rates according to a number of social, demographic, and medical characteristics. These data provide information on mortality patterns among Americans by such variables as age, sex, Hispanic origin, race, marital status, educational attainment, injury at work, State of residence, and cause of death. Information on these mortality patterns is important for understanding changes in the health and well-being of the U.S. population (1). Preliminary data for 2002 were presented in the report "Deaths: Preliminary Data for 2002" using a 96-percent (demographic file) sample of U.S. deaths weighted to independent control totals (2). The findings in this report, based on the final mortality file, are generally consistent with those based on preliminary data; the final mortality file incorporates some modifications to the preliminary file as described in the "[Technical Notes](#)." Separate companion reports present additional details on leading causes of death, injury-related deaths, and life expectancy in the United States (3–5).

Mortality data in this report can be used to monitor and evaluate the health status of the Nation in terms of current mortality levels and long-term mortality trends, as well as to identify segments of the U.S. population at greatest risk of death from specific diseases and injuries. Differences in death rates among demographic groups, including racial and ethnic groups, may reflect group differences in factors such as socioeconomic status, access to medical care, and the prevalence of risks specific to a particular group.

Methods

Data in this report are based on information from all resident death certificates filed in the 50 States and the District of Columbia. It is believed that more than 99 percent of deaths occurring in this country are registered (6). Tables showing data by State also provide information for Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Mariana Islands (Northern Marianas). Cause-of-death statistics presented in this report are classified in accordance with the *International Classification of Diseases, Tenth Revision*, (ICD-10) (7). (A discussion of the cause-of-death classification is provided in the "[Technical Notes](#).")

Mortality data on specific demographic and medical characteristics except educational attainment cover all 50 States and the District of Columbia. Educational attainment data are provided for 47 States and

the District of Columbia. Details on reporting areas for educational attainment are provided in the “[Technical Notes](#).”

Measures of mortality in this report include the number of deaths; crude, age-specific and age-adjusted death rates; infant, neonatal, postneonatal, and maternal mortality rates; life expectancy; and rate ratios. Changes in death rates from 2001 to 2002 and differences in death rates across demographic groups in 2002 are tested for statistical significance. Unless otherwise specified, reported differences are statistically significant. Additional information on these statistical methods, random variation and relative standard error, the computation of derived statistics and rates, population denominators, and the definition of terms is presented in the “[Technical Notes](#).”

The populations used to calculate death rates for 2001, 2002, and the intercensal period 1991–99 shown in this report were produced under a collaborative arrangement with the U.S. Census Bureau. Reflecting the new guidelines issued in 1997 by the Office of Management and Budget (OMB), the 2000 census included an option for individuals to report more than one race as appropriate for themselves and household members (8); see “[Technical Notes](#).” The 1997 OMB guidelines also provided for the reporting of Asian persons separately from Native Hawaiians or other Pacific Islanders. Under the prior OMB standards (issued in 1977), data for Asian or Pacific Islander persons were collected as a single group (9). Death certificates currently collect only one race for the decedent in the same categories as specified in the 1977 OMB guidelines (that is, death certificate data do not report Asians separately from Native Hawaiians or other Pacific Islanders). Death certificate data by race (the numerators for death rates) are thus currently incompatible with the population data collected in the 2000 census (the denominators for the rates). To produce death rates for 2001, 2002, and revised intercensal rates for 1991–99, it was necessary to “bridge” the reported population data for multiple race persons back to single race categories. In addition, the 2000 census counts were modified to be consistent with the 1977 OMB race categories, that is, to report the data for Asian persons and Native Hawaiians or other Pacific Islanders as a combined category, Asian or Pacific Islanders, and to reflect age as of the census reference data (10). The procedures

used to produce the “bridged” populations are described in separate publications (11,12). It is anticipated that “bridged” population data will be used over the next few years for computing population-based rates. Beginning with deaths occurring in 2003, some States will use multiple race reporting. As States gradually begin to collect data on race according to the 1997 OMB guidelines, it is expected that use of the bridged populations will be discontinued.

Readers should keep in mind that the population data used to compile death rates by race shown in this report are based on special estimation procedures. They are not true counts. This is the case even for the 2000 populations that are based on the 2000 census. The estimation procedures used to develop these populations contain some error. Smaller population groups are affected much more than larger populations (11). Over the next several years, additional information will be incorporated in the estimation procedures, possibly resulting in further revisions of the population estimates (see “[Technical Notes](#)”).

Data in this report are based in part on unpublished work tables. These and other data are available on the NCHS Web site, at www.cdc.gov/nchs/about/major/dvs/mortdata.htm, and on the forthcoming CD-ROM entitled, *Vital Statistics of the United States, Mortality, 2002*. Availability of mortality microdata is described in the “[Technical Notes](#)” of this report.

Results and Discussion

Deaths and death rates

In 2002 a total of 2,443,387 resident deaths were registered in the United States, 26,962 more than in 2001. The crude death rate for 2002, 847.3 deaths per 100,000 population, was 0.1 percent lower than the 2001 rate (848.5) ([tables 1](#) and [A](#)).

The age-adjusted death rate in 2002 was 845.3 deaths per 100,000 U.S. standard population, a record low value that was 1.1 percent lower than the 2001 rate of 854.5 ([tables 1](#) and [A](#)). Age-adjusted death rates are constructs that show what the level of mortality would be if no changes occurred in the age composition of the population from

²Death rates for “Under 1 year” (based on population estimates) differ from infant mortality rates (based on live births).

year to year. (For a discussion of age-adjusted death rates, see “[Technical Notes](#).”) Thus, the age-adjusted death rates are better indicators than unadjusted (crude) death rates for examining changes in the risk of death over a period of time when the age distribution of the population is changing. Also, age-adjusted death rates are better indicators of relative risk when comparing mortality across geographic areas or between sex or race subgroups of the population that have different age compositions. Since 1980 the age-adjusted death rate has decreased every year except 1983, 1985, 1988, 1993, and 1999. These were years when influenza outbreaks contributed to increased mortality in the United States (13–15). Despite an influenza outbreak in the beginning of 2002 (16) and an increase in the total number of deaths, the age-adjusted death rate did not increase in 2002. Between 1980 and 2002 the age-adjusted death rate declined 18.7 percent ([figure 1](#) and [table 1](#)).

Race—The 2002 age-adjusted death rates for the major race groups were as follows: the rate for the white population was 829.0 deaths per 100,000 U.S. standard population; black population, 1,083.3; American Indian population, 677.4; and Asian or Pacific Islander population, 474.4 ([table 1](#)). Rates for the American Indian and Asian or Pacific Islander populations should be interpreted with caution because of reporting problems on both the death certificate and in population censuses and surveys. The net effect of the reporting problems is for the American Indian rate to be approximately 21 percent understated and the Asian or Pacific Islander rate to be approximately 11 percent understated (17).

In 2002 the age-adjusted death rate for the black population was 1.3 times that for the white population ([table C](#)); that is, the average risk of death for the black population was about 31 percent higher than for the white population. This ratio was the same in 2001. Between 1960 and 1982, rates for the black and white populations declined by similar percentages (22.6 and 26.5 percent, respectively). For the period ranging from 1982 to 1988 rates diverged (18), increasing 5.2 percent for the black population and decreasing 1.7 percent for the white population. The disparity in age-adjusted death rates between the black and white populations reached its highest point in 1989. Since then, rates for the black and white populations have tended toward convergence, declining by 15.1 percent for the black population and by 9.9 percent for the white population.

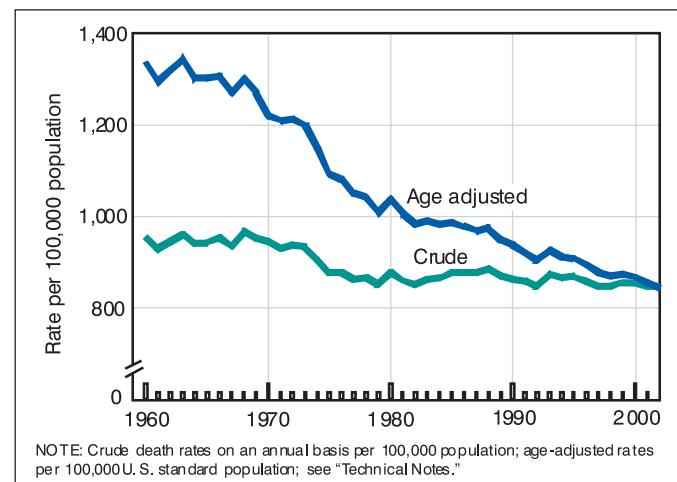

Figure 1. Crude and age-adjusted death rates: United States, 1960–2002

Between 2001 and 2002 decreases in age-adjusted death rates were observed for both white males and females and for both black males and females. In order of relative magnitude of decrease from 2001, the reductions were 2.4 percent for black males, 1.3 percent for white males, 1.2 percent for black females, and 0.8 percent for white females ([tables A](#) and [1](#)).

Age-adjusted death rates have generally declined between 1980 and 2002 for white males and females. However, increases were observed for both white males and white females in 1983, 1985, 1988, and 1993. In addition, the age-adjusted death rate for white females increased in 1995 and 1999. For black males, age-adjusted death rates tended to decrease except for a period of increase between 1983 and 1988; rates for black females decreased between 1980 and 2002, although with considerable variability in direction of change from year to year ([table 1](#)).

Hispanic origin—Problems of race and Hispanic-origin classification affect Hispanic death rates and the comparison of rates for the Hispanic and the non-Hispanic population (see “[Technical Notes](#)”). Mortality for Hispanics is somewhat understated because of net under-reporting of Hispanic origin on the death certificate. Hispanic origin on the death certificate is underreported by an estimated 7 percent (17) (see “[Technical Notes](#)”). Mitigating this somewhat is undercoverage of the Hispanic population in the census and in annual population estimates based on the census (17). The age-adjusted death rate for the Hispanic population in 2002 was 629.3, decreasing by 4.5 percent from the rate of 658.7 observed in 2001 ([tables B](#) and [2](#)). Total non-Hispanic and non-Hispanic white populations experienced significant decreases, ranging from 0.9 to 0.6 percent, respectively. The non-Hispanic black population also experienced significant decline in the age-adjusted death rate from the previous year.

Among Hispanic males, the age-adjusted death rate declined by 4.5 percent between 2001 and 2002, and the rate for Hispanic females declined by 4.8 percent. Non-Hispanic white males and non-Hispanic black males experienced declines in the age-adjusted death rate of 1.0 and 2.4 percent, respectively. Similarly, non-Hispanic white and non-Hispanic black females experienced declines of 0.5 and 1.1 percent, respectively ([tables B](#) and [2](#)).

In 2002 the age-adjusted death rate ([table 2](#)) was 26.5 percent lower for the Hispanic population than for the non-Hispanic population. It was similarly 24.9 percent lower than the rate for the non-Hispanic white population and considerably lower (43 percent) than the rate for the non-Hispanic black population. The large differences in mortality between the Hispanic and non-Hispanic populations are partly a function of the Hispanic population’s lower age-specific death rates at older ages ([table 4](#)). Part of the difference is also attributable to under-reporting of Hispanic origin on the death certificate. In addition, there are various hypotheses that have been proposed to explain Hispanic’s favorable mortality outcomes. The most prevalent hypotheses include the healthy migrant effect, which argues that Hispanic immigrants are selected for their good health and robustness; and, the salmon bias effect, which posits that U.S. residents of Hispanic origin may return to their country of origin to die or when ill (19).

Within the Hispanic population, the age-adjusted death rate for males was 1.5 times that for females ([table 2](#)). The male-to-female ratio of age-specific death rates differed substantially by age, with Hispanic males experiencing rates more than 2 times those for Hispanic females for three age groups in the range 15–44 years. The ratio ranged

Table B. Percent change in death rates and age-adjusted death rates between 2001 and 2002 by age, Hispanic origin, race for non-Hispanic population, and sex: United States

[Age-adjusted death rates per 100,000 U.S. standard population. Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race. Data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes"]

¹Rank based on number of deaths; see "Technical Notes."

between 1.3 and 1.4 for defined age groups under 15 years and between 1.9 and 1.1 for ages 45 years and over (table 5).

The age-adjusted death rates in 2002 for selected Hispanic subgroups, in order of relative magnitude, were as follows: 766.2 deaths

per 100,000 U.S. standard population for the Puerto Rican population; 761.8 for the Other Hispanic population, combined; 612.8 for the population of Mexican origin, and 524.1 for the population of Cuban origin (table 5). The only statistically significant difference between the

various Hispanic subgroups was that between the Puerto Rican and Cuban populations. Puerto Ricans had a significantly higher age-adjusted death rate than the Cuban origin population. The lack of statistical significance for all other possible combinations of subgroup differentials, especially between the remaining subgroups and the Puerto Rican population, is likely a function of large statistical variation in age-specific death rates for some of the Hispanic subgroups, reflecting their relatively small population sizes. Studies that aggregate data over several years do confirm differences among most Hispanic subgroups in mortality (20).

Death rates by age and sex

Between 2001 and 2002 age-specific death rates for the total population decreased for age groups 1–4 years, 25–34 years, 55–64 years, 65–74 years, 75–84 years, and 85 years and over, but increased for the age group under 1 year (see also Infant mortality) (table A and figure 2). The largest drop in age-specific death rates in 2002 occurred among the age group 1–4 years (6.3 percent). The only increase was for the age group under 1 year (1.7 percent).

The death rates for males declined between 2001 and 2002 for age groups 55–64 years, 65–74 years, 75–84 years, and 85 years and over. There were no significant increases in age-specific death rates for males. The largest decrease for males occurred for age group 85

years and over (2.9 percent). For females, death rates declined for age groups 1–4 years, 25–34 years, 55–64 years, 65–74 years, and 85 years and over. There were no significant increases in age-specific death rates for females. The largest drop in the age-specific rates occurred for females 1–4 years of age (8.5 percent).

Race—Age-specific death rates declined for white males for the following age groups in 2002: 1–4 years, 65–74 years, 75–84 years, and 85 years and over. Increases in the age-specific death rate for the white male population occurred in the age group under 1 year (3.7 percent). The largest decrease was for the age group 1–4 years (7.9 percent). The black male population in 2002 showed mostly decreasing trends in mortality when considering age. Significant declines were noted for the following age groups: under 1 year, 15–24 years, 65–74 years, 75–84 years, and 85 years and over. The largest decrease was for the age group under 1 year (5.3 percent). For white females, the death rate decreased in 2002 for those aged 1–4 years, 25–34 years, 55–64 years, 65–74 years, and 85 years and over. The largest decrease was observed for the age group 1–4 years (9.6 percent). An increase was observed for the age group 15–24 years (3.9 percent). Age-specific rates for black females decreased for age groups 55–64 years and 65–74 years. The largest decrease was observed for the age group 65–74 years (2.7 percent). No significant increase in age-specific rates was found for this population.

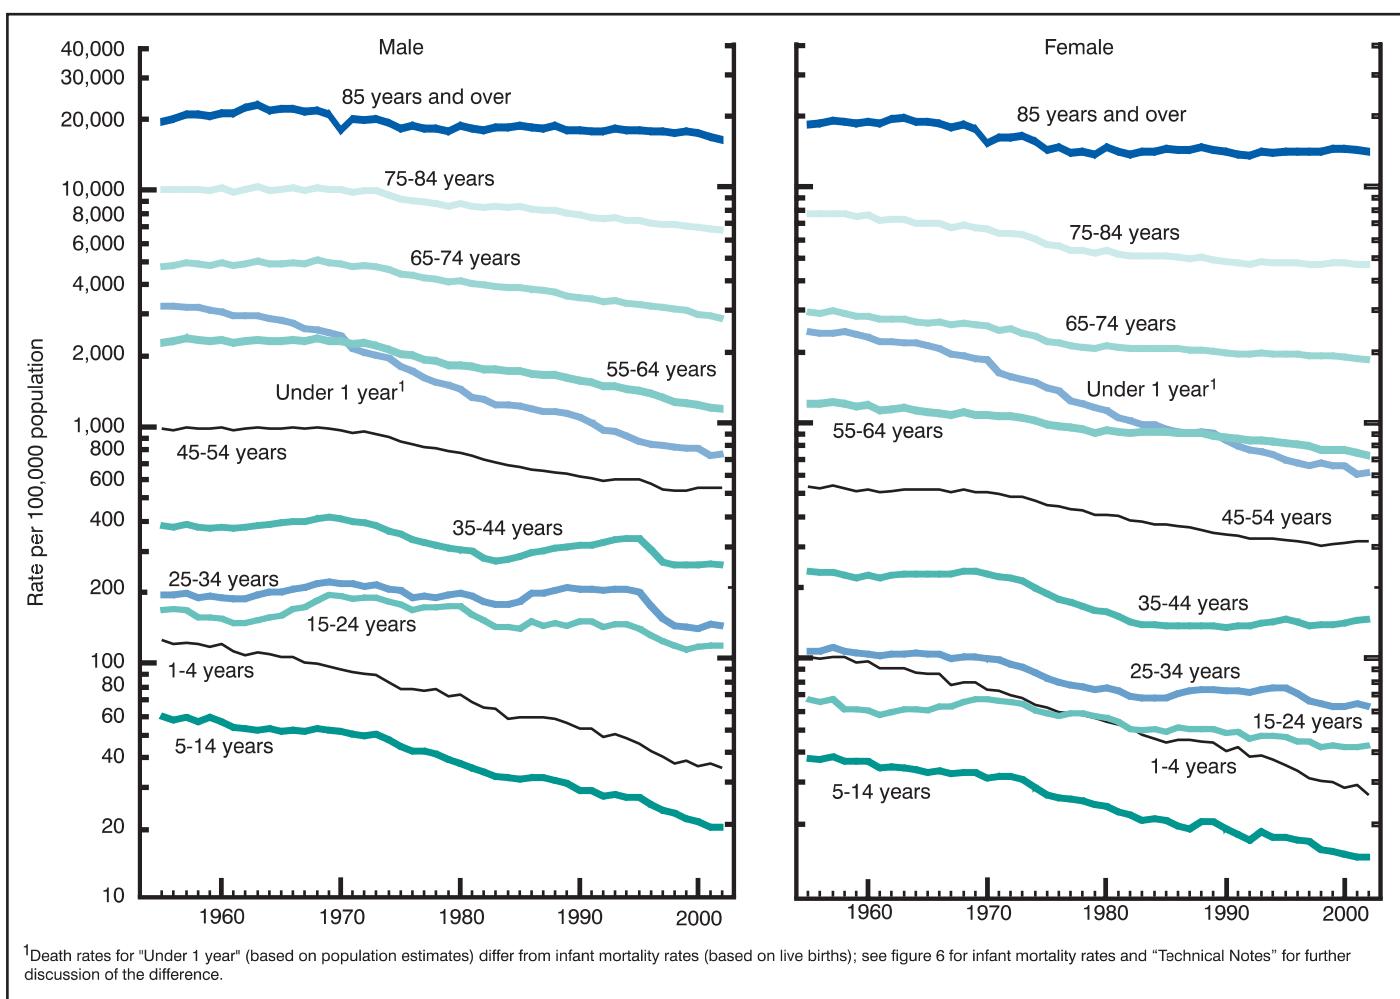

Figure 2. Death rates by age and sex: United States, 1955–2002

Hispanic origin—For the Hispanic origin population, the age-specific death rate declined significantly between 2001 and 2002 for age groups 25–34 years, 35–44 years, 45–54 years, 65–74 years, 75–84 years and 85 years and over (table B). Hispanic males showed decreases for age groups 25–34 years, 35–44 years, 45–54 years, 75–84 years and 85 years and over. For Hispanic females, those in the age groups 25–34 years and 85 years and over experienced a decline in age-specific death rates between 2001 and 2002. No statistically significant increase was observed for the total Hispanic population or for Hispanic males or females, for any age group. Mortality for Hispanics is somewhat understated because of net underreporting of Hispanic origin on the death certificate (17).

Expectation of life at birth and at specified ages

Life expectancy at birth represents the average number of years that a group of infants would live if the infants were to experience throughout life the age-specific death rates present at birth. The life table methodology used to calculate the life expectancies shown in this report was revised beginning with the 1997 data year (see “Technical Notes”). The revised methodology provides values similar to the method used before 1997, but is more comparable to decennial life table methods, provides more accurate estimates, and provides more age detail. In 2002 life expectancy at birth reached a record high of 77.3 years (tables 6–8), rising above the previous high of 77.2 years in 2001. The trend in the U.S. life expectancy since 1900 is one of gradual improvement.

In 2002 life expectancy for females was 79.9 years, a 0.1-year increase from 2001, and for males it was 74.5 years, also a 0.1-year increase from the previous year. Both attained record high life expectancy levels. From 1900 to the late 1970s, the sex gap in life expectancy widened (figure 3) from 2.0 years to 7.8 years. Since its peak in the 1970's, the sex gap has been narrowing (figure 3). The difference in life expectancy between the sexes remained at 5.4 years in 2002, the same as 2000 and 2001.

Between 2001 and 2002 life expectancy increased 0.1 year for the black population to a record high of 72.3 years. Life expectancy for the white population remained the same as in 2001, 77.7 years. The difference in life expectancy between the white and black populations in 2002 was 5.4 years, a 0.1-year decrease from the 2001 gap between the two races and the smallest gap ever recorded. The white-black difference in life expectancy reversed a long-term decline beginning in 1982 when the gap was 5.7 years. Between 1982 and 1989 the gap widened, reaching a peak difference of 7.1 years. Since 1989, the gap has been narrowing gradually to the current record low (figure 3).

Among the four major race-sex groups (tables 7 and 8, figure 4), white females continued to have the highest life expectancy at birth (80.3 years), followed by black females (75.6 years), white males (75.1 years), and black males (68.8 years). Record high life expectancies were reached by all four race-sex groups. Life expectancy for black males declined every year from 1984 to 1989 then resumed the long-term trend of increase from 1990 to 1992 and 1994 to 2002 (table 8). For white females life expectancy increased most years from 1970 to 1998. In 1999 life expectancy for white females fell below 1998's record high level, but in 2000 life expectancy for this population began again to rise. Between 1988 and 1992, 1993 and 1994, and between 1995 and 1998, life expectancy for black females increased. In 1999 life expectancy for black females declined as it did for white

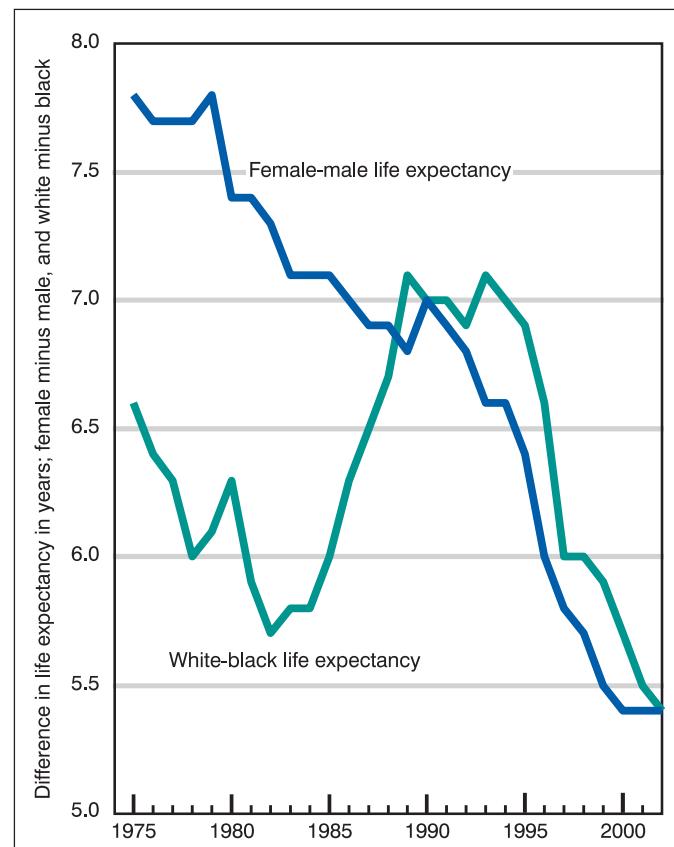

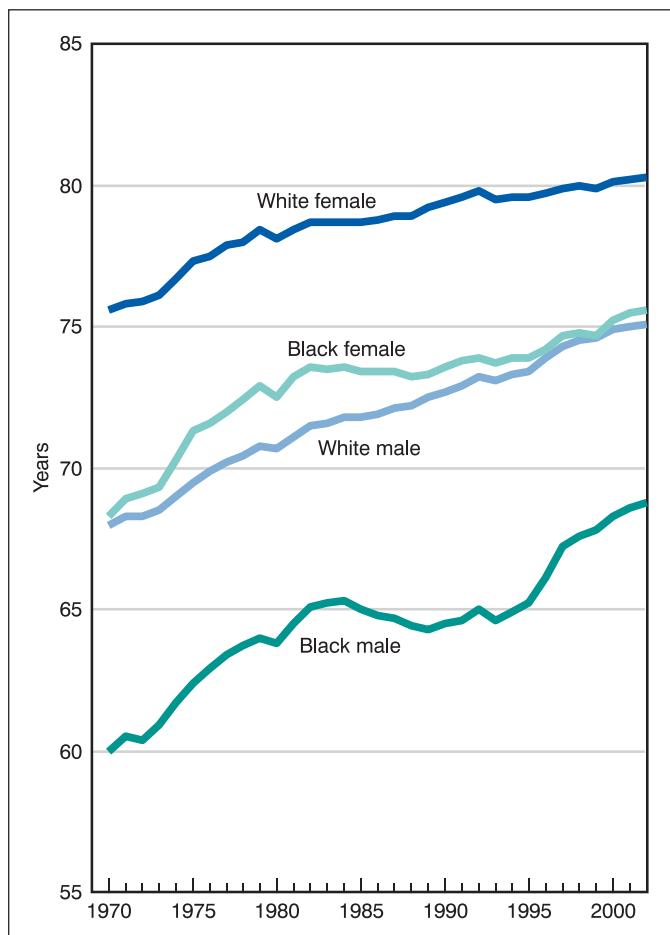

Figure 3. Difference in life expectancy between females and males, and between white and black: United States, 1975–2002

females, only to climb back up in 2000 to a record high number. Between 2001 and 2002 the largest gain in life expectancy was for black males (0.2 years).

Life tables shown in this report may be used to compare life expectancies at selected ages from birth to 100 years. For example, a person who has reached 65 years may hypothetically look forward to living to an older age, on the average, than one who has reached 50 years. On the basis of mortality experienced in 2002, a person aged 50 years could expect to live an average of 30.3 more years for a total of 80.3 years. A person aged 65 years could expect to live an average of 18.2 more years for a total of 83.2 years, and a person aged 85 years could expect to live an average of 6.5 more years for a total of 91.5 years (tables 6 and 7).

Leading causes of death

The 15 leading causes of death in 2002 accounted for 83.3 percent of all deaths in the United States (table C). Causes of death are ranked according to number of deaths. For ranking procedures, see “Technical Notes.” In order the 15 leading causes in 2002 were: 1) Diseases of heart (heart disease), 2) Malignant neoplasms (cancer), 3) Cerebrovascular diseases (stroke), 4) Chronic lower respiratory diseases, 5) Accidents (unintentional injuries), 6) Diabetes mellitus (diabetes), 7) Influenza and pneumonia, 8) Alzheimer's disease, 9) Nephritis, nephrotic syndrome and nephrosis (kidney disease), 10) Septicemia, 11) Intentional self-harm (suicide), 12) Chronic liver disease and cirrhosis, 13) Essential (primary) hypertension and

**Figure 4. Life expectancy by race and sex:
United States, 1970–2002**

hypertensive renal disease (hypertension), 14) Assault (homicide), and 15) Pneumonitis due to solids and liquids.

The 15 leading causes of death in 2002 remained what they were in 2001, although homicide changed places with hypertension, returning to their positions in 2000 as the 14th and 13th leading causes of death, respectively. In 2001 homicide rose in rank to 13th due to the addition of deaths that resulted from the September 11, 2001, terrorist attacks.

Individuals and agencies tracking ranking and trend data of leading causes of deaths need to note the recent introduction of a new cause-of-death classification system starting with 1999 data. The changes in the classification of diseases between ICD-9 and ICD-10 and the new coding rules for selecting the underlying cause of death (see section on Tabulation lists and cause-of-death ranking in “[Technical Notes](#)”) have had substantial impact on differences between trends from 1979 to 1998 and trends from 1999 on. Implementation of ICD-10 did not affect the ranking of the first five leading causes of death (21) but affected the ranking for diabetes, Influenza and pneumonia, Alzheimer’s disease, suicide, and Chronic liver disease and cirrhosis. Detailed information on the effects of the transition from ICD-9 to ICD-10 can be found in previous reports and documents issued by NCHS (21,22).

The age pattern of mortality can vary greatly by cause of death and as a result changes in crude death rates over time can be significantly influenced by the changing composition of the population.

In contrast, age-adjusted death rates eliminate the influence of such shifts in the population age structure. Therefore, age-adjusted death rates are better indicators than crude rates for showing changes in mortality risk over time and among causes of death. Consequently, age-adjusted rates are used to depict trends for leading causes of death even though the causes are ranked based on the number of deaths ([figure 5](#)).

Between 2001 and 2002 the age-adjusted death rate for all causes in the United States decreased by 1.1 percent. The actual number of deaths increased by 1.1 percent from 2001 (26,962 more deaths). This reduction in the risk of dying has been driven mostly by net decreases in such large-number causes as heart disease and stroke.

Among the leading causes of death, age-adjusted death rates decreased for 4 of the 15 leading causes between 2001 and 2002 ([table C](#)). The age-adjusted death rate for heart disease (the leading cause of death) declined by 2.8 percent. Except for a relatively small increase in 1993, mortality from heart disease has steadily declined since 1980. From 2001 to 2002 cancer mortality declined by 1.3 percent. The age-adjusted death rate for cancer, the second leading cause of death, has shown a gradual but consistent downward trend since 1993. The rate for stroke, the third leading cause of death, declined 2.9 percent between 2001 and 2002. Stroke has generally declined since 1958, with one exception, an increase of 2.6 percent between the years 1992 and 1995. The age-adjusted death rate for homicide (the 14th leading cause of death) decreased by 14.1 percent between 2001 and 2002. The dramatic decline in the homicide rate was primarily a result of the September 11, 2001, terrorist attacks, which added 2,926 certified resident deaths to this category in 2001. Without the additional deaths resulting from the terrorist attacks in 2001, the homicide rate would have remained the same between 2001 and 2002.

Age-adjusted death rates increased significantly for 7 of the 15 leading causes of death between 2001 and 2002. The age-adjusted death rate for unintentional injuries (the fifth leading cause of death) increased by 3.4 percent. Death rates for unintentional injuries decreased 28.6 percent during the period 1979–92, reaching its lowest point of 33.2 deaths per 100,000 standard population in 1992. Since then, however, the mortality trend for unintentional injuries has been one of gradual increase, rising by 3.9 percent between 1992 and 1998 and increasing 4.5 percent between 1999 and 2002. The age-adjusted death rate for Influenza and pneumonia (seventh leading cause of death) increased by 2.7 percent between 2001 and 2002. An influenza outbreak was reported in early 2002 (16). The rate for the eighth leading cause of death (Alzheimer’s disease) increased by 5.8 percent between 2001 and 2002. The trend for mortality due to Alzheimer’s disease has been one of rapid increase. From 1979 until 1998, the rate for Alzheimer’s disease increased dramatically due to improvements in diagnosis, awareness of the condition within the medical community, and other unidentified factors (23). The transition from ICD-9 to ICD-10 brought substantial changes to the coding and selection rules of this condition. This created a major disruption in the time series’ trend for Alzheimer’s disease between 1998 and 1999. The large increase between 1998 and 1999 may partly be a function of the ICD transition and evaluating the observed change poses a problem because the comparability ratio (that represents the net effect of the new revision on cause-of-death statistics) for Alzheimer’s disease may be understated (21,22). The death rate for kidney disease, the ninth leading cause of death, increased 1.4 percent in 2002. Kidney disease is another condition substantially affected by the transition from ICD-9 to

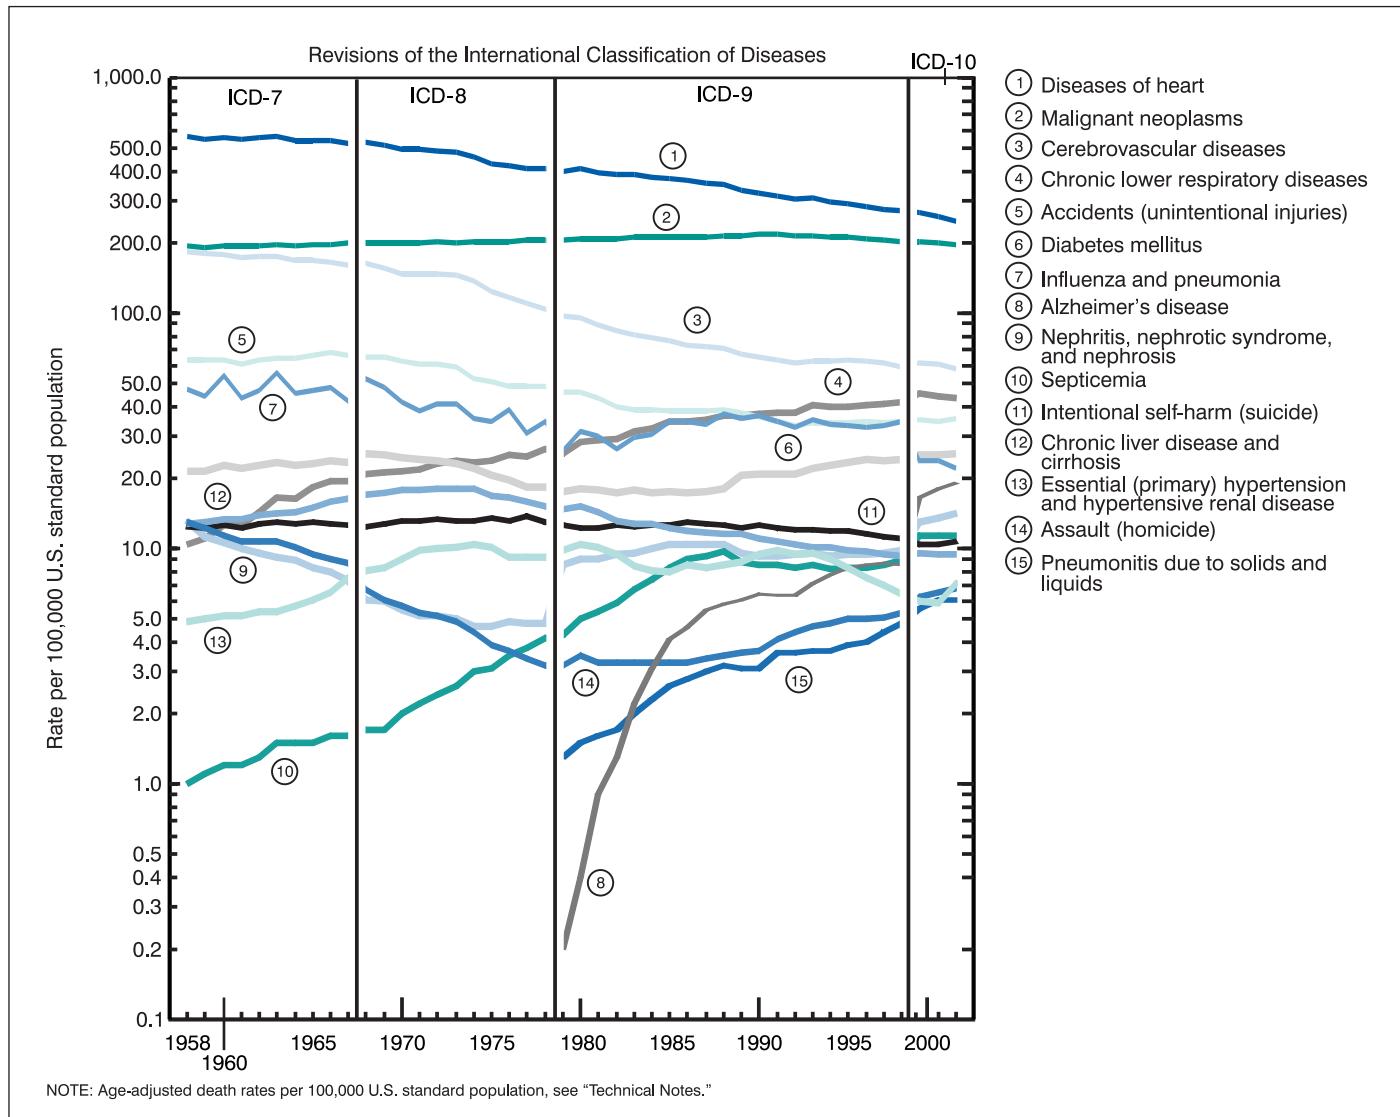

Figure 5. Age-adjusted death rates for the 15 leading causes of death: United States, 1958–2002

ICD-10. Thus, evaluating the observed change in the death rate for kidney disease between 1998 and 1999 is also complicated by a comparability ratio that may be understated (21,22). The age-adjusted death rate for Septicemia (10th leading cause of death) increased by 2.6 percent between 2001 and 2002. The age-adjusted death rate for suicide (11th leading cause of death) increased by 1.9 percent between 2001 and 2002. Steadily rising since 1987, the age-adjusted death rate for hypertension (the 13th leading cause) increased 2.9 percent from 2001 to 2002.

Even though mortality from Human immunodeficiency virus disease (HIV disease) has not been on the list of 15 leading causes of death since 1997 (24), it is still considered a major public health problem. In 2002 a total of 14,095 persons died from HIV disease. The age-adjusted death rate (4.9 per 100,000 standard population) declined for the seventh consecutive year, decreasing 2.0 percent from the rate in 2001. The rate of decline in mortality from this cause has slowed considerably and the death rate appears to be stabilizing.

Changes in mortality levels by age and cause of death have an important effect on changes in life expectancy. Life expectancy at birth increased between 2001 and 2002 by 0.1 year due to decreases in mortality from heart disease, cancer, homicide, stroke, and Chronic lower respiratory diseases. The increase in life expectancy could have been greater than 0.1 year if it were not for the increase in mortality from unintentional injuries, Alzheimer's disease, Influenza and pneumonia, Septicemia, and suicide. (For discussion of contributions to the change in life expectancy, see "Technical Notes.")

For males, life expectancy improved by 0.1 year from 74.4 years in 2001 to 74.5 years in 2002 primarily because of decreases in mortality from heart disease, homicide, cancer, stroke, and HIV disease. The increase in life expectancy for males could have been greater than 0.1 year were it not for the offsetting increases in mortality from unintentional injuries, diabetes, Septicemia, Certain conditions originating in the perinatal period (perinatal conditions) and Alzheimer's disease. For females, life expectancy increased by 0.1 year from 79.8

years in 2001 to 79.9 years in 2002 due to decreases in mortality from heart disease, cancer, homicide, stroke, and Chronic lower respiratory diseases. The increase in life expectancy for females could have been greater were it not for the offsetting effect of increases in mortality from unintentional injuries, Alzheimer's disease, Influenza and pneumonia, perinatal conditions and Septicemia.

The relative risk of death in one population group compared with another can be expressed as a ratio. Ratios based on age-adjusted death rates show that males have higher rates than females for 12 of the 15 leading causes of death ([table C](#)), with eight rates for males being at least 1.5 times those for females. The largest ratio (4.4) was for suicide. Other large ratios were evident for homicide (3.4), unintentional injuries (2.2), Chronic liver disease and cirrhosis (2.0), Pneumonitis due to solids and liquids (1.8), cancer, and heart disease (1.5 each).

The difference in life expectancy between males and females did not change between 2001 and 2002, remaining at 5.4 years. The absence of change in the difference between male and female life expectancy was a result of offsetting improvements in mortality from specific causes for males and females. For example, males experienced greater improvements in mortality from homicide, Alzheimer's disease, unintentional injuries, HIV disease, and Influenza and pneumonia than females; while females experienced greater improvements in mortality from heart disease, diabetes, cancer, Acute bronchitis and bronchiolitis, and kidney disease.

Rates for the black population were at least 1.5 times greater compared with the white population for five of the leading causes of death ([table C](#)). The largest ratio was for homicide (5.7). Other causes for which the ratio was large include hypertension (2.8), kidney disease (2.3), Septicemia (2.3), and diabetes (2.1). For four of the leading causes, age-adjusted rates were lower for the black than the white population: the smallest black-to-white ratio was for suicide (0.4); that is, the risk of dying from suicide is more than double for the white population relative to the black population. Other such conditions were Alzheimer's disease and Chronic lower respiratory diseases, with a black-to-white ratio of 0.7 each, and Chronic liver disease and cirrhosis at 0.9.

The difference in life expectancy between black persons and white persons narrowed from 5.5 years in 2001 to 5.4 years in 2002. The narrowing in the black-white life expectancy gap was due primarily to greater improvements in mortality for the black population for unintentional injuries, heart disease, Chronic liver disease and cirrhosis, stroke, and Influenza and pneumonia.

Age-adjusted death rates were lower for the Hispanic population for 11 of the 15 leading causes of death relative to the non-Hispanic white population. The smallest ratios were for Chronic lower respiratory diseases and suicide (0.4 each). Other causes for which the ratio was considerably small include Alzheimer's disease and Pneumonitis due to solids and liquids (0.6 each). Rates for the Hispanic population were greater than for the non-Hispanic white population for three of the leading causes of death: homicide (2.6), Chronic liver disease and cirrhosis (1.7) and diabetes (1.6).

Leading causes of death for the total population and for specific subpopulations are examined in more detail in a separate report on leading causes by age, race, Hispanic origin, and sex (3).

Injury mortality by mechanism and intent

In 2002 a total of 161,269 deaths were classified as injury-related ([table 18](#)). Injury data are presented using the external cause of injury mortality matrix for ICD-10. The matrix was jointly conceived by the International Collaborative Effort (ICE) on Injury Statistics and the Injury Control and Emergency Health Services (ICEHS) section of the American Public Health Association (25,26). The two essential dimensions of the ICD codes for injuries form the basis for this framework: the mechanism of the injury and the manner or intent of the injury. The mechanism involves the circumstances of the injury (e.g., fall, motor vehicle accident, poisoning). The manner/intent of the injury involves whether the injury was inflicted purposefully or not (in some cases, intent cannot be determined) and, when intentional, whether the injury was self-inflicted (suicide) or inflicted upon another person (assault). In the list of 113 selected causes of death, the focus is on manner or intent with subcategories showing selected mechanisms. The matrix has two distinct advantages for the analysis of injury mortality data. First, it contains a comprehensive list of mechanisms. Second, data can be displayed by mechanism with subcategories of intent (as in [table 18](#)) or vice versa. Four major mechanisms of injury in 2002—motor-vehicle traffic, firearm, poisoning and falls—accounted for 73.1 percent of all injury deaths.

Motor vehicle traffic—In 2002 motor-vehicle traffic-related injuries resulted in 44,065 deaths, accounting for 27.3 percent of all injury deaths ([table 18](#)). The age-adjusted death rate for motor-vehicle traffic-related injuries increased by 2 percent from 2001 to 2002 from 14.9 per 100,000 U.S. standard population to 15.2.

Firearm—In 2002, 30,242 persons died from firearm injuries in the United States ([tables 18–20](#)), accounting for 18.8 percent of all injury deaths in 2002. Firearm suicide and homicide, the two major component causes, accounted for 56.6 and 39.1 percent, respectively, of all firearm injury deaths in 2002. In 2002 the age-adjusted death rate for firearm injuries was 10.4 deaths per 100,000 U.S. standard population. Males had an age-adjusted rate that was 6.6 times that for females, the black population had a rate that was 2.1 times that of the white population, and the non-Hispanic population had a rate that was 1.4 times that of the Hispanic population ([tables 19 and 20](#)). Between 2001 and 2002 the age-adjusted death rate for firearm injuries increased slightly from 10.3 to 10.4, although the increase was not statistically significant.

Poisoning—In 2002, 26,435 deaths occurred as the result of poisonings, 16.4 percent of all injury deaths ([table 18](#)). The majority of poisoning deaths were either unintentional (66.4 percent) or suicides (20.8 percent). However, a substantial proportion (12.6 percent) of poisonings were of undetermined intent. From 2001 to 2002 the age-adjusted death rate due to poisonings increased by 17.9 percent from 7.8 per 100,000 U.S. standard population to 9.2.

Falls—In 2002, 17,116 persons died as the result of falls, 10.6 percent of all injury deaths. The overwhelming majority (95.0 percent) of fall-related deaths were unintentional. From 2001 to 2002 the age-adjusted death rate for falls increased by 5.4 percent from 5.6 per 100,000 U.S. standard population to 5.9.

More detailed information on injury deaths, including data by age, race, Hispanic origin, sex and State are presented in a separate report (4). Also presented in this separate report are data describing type of injury and poisoning.

Drug-induced mortality

In 2002 a total of 26,018 persons died of drug-induced causes in the United States ([tables 21](#) and [22](#)). The category “drug-induced causes” includes not only deaths from dependent and nondependent use of drugs (legal and illegal use), but also poisoning from medically prescribed and other drugs. It excludes unintentional injuries, homicides, and other causes indirectly related to drug use. Also excluded are newborn deaths due to mother’s drug use. (For a list of drug-induced causes, see “[Technical Notes](#).”) In 2002 the age-adjusted death rate for drug-induced causes for males was 1.9 times the rate for females. The age-adjusted rate for the black population was 1.1 times the rate for the white population ([table 21](#)). The rate for the non-Hispanic white population was 1.6 times that of the Hispanic population and the rate for the non-Hispanic black population was 1.6 times that of the Hispanic population ([table 22](#)). Between 2001 and 2002 the age-adjusted death rate for drug-induced causes increased 18.4 percent from 7.6 deaths per 100,000 U.S. standard population to 9.0. For the major ethnic-race-sex groups, between 2001 and 2002, the age-adjusted death rate for drug-induced causes increased by 18.6 percent for white males, 26.4 percent for white females, 13.0 percent for black females, 16.3 percent for Hispanic males and 20 percent for Hispanic females. The rate did not change significantly for black males.

Alcohol-induced mortality

In 2002 a total of 19,928 persons died of alcohol-induced causes in the United States ([tables 23](#) and [24](#)). The category “alcohol-induced causes” includes not only deaths from dependent and nondependent use of alcohol but also accidental poisoning by alcohol. It excludes unintentional injuries, homicides, and other causes indirectly related to alcohol use as well as deaths due to fetal alcohol syndrome. (For a list of alcohol-induced causes, see “[Technical Notes](#).”) In 2002 the age-adjusted death rate for alcohol-induced causes for males was 3.4 times the rate for females, and the rate for the Hispanic population was 1.4 times the rate for the non-Hispanic white population ([tables 23](#) and [24](#)). Between 2001 and 2002 the age-adjusted death rate for alcohol-induced causes for the total population remained unchanged (6.9 per 100,000 U.S. standard population). For the major ethnic-race-sex groups, the rate decreased significantly only for black males, from 14.7 to 12.8.

Marital status

For those aged 15 years and over, the number of deaths in 2002 of persons who were married was 945,795; widowed, 925,609; never married, 247,823; and divorced, 273,973 ([table 25](#)) (see “[Technical Notes](#)”). Those never married had the highest age-adjusted death rate, followed by divorced, widowed, and married persons, respectively. The never-married group had an age-adjusted death rate 66.1 percent higher than the ever married and 2.2 times the rate for the currently married. Age-adjusted death rates for widowed and divorced persons were 81.5 percent and 83.3 percent higher, respectively, than for those who were currently married at the time of death.

For all age groups 15 years and over, death rates for married persons were much lower than those for never-married persons. For

ages 25–34 years, widowed persons had the highest death rates; but beginning at age 35, those who never married had the highest death rates.

For each marital status group, males had higher age-adjusted death rates than females, ranging from 34.1 percent greater for the never married to 74 percent greater for the currently married in 2002.

Educational attainment

Age-specific and age-adjusted death rates are shown by educational attainment for age groups in the range 25–64 years ([table 26](#)). In the 47 reporting States and the District of Columbia, a total of 234,768 decedents aged 25–64 years had completed 12 years of education, compared with 170,749 who had completed 13 years or more and 113,291 who had completed less than 12 years. For the total population, and for males and females separately, mortality is inversely associated with educational attainment; that is, the average risk of death decreases markedly with increasing educational attainment. The age-adjusted death rate for those with less than 12 years of education was 575.1 per 100,000 U.S. standard population—17.2 percent higher than the rate of 490.9 for those with 12 years of education and 2.7 times the rate for those with 13 years of education or more. Rates are shown only for ages 25–64 years because persons under age 25 may not have completed their education. Rates are not shown for the older ages because of misreporting of educational attainment on the death certificate (see “[Technical Notes](#)”). Data on educational attainment must be interpreted with caution because of misreporting on the death certificate and biases that result from differences between the classification of educational attainment on the death certificate and in census surveys (see “[Technical Notes](#)”).

Injury at work

For persons aged 15 years and over, a total of 5,307 deaths were reported on the death certificates due to injuries at work ([table 27](#)). Rates were lowest for age groups 15–24 years and 65 years and over. The risk of work-related death was much greater for males than for females; the age-adjusted death rate for males was 4.4 deaths per 100,000 U.S. standard population compared with 0.4 for females, resulting in a mortality ratio of 11:1. The age-adjusted rate for the white population (2.4) was slightly higher than the rate for the black population (2.1). The male-to-female ratios for the white and black populations were 11.3 and 10.3, respectively.

The number of deaths due to injury at work decreased by 2,996 from 2001 to 2002 to a level consistent with that in 2000. The increase in deaths between 2000 and 2001 was the result of the September 11, 2001, terrorist attacks. The age-adjusted death rate decreased by 38 percent ([table 28](#)) from 2001 to 2002. The decrease was substantial for females (60 percent) and for males (33.3 percent). The age-adjusted death rate for injury-at-work also decreased for both the white (36.8 percent) and for the black (32.3 percent) populations.

State of residence

Mortality patterns vary considerably by State ([table 29](#)). The State with the highest age-adjusted death rate in 2002 was Mississippi (1,036.3 per 100,000 standard population) with a rate 22.6 percent above the national average. The State with the lowest age-

adjusted death rate was Hawaii (660.6 per 100,000 standard population), with a rate almost 22 percent below the national average. The rate for the District of Columbia was 1,021.4 deaths per 100,000 standard population, 20.8 percent above the national average; however, the District of Columbia, as a city, is not comparable with the States. Variations in mortality by State are associated with differences in socioeconomic status, race, and ethnic composition as well as differences in risk for specific causes of death (27).

Infant mortality

In 2002 a total of 28,034 deaths occurred to children under 1 year ([table D](#)), 466 more deaths than in 2001. The infant mortality rate in 2002 increased to 7.0 infant deaths per 1,000 live births, compared with a rate of 6.8 in 2001. The infant mortality rate has either decreased or remained level each successive year through 2001 since 1958 (28) ([table 30](#) and [figure 6](#)). Because the infant mortality rate is one of the key indicators of the Nation's health, additional analysis was done to try to assess the factors accounting for the increase. Analysis of infant mortality and preliminary fetal death data for 2002 suggests that the perinatal mortality rate (the number of late fetal deaths (28 or more weeks of gestation) and early neonatal deaths (less than 7 days) per 1,000 live births plus late fetal deaths) remained unchanged (30). Final birth data for 2002 indicate that two key predictors of infant health, the percentage of births born preterm (less than 37 completed weeks of gestation) and low birthweight (less than 2,500 grams), also rose for 2002, continuing fairly long-term upward trends (29, 30). A more complete analysis of these and other factors will be addressed in the report of the 2002 linked birth and infant death file (31) and in a separate report that will be published as a supplement.

The rise in the infant mortality rate was concentrated in the neonatal period (less than 28 days), particularly the first week of life where more than half of all infant deaths typically occur. The neonatal mortality rate (deaths to infants aged 0–27 days per 1,000 live births) increased by 4.4 percent between 2001 and 2002 (from 4.5 to 4.7 per 1,000 live births). The postneonatal mortality rate (deaths to infants age 28 days–1 year per 1,000 live births) remained constant at 2.3 deaths per 1,000 live births.

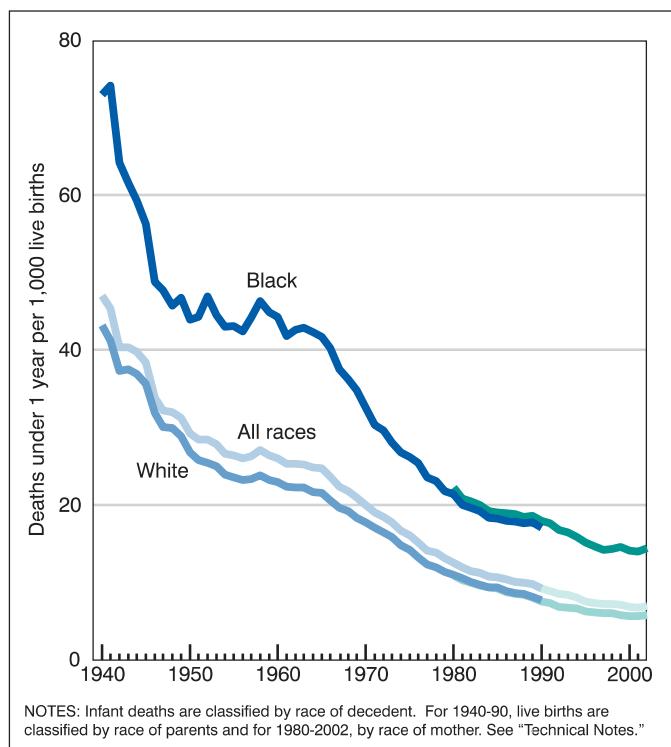

Figure 6. Infant mortality rates by race: United States, 1940–2002

Infant mortality data by race are shown in [tables 30](#) and [31](#). Caution should be exercised in analyzing infant mortality data by race due to problems with the reporting of race and Hispanic origin on the death certificate (17). The reader is directed to the report on the linked birth and infant death data file for a more accurate measure of race and infant mortality (31).

The 10 leading causes of infant death in 2002 accounted for 68.4 percent of all infant deaths in the United States ([table E](#)). In rank order, the 10 leading causes were: 1) Congenital malformations, deformations and chromosomal abnormalities (congenital malformations), 2) Disorders related to short gestation and low birth weight, not elsewhere

Table D. Number of infant, neonatal, and postneonatal deaths and mortality rates by sex: United States, 2001–2002

[Rates are infant (under 1 year), neonatal (under 28 days), and postneonatal (28 days–11 months) deaths per 1,000 live births in specified group]

Race and sex	2002		2001	
	Number	Rate	Number	Rate
Infant				
Total	28,034	7.0	27,568	6.8
Male	15,717	7.6	15,477	7.5
Female	12,317	6.3	12,091	6.1
Neonatal				
Total	18,747	4.7	18,265	4.5
Male	10,408	5.1	10,237	5.0
Female	8,339	4.2	8,028	4.1
Postneonatal				
Total	9,287	2.3	9,303	2.3
Male	5,309	2.5	5,240	2.5
Female	3,978	2.1	4,063	2.1

Table E. Number of infant deaths, percent of total infant deaths, and infant mortality rates for 2001, and percent change in infant mortality rates from 2001 to 2002 for the 10 leading causes of infant death in 2002: United States

[Rates are infant deaths per 100,000 live births; see "Technical Notes"]

Rank ¹	Cause of death (Based on the <i>Tenth Revision International Classification of Diseases, 1992</i>)	Number	Percent of total deaths	Rate	Percent change ² from 2001 to 2002
...	All causes	28,034	100.0	697.1	1.8
1	Congenital malformations, deformations and chromosomal abnormalities . . . (Q00–Q99)	5,623	20.1	139.8	2.1
2	Disorders related to short gestation and low birth weight, not elsewhere classified . . (P07)	4,637	16.5	115.3	5.3
3	Sudden infant death syndrome (R95)	2,295	8.2	57.1	2.9
4	Newborn affected by maternal complications of pregnancy ³ (P01)	1,708	6.1	42.5	14.2
5	Newborn affected by complications of placenta, cord and membranes (P02)	1,028	3.7	25.6	1.2
6	Accidents (unintentional injuries) (V01–X59)	946	3.4	23.5	-2.9
7	Respiratory distress of newborn (P22)	943	3.4	23.4	-6.8
8	Bacterial sepsis of newborn (P36)	749	2.7	18.6	7.5
9	Diseases of the circulatory system (I00–I99)	667	2.4	16.6	7.8
10	Intrauterine hypoxia and birth asphyxia (P20–P21)	583	2.1	14.5	9.0
...	All other causes (Residual)	8,855	31.6	220.2	...

... Category not applicable.

¹Rank based on number of deaths; see "Technical Notes."²Percent change based on a comparison of the 2002 infant mortality rate with the 2001 infant mortality rate.³Cause-of-death coding changes may affect comparability with the previous year's data for this cause; see "Technical Notes."

classified (low birth weight), 3) Sudden infant death syndrome (SIDS), 4) Newborn affected by maternal complications of pregnancy (maternal complications), 5) Newborn affected by complications of placenta, cord and membranes (cord and placental complications), 6) Accidents (unintentional injuries), 7) Respiratory distress of newborn, 8) Bacterial sepsis of newborn, 9) Diseases of the circulatory system (circulatory diseases), and 10) Intrauterine hypoxia and birth asphyxia. Respiratory distress of newborn dropped from the sixth leading cause to the seventh, while unintentional injuries increased from the seventh to the sixth.

The introduction of ICD-10 for 1999 data affected trends in many of the leading causes of infant death. For a description of changes affecting infant causes of death, the reader is directed to review the 1999 final report on mortality (22) and the preliminary report on comparability of cause of death between ICD-9 and ICD-10 (21).

Changes in infant mortality rates by cause of death among the ten leading causes were statistically significant for two conditions: the rate for low birth weight increased by 5.3 percent and the rate for maternal complications increased by 14.2 percent. Part of the large increase in the infant mortality rate for maternal complications is due to a change in coding rules for this cause; see "Technical Notes."

Maternal mortality

In 2002 a total of 357 women were reported to have died of maternal causes (tables 33 and 34), a decrease of 42 deaths from the 2001 total. As in previous years, the number of maternal deaths does not include all deaths occurring to pregnant women, but only those deaths reported on the death certificate that were assigned to causes related to or aggravated by pregnancy or pregnancy management (ICD-10 codes A34, O00–O95, and O98–O99). Further, the number excludes deaths occurring more than 42 days after the termination of pregnancy and deaths of pregnant women due to external causes (unintentional injuries, homicides, and suicides) (7).

The maternal mortality rate for 2002 was 8.9 deaths per 100,000 live births. Black women have a substantially higher risk of maternal

death than white women. The maternal mortality rate for black women was 24.9, 4.2 times the rate for white women (6.0 deaths per 100,000 live births).

Hispanic maternal mortality—The maternal mortality rate for Hispanic women was 7.1 deaths per 100,000 live births. As with other statistics involving Hispanic origin, these should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys (see "Technical Notes").

List of Detailed Tables

1.	Number of deaths, death rates, and age-adjusted death rates, by race and sex: United States, 1940, 1950, 1960, 1970, and 1980-2002	17
2.	Number of deaths, death rates, and age-adjusted death rates, by Hispanic origin, race for non-Hispanic population, and sex: United States, 1997-2002	20
3.	Number of deaths and death rates, by age, race, and sex: United States, 2002	21
4.	Number of deaths and death rates by Hispanic origin, race for non-Hispanic population, age, and sex: United States, 2002	22
5.	Number of deaths and death rates by age, and age-adjusted death rates, according to specified Hispanic origin, race for non-Hispanic population, and sex: United States, 2002	23
6.	Abridged life table for the total population, 2002	25
7.	Life expectancy at selected ages by race and sex: United States, 2002	25
8.	Life expectancy at birth by race and sex: United States, 1940, 1950, 1960, 1970, and 1975-2002	26
9.	Death rates by age and age-adjusted death rates for the 15 leading causes of death in 2002: United States, 1999-2002	27
10.	Number of deaths from 113 selected causes by age: United States, 2002	29
11.	Death rates for 113 selected causes by age: United States, 2002	33
12.	Number of deaths from 113 selected causes by race and sex: United States, 2002	38
13.	Number of deaths from 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002	43
14.	Death rates for 113 selected causes by race and sex: United States, 2002	51
15.	Death rates for 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002	56
16.	Age-adjusted death rates for 113 selected causes by race and sex: United States, 2002	64
17.	Age-adjusted death rates for 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002	69
18.	Number of deaths, death rates, and age-adjusted death rates for injury deaths according to mechanism and intent of death: United States, 2002	77
19.	Number of deaths, death rates, and age-adjusted death rates for injury by firearms, by race and sex: United States, 1999-2002	79
20.	Number of deaths, death rates, and age-adjusted death rates by injury by firearms, by Hispanic origin, race for non-Hispanic population, and sex: United States, 1999-2002	80
21.	Number of deaths, death rates, and age-adjusted death rates for drug-induced causes, by race and sex: United States, 1999-2002	81
22.	Number of deaths, death rates, and age-adjusted death rates for drug-induced causes, by Hispanic origin, race for non-Hispanic population, and sex: United States, 1999-2002	82
23.	Number of deaths, death rates, and age-adjusted death rates for alcohol-induced causes, by race and sex: United States, 1999-2002	83
24.	Number of deaths, death rates, and age-adjusted death rates for alcohol-induced causes, by Hispanic origin, race for non-Hispanic population, and sex: United States, 1999-2002	84
25.	Number of deaths, death rates, and age-adjusted death rates for ages 15 years and over, by marital status and sex: United States, 2002	85
26.	Number of deaths, death rates, and age-adjusted death rates for ages 25-64 years, by educational attainment and sex: Total 47 reporting States and the District of Columbia, 2002	86
27.	Number of deaths, death rates, and age-adjusted death rates for ages 15 years and over, by injury at work, race, and sex: United States, 2002	87
28.	Number of deaths, death rates, and age-adjusted death rates for injury at work, by race and sex: United States, 1993-2002	88
29.	Number of deaths, death rates, and age-adjusted death rates for major causes of death for the United States, and each State, Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas, 2002	89
30.	Infant, neonatal, and postneonatal mortality rates by race and sex: United States, 1940, 1950, 1960, 1970, and 1975-2002	94
31.	Number of infant deaths and infant mortality rates for 130 selected causes by race: United States, 2002	96
32.	Number of infant and neonatal deaths and mortality rates, by race for the United States, each State, Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas, and by sex for the United States, 2002	99
33.	Number of maternal deaths and maternal mortality rates for selected causes by race: United States, 2002	100
34.	Number of maternal deaths and maternal mortality rates for selected causes, by Hispanic origin and race for non-Hispanic population: United States, 2002	101

Table 1. Number of deaths, death rates, and age-adjusted death rates, by race and sex: United States, 1940, 1950, 1960, 1970, and 1980–2002

[Crude rates on an annual basis per 100,000 population in specified age group; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Rates are based on populations enumerated as of April 1 for census years and estimated as of July 1 for all other years; see "Technical Notes." Beginning 1970, excludes deaths of nonresidents of the United States. Data for specified races other than white and black should be interpreted with caution because of inconsistencies between reporting race on death certificates and on censuses and surveys; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

See footnotes at end of table.

Table 1. Number of deaths, death rates, and age-adjusted death rates, by race and sex: United States, 1940, 1950, 1960, 1970, and 1980–2002—Con.

[Crude rates on an annual basis per 100,000 population in specified age group; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Rates are based on populations enumerated as of April 1 for census years and estimated as of July 1 for all other years; see "Technical Notes." Beginning 1970, excludes deaths of nonresidents of the United States. Data for specified races other than white and black should be interpreted with caution because of inconsistencies between reporting race on death certificates and on censuses and surveys; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

--- Data not available.

¹For 1940–91 includes deaths among races not shown separately; beginning in 1992 records coded as other races and records for which race was unknown, not stated, or not classifiable were assigned to the race of previous record; see "Technical Notes."²Includes Aleuts and Eskimos.³Includes Chinese, Filipino, Hawaiian, Japanese, and Other Asian or Pacific Islander.⁴For method of computation, see "Technical Notes."

Table 2. Number of deaths, death rates, and age-adjusted death rates, by Hispanic origin, race for non-Hispanic population, and sex: United States, 1997–2002

[Crude rates on an annual basis per 100,000 population in specified group; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Rates are based on populations enumerated as of April 1 for 2000 and are estimated as of July 1 for all other years; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

¹Includes Aleuts and Eskimos.²Includes Chinese, Filipino, Hawaiian, Japanese, and Other Asian or Pacific Islander.³Figures for age not stated are included in "All ages" but not distributed among age groups.⁴Death rates for "Under 1 year" (based on population estimates) differ from infant mortality rates (based on live births); see "Technical Notes."

Table 4. Number of deaths and death rates by Hispanic origin, race for non-Hispanic population, age, and sex: United States, 2002

[Rates per 100,000 population in specified group; see "Technical Notes." Populations used for computing death rates are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

¹Figures for origin not stated are included in "All origins" but not distributed among specified origins.

²Includes races other than white and black.

³Figures for age not stated are included in "All ages" but not distributed among age groups.

⁴Death rates for "Under 1 year" (based on population estimates) differ from infant mortality rates (based on live births); see "Technical Notes."

Table 5. Number of deaths and death rates by age, and age-adjusted death rates, by specified Hispanic origin, race for non-Hispanic population, and sex: United States, 2002

[Rates per 100,000 population in specified group; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates for all origins, Hispanic, non-Hispanic, non-Hispanic white, and non-Hispanic black are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; populations used for computing death rates for Mexican, Puerto Rican, Cuban, Central and South American, and other and unknown Hispanic are based on the Current Population Survey adjusted to resident population control totals. The control totals are 2000-based population estimates for the United States for July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Table 5. Number of deaths and death rates by age, and age-adjusted death rates, by specified Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Rates per 100,000 population in specified group; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates for all origins, Hispanic, non-Hispanic, non-Hispanic white, and non-Hispanic black are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; populations used for computing death rates for Mexican, Puerto Rican, Cuban, Central and South American, and other and unknown Hispanic are based on the Current Population Survey adjusted to resident population control totals. The control totals are 2000-based population estimates for the United States for July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

... Category not applicable.

* Figure does not meet standards of reliability or precision; see "Technical Notes."

– Quantity zero.

¹Death rates for "Under 1 year" (based on population estimates) differ from infant mortality rates (based on live births); see "Technical Notes."

²For method of computation, see "Technical Notes."

³Includes races other than white and black.

⁴Includes deaths for which Hispanic origin was not reported on the death certificate.

⁵Figures for age not stated are included in "All ages" but not distributed among age groups.

⁶Figures for origin not stated are included in "All origins" but not distributed among specified origins.

⁷Includes Central and South American and Other and unknown Hispanic.

¹Cause-of-death coding changes may affect comparability with the previous year's data for this cause; see "Technical Notes."

NOTE: Complete confirmation of deaths from selected causes of death, considered to be of public health concern, were not provided by the following States—Alabama, California, Illinois, Minnesota, Mississippi, Nebraska, New York, Pennsylvania, Texas, and West Virginia; see "Technical Notes."

Table 13. Number of deaths from 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002

[Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

See footnotes at end of table.

Table 13. Number of deaths from 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Cause of death (Based on the <i>International Classification of Diseases, Tenth Revision</i> , 1992)	All origins			Hispanic			Non-Hispanic ¹		
	Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

Table 13. Number of deaths from 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines.]

Cause of death (Based on the <i>International Classification of Diseases, Tenth Revision</i> , 1992)	Non-Hispanic white			Non-Hispanic black			Origin not stated ²

See footnotes at end of table.

Table 13. Number of deaths from 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Cause of death (Based on the <i>International Classification of Diseases, Tenth Revision</i> , 1992)	Non-Hispanic white			Non-Hispanic black			Origin not stated ²		
	Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

Table 15. Death rates for 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Rates per 100,000 population in specified group. Populations used for computing death rates are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding the cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Table 15. Death rates for 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Rates per 100,000 population in specified group. Populations used for computing death rates are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding the cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Cause of death (Based on the <i>International Classification of Diseases, Tenth Revision</i> , 1992)	Non-Hispanic white			Non-Hispanic black		
	Both sexes	Male	Female	Both sexes	Male	Female
Other and unspecified malignant neoplasms of lymphoid, hematopoietic and related tissue (C96)	0.0	0.0	0.0	*	*	*
All other and unspecified malignant neoplasms (C17,C23–C24,C26–C31, C37–C41,C44–C49,C51–C52,C57–C60, C62–C63,C66,C68–C69,C73–C80,C97)	26.0	27.2	24.9	18.7	19.4	18.0

Table 16. Age-adjusted death rates for 113 selected causes by race and sex: United States, 2002—Con.

[Age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes." The asterisks (*) preceding cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Cause of death (Based on the <i>International Classification of Diseases, Tenth Revision</i> , 1992)							All other					
	All races			White			Total			Black		
	Both sexes	Male	Female									
Malignant neoplasm of ovary (C56)	5.1	...	9.0	5.3	...	9.4	4.0	...	6.8	4.4	...	7.4

. . . Category not applicable.

¹Cause-of-death coding changes may affect comparability with the previous year's data for this cause; see "Technical Notes."

NOTE: Complete confirmation of deaths from selected causes of death, considered to be of public health concern, were not provided by the following States—Alabama, California, Illinois, Minnesota, Mississippi, Nebraska, New York, Pennsylvania, Texas, and West Virginia; see "Technical Notes."

Table 17. Age-adjusted death rates for 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002

[Age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding the cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Table 17. Age-adjusted death rates for 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding the cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Cause of death (Based on the <i>International Classification of Diseases, Tenth Revision</i> , 1992)	All origins ¹			Hispanic			Non-Hispanic ²

Table 17. Age-adjusted death rates for 113 selected causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 2002—Con.

[Age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." The asterisks (*) preceding the cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Table 22. Number of deaths, death rates, and age-adjusted death rates, for drug-induced causes by Hispanic origin, race for non-Hispanic population, and sex: United States, 1999–2002

[Rates on an annual basis per 100,000 population in specified group; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Rates are based on populations enumerated as of April 1 for 2000 and estimated as of July 1 for all other years; see "Technical Notes." Race and Hispanic origin are reported separately on the death certificate. Persons of Hispanic origin may be of any race. Data for Hispanic persons are not tabulated separately by race; data for non-Hispanic persons are tabulated by race. Data for Hispanic origin should be interpreted with caution because of inconsistencies between reporting Hispanic origin on death certificates and on censuses and surveys; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines. For the listing of drug-induced causes, see "Technical Notes"]

* Figure does not meet standards of reliability or precision; see "Technical Notes."

¹Excludes figures for age not stated.

²Calculated based on ages 25 years and over. For method of computation, see "Technical Notes."

³Figures for marital status not stated are included in totals for Both sexes, Male, and Female but are not distributed among specified marital status groups.

Table 26. Number of deaths, death rates, and age-adjusted death rates for ages 25–64 years, by educational attainment and sex: Total of 47 reporting States and the District of Columbia, 2002

[Rates per 100,000 in specified group; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Population estimates used for computing death rates are based on the Current Population Survey adjusted to July 1, 2002, resident population control totals for 47 reporting States and the District of Columbia. For rates, the definition of educational attainment differs for the numerator and denominator; see "Technical Notes"]

Table 29. Number of deaths, death rates, and age-adjusted death rates for major causes of death for the United States, and each State, Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas, 2002—Con.

[Rates per 100,000 population; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates are postcensal estimates based on the 2000 census estimated as of July 1, 2002; see "Technical Notes." Numbers after causes of death are categories of the *International Classification of Diseases, Tenth Revision*, 1992. The asterisks (*) preceding the cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes"]

Table 29. Number of deaths, death rates, and age-adjusted death rates for major causes of death for the United States, and each State, Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas, 2002—Con.

[Rates per 100,000 population; age-adjusted rates per 100,000 U.S. standard population; see "Technical Notes." Populations used for computing death rates are postcensal estimates based on the 2000 census estimated as of July 1, 2002; see "Technical Notes." Numbers after causes of death are categories of the *International Classification of Diseases, Tenth Revision*, 1992. The asterisks (*) preceding the cause-of-death codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10); see "Technical Notes"]

Area	Motor vehicle accidents ⁴			Intentional self-harm (suicide)(*U03,X60–X84,Y87.0)			Assault (homicide) (*U01–*U02,X85–Y09,Y87.1)			Injury by firearms ⁵		
	Number	Rate	Age-adjusted rate ¹	Number	Rate	Age-adjusted rate ¹	Number	Rate	Age-adjusted rate ¹	Number	Rate	Age-adjusted rate ¹
Puerto Rico ³	533	13.8	13.6	240	6.2	6.5	733	19.0	18.5	698	18.1	17.6
Virgin Islands ³	12	*	*	2	*	*	41	37.7	39.8	36	33.1	35.2

American Samoa ³	3	*	*	1	*	*	10	*	*	1	*	*
Northern Marianas ³	4	*	*	4	*	*	4	*	*	2	*	*

* Figure does not meet standards of reliability or precision; see "Technical Notes."

— Quantity zero.

¹Death rates are affected by the population composition of the area. Age-adjusted death rates should be used for comparisons between areas; for method of computation, see "Technical Notes."

²Excludes data for Puerto Rico, Virgin Islands, Guam, American Samoa and Northern Marianas.

³Age-adjusted death rates for Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas are calculated using different age groups in the weighting procedure; see "Technical Notes."

⁴ICD-10 codes for Motor vehicle accidents are V02–V04,V09.0,V09.2,V12–V14,V19.0–V19.2,V19.4–V19.6,V20–V79,V80.3–V80.5,V81.0–V81.1,V82.0–V82.1,V83–V86,V87.0–V87.8,V88.0–V88.8,V89.0,V89.2.

⁵ICD-10 codes for Injury by firearms are *U01.4,W32–W34,X72–X74,X93–X95,Y22–Y24,Y35.0.

Table 30. Infant, neonatal, and postneonatal mortality rates by race and sex: United States, 1940, 1950, 1960, 1970, and 1975–2002

[Rates are infant (under 1 year), neonatal (under 28 days), and postneonatal (28 days–11 months) deaths per 1,000 live births in specified group. Beginning in 1980, race for live births is tabulated according to race of mother; see "Technical Notes." Race categories are consistent with the 1977 Office of Management and Budget guidelines]

Technical Notes

Nature and sources of data

Data in this report are based on information from all death certificates filed in the 50 States and the District of Columbia and are processed by the Centers for Disease Control and Prevention's National Center for Health Statistics (NCHS). Data for 2002 are based on records of deaths that occurred during 2002 and were received as of November 18, 2003. The U.S. Standard Certificate of Death—which is used as a model by the States—was last revised in 1989; for additional details see the 1989 revision of the U.S. standard certificates and reports (32) and Technical Appendix of Vital Statistics of the United States, 1989, Volume II, Mortality, part A (33). Data for Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Northern Marianas are included in tables showing data by State, but are not included in U.S. totals.

Mortality statistics are based on information coded by the States and provided to the National Center for Health Statistics (NCHS) through the Vital Statistics Cooperative Program (VSCP) and from copies of the original certificates received by NCHS from the State registration offices. In 2002 all the States and the District of Columbia participated in this program and submitted part or all of the mortality data for 2002 in electronic data files to NCHS. All States provided pre-coded medical (cause-of-death) data to NCHS except Illinois, Kentucky, Ohio, and West Virginia, and the District of Columbia. For 2002 all States submitted pre-coded demographic data for all deaths.

Data for the entire United States refer to events occurring within the United States. Data shown for geographic areas are by place of residence. Beginning with 1970, mortality statistics for the United States exclude deaths of nonresidents of the United States. All data exclude fetal deaths.

Mortality statistics for Puerto Rico, Virgin Islands, American Samoa, and Northern Marianas exclude deaths of nonresidents of Puerto Rico, Virgin Islands, American Samoa, and Northern Marianas, respectively. For Guam, however, mortality statistics exclude deaths that occurred to a resident of any place other than Guam or the United States.

Cause-of-death classification

The mortality statistics presented in this report were compiled in accordance with World Health Organization (WHO) regulations, which specify that member nations classify and code causes of death in accordance with the current revision of the *International Classification of Diseases* (ICD). The ICD provides the basic guidance used in virtually all countries to code and classify causes of death. Effective with deaths occurring in 1999, the United States began using the Tenth Revision of this classification (ICD-10) (7). For earlier years causes of death were classified according to the revisions then in use—1979–98, Ninth Revision; 1968–78, Eighth Revision, adapted for use in the United States; 1958–67, Seventh Revision; and 1949–57, Sixth Revision.

Changes in classification of causes of death due to these revisions may result in discontinuities in cause-of-death trends. Consequently, cause-of-death comparisons among revisions require consideration of comparability ratios and, where available, estimates of their standard errors. Comparability ratios between the Ninth and Tenth Revisions,

between the Eighth and Ninth Revisions, between the Seventh and Eighth Revisions, and between the Sixth and Seventh Revisions may be found in other NCHS reports (21,34–36).

The ICD not only details disease classification but also provides definitions, tabulation lists, the format of the death certificate, and the rules for coding cause of death. Cause-of-death data presented in this publication were coded by procedures outlined in annual issues of the NCHS *Instruction Manual* (37,38). It includes rules for selecting the underlying cause of death for tabulation purposes, definitions, tabulation lists, and regulations on the use of the ICD.

Before data for 1968, mortality medical data were based on manual coding of an underlying cause of death for each certificate in accordance with WHO rules. Effective with data year 1968, NCHS converted to computerized coding of the underlying cause and manual coding of all causes (multiple causes) on the death certificate. In this system, called "Automated Classification of Medical Entities" (ACME) (39), multiple cause codes serve as inputs to the computer software that employs WHO rules to select the underlying cause. All cause-of-death data in this report are coded using ACME.

The ACME system is used to select the underlying cause of death for all death certificates in the United States. In addition, NCHS has developed two computer systems as inputs to ACME. Beginning with 1990 data, the Mortality Medical Indexing, Classification, and Retrieval system (MICAR) (40,41), was introduced to automate coding multiple causes of death. In addition, MICAR provides more detailed information on the conditions reported on death certificates than is available through the ICD code structure. Then, beginning with data year 1993, SuperMICAR, an enhancement of the MICAR system, was introduced. SuperMICAR allows for literal entry of the multiple cause-of-death text as reported by the certifier. This information is then automatically processed by the MICAR and ACME computer systems. Records that cannot be automatically processed by MICAR or SuperMICAR are manually multiple-cause coded and then further processed through ACME.

For 2002 approximately 77 percent of the Nation's death records were multiple-cause coded using SuperMICAR and 23 percent, using MICAR only. This represents data from 41 States, New York City and the District of Columbia that were coded by SuperMICAR and data from 9 States that were coded by MICAR.

In this report tabulations of cause-of-death statistics are based solely on the underlying cause of death. The underlying cause is defined by WHO as "the disease or injury which initiated the train of events leading directly to death, or the circumstances of the accident or violence which produced the fatal injury" (7). It is selected from the conditions entered by the physician in the cause-of-death section of the death certificate. When more than one cause or condition is entered by the physician, the underlying cause is determined by the sequence of conditions on the certificate, provisions of the ICD, and associated selection rules and modifications. Generally, more medical information is reported on death certificates than is directly reflected in the underlying cause of death. This is captured in NCHS multiple cause-of-death statistics (42–44).

Tabulation lists and cause-of-death ranking

Tabulation lists for ICD-10 are published in the NCHS *Instruction Manual*, Part 9, ICD-10 Cause-of-Death Lists for Tabulating Mortality Statistics (updated October 2002) (45). For this report, two

tabulation lists are used, namely, the List of 113 Selected Causes of Death used for deaths of all ages, and the List of 130 Selected Causes of Infant Death used for infants. These lists are also used to rank leading causes of death for the two population groups. For the List of 113 Selected Causes of Death, the group titles Major cardiovascular diseases (ICD-10 codes I00–I78) and Symptoms, signs and abnormal clinical and laboratory findings, not elsewhere classified (ICD-10 codes R00–R99) are not ranked. In addition, category titles that begin with the words "Other" and "All other" are not ranked to determine the leading causes of death. When one of the titles that represents a subtotal is ranked (for example, Tuberculosis (ICD-10 codes A16–A19)), its component parts are not ranked (in this case, Respiratory tuberculosis (ICD-10 code A16) and Other tuberculosis (ICD-10 codes A17–A19)). For the List of 130 Selected Causes of Infant Death, the same ranking procedures are used, except that the category Major cardiovascular diseases is not in the list. More detail regarding ranking procedures can be found in "Deaths: Leading Causes for 2002" (3).

Leading cause-of-death trends, discussed in this report, are based on cause-of-death data according to ICD-10 for 1999–2002, and on data for the most comparable ICD-9 cause-of-death titles for 1979–98. Tables showing ICD-9 categories that are comparable to the ICD-10 titles in the list of 113 selected causes of death may be found in "Comparability of Cause of Death Between ICD-9 and ICD-10: Preliminary Estimates" (21) and "Deaths: Final Data for 1999" (22). Although in some cases categories from the list of 113 selected causes are identical to those in the old list of 72 selected causes of death used with ICD-9, it is important to note that many of these categories are not comparable with categories in the list of 72 selected causes even though the cause-of-death titles may be the same.

Trend data for 1978–98 that are classified by ICD-9 but are sorted into the list of 113 selected causes of death developed for ICD-10 can be found on the mortality Web site at <http://www.cdc.gov/nchs/data/statab/hist001r.pdf>.

Revision of the ICD and resulting changes in classification and rules for selecting the underlying cause of death have important implications for the analysis of mortality trends by cause of death. For some causes of death the discontinuity in trend can be substantial (21). Therefore, considerable caution should be used in analyzing cause-of-death trends for periods of time that extend across more than one revision of the ICD.

Codes for terrorism

Beginning with data for 2001, NCHS introduced categories *U01–*U03 for classifying and coding deaths due to acts of terrorism. The asterisks before the category codes indicate that they are not part of the *International Classification of Diseases, Tenth Revision* (ICD-10). Deaths classified to the terrorism categories are included in the categories for Assault (homicide) and Intentional self-harm (suicide) in the 113 cause-of-death list and in the category for Assault (homicide) in the 130 cause-of-death list for infants. Additional information on these new categories can be found at http://www.cdc.gov/nchs/about/otheract/icd9/terrorism_code.htm.

Race and Hispanic origin

Race and Hispanic origin are reported separately on the death certificate. Therefore, data shown by race include persons of

Hispanic and non-Hispanic origin, and data for Hispanic origin include persons of any race. In this report, unless otherwise specified, deaths of Hispanic origin are included in the totals for each race group—white, black, American Indian, and Asian or Pacific Islander (API)—according to the decedent's race as reported on the death certificate. Data shown for Hispanic persons include all persons of Hispanic origin of any race.

Mortality data for the Hispanic-origin population are based on deaths to residents of all 50 States and the District of Columbia. Data year 1997 was the first year that mortality data for the Hispanic population were available for the entire United States.

Quality of race and Hispanic origin data—Death rates for Hispanic, American Indian, and API persons should be interpreted with caution because of inconsistencies in reporting Hispanic origin or race on the death certificate as compared with race on censuses, surveys, and birth certificates. Studies have shown under-reporting on death certificates of American Indians, API, and Hispanic decedents; and undercounts of these groups in the censuses (17,46).

A number of studies have been conducted on the reliability of race reported on the death certificate by comparing race on the death certificate with that reported on another data collection instrument, such as the census or a survey. Differences may arise because of differences in who provides race information on the compared records. Race information on the death certificate is reported by the funeral director as provided by an informant or in the absence of an informant, on the basis of observation. In contrast, race on the census or on the Current Population Survey (CPS) is obtained while the individual is alive and is self-reported or reported by another member of the household familiar with the individual and, therefore, may be considered more valid. A high level of agreement between the death certificate and the census or survey report is essential to assure unbiased death rates by race.

Studies (46,47) show that a person self-reported as American Indian or Asian on census or survey records was sometimes reported as white on the death certificate. The net effect of misclassification is an underestimation of deaths and death rates for races other than white and black. In addition, undercoverage of minority groups in the census and resultant population estimates, introduces biases into death rates by race (6,17,48). Estimates of the approximate effect of the combined bias due to race misclassification on death certificates and under-enumeration on the 1990 census are as follows: white, -1.0 percent; black, -5.0; American Indian, +20.6; Asian or Pacific Islander, +10.7 (17). Comparable information is not yet available on the 2000 census.

The National Longitudinal Mortality Study (NLMS) examined the reliability of Hispanic origin reported on 43,520 death certificates with that reported on a total of 12 Current Population Surveys conducted by the U.S. Bureau of the Census for the years 1979–85 (17). In this study, agreement—on a record-by-record basis—was 89.7 percent for any report of Hispanic origin. The ratio of deaths for CPS divided by deaths for death certificate was 1.07 indicating net underreporting of Hispanic origin on death certificates by 7 percent as compared with self-reports on the surveys. Death rates for the Hispanic-origin population are also affected by under-coverage of this population group in the census and resultant population estimates; the estimated net correction, taking into account both sources of bias, is 1.6 percent (17,48).

Other races and race not stated—Beginning in 1992 all records coded as "Other races" (0.04 percent of the total deaths in 2002) were

assigned to the specified race of the previous record. Records for which race was unknown, not stated, or not classifiable (0.08 percent) were assigned the race designation of the previous record.

Infant and maternal mortality rates—For 1989–2002, as in previous years, infant and maternal deaths continue to be tabulated by the race of the decedent. However, beginning with the 1989 data year, the method of tabulating live births by race was changed from race of parents to race of mother as stated on the birth certificate. This change affects infant and maternal mortality rates because live births are the denominators of these rates (33,49). To improve continuity and ease of interpretation, trend data by race in this report have been rebtabulated by race of mother for all years beginning with the 1980 data year.

Quantitatively, the change in the basis for tabulating live births by race results in more white births and fewer black births and births of other races. Consequently, infant and maternal mortality rates under the new tabulating procedure tend to be about 2 percent lower for white infants and about 5 percent higher for black infants than when they are computed by the previous method of tabulating live births by race of parents. Rates for most other minority races also are higher when computed by race of mother (49,50).

Infant mortality rates for the Hispanic-origin population are based on numbers of resident infant deaths reported to be of Hispanic origin and numbers of resident live births by Hispanic origin of mother for the United States. In computing infant mortality rates, deaths and live births of unknown origin are not distributed among the specified Hispanic and non-Hispanic groups. In 2002 the percent of infant deaths of unknown origin was 0.3 and the percent of live births to mothers of unknown origin was 0.6 for the United States.

Small numbers of infant deaths for specific Hispanic-origin groups result in infant mortality rates subject to relatively large random variation (see “Random variation”). Infant mortality rates by Hispanic origin are less subject to reporting error when based on linked files of infant deaths and live births (30).

Infant mortality rates calculated from the general mortality file for specified race and/or Hispanic origin are in error because of reporting problems that affect the classification of race and Hispanic origin on the birth and death certificates for the same infant. Infant mortality rates by specified race and Hispanic origin are more accurate when based on the linked file of infant deaths and live births (30). The linked file computes infant mortality rates using the race and/or Hispanic origin of the mother from the birth certificate in both the numerator and denominator of the rate. In addition, mother's race and/or Hispanic origin from the birth certificate is considered to be more accurately reported than infant's race and/or Hispanic origin from the death certificate because, on the birth certificate, race is generally reported by the mother at the time of delivery whereas, on the death certificate, infant's race and/or Hispanic origin is reported by an informant, usually the mother but sometimes by the funeral director. Estimates of reporting errors have been made by comparing rates based on the linked files with those in which the race of infant death is based on information from the death certificate (17,30).

Life tables

The life table provides a comprehensive measure of the effect of mortality on life expectancy. It is composed of sets of values showing the mortality experience of a hypothetical group of infants born at the same time and subject throughout their lifetime to the age-specific

death rates of a particular time period, usually a given year. Beginning with final data reported for 1997, the life table methodology was changed from previous annual reports. Previously, U.S. life tables were abridged and constructed by reference to a standard table (51). In addition, the age range for these life tables was limited to 5-year age groups ending with the age group 85 years and over.

Beginning with 1997 mortality data, a revised life table methodology was used to construct complete life tables by single years of age that extend to age 100 (52) using a methodology similar to that of the decennial life tables (53). The advantages of the new over the previous methodology are its comparability with decennial life table methodology, greater accuracy, and greater age detail. A comparison of the two methods shows small differences in resulting values for life expectancy (52). Although the new method produces complete life tables, that is, life tables by single years of age, life table data shown in this report are summarized in 5-year age groupings. To calculate the probability of dying at each age, the revised methodology uses vital statistics death rates for ages under 85 years and mortality data from the Medicare program for ages over 85 years. Medicare data were used to model the probability of dying at ages 85 and over because the data are shown to be significantly more reliable than vital statistics data at the oldest ages (54).

The life tables presented in this report use a slight modification of the new life table method introduced in 1997 as a result of a change in the age detail of populations received from the U.S. Census Bureau. Populations for 2000, 2001 and 2002 were provided by single year of age up to age 84, followed by “85 years and over,” and as a result it was not possible to apply the same smoothing technique that has been used when population figures in single years of age up to ages “100 years and over” were available. Accordingly, Medicare data were used to estimate the probability of dying by single year of age for ages up to “100 years and over.”

Revised life expectancies were not computed for 1991–99 because revised intercensal populations, consistent with the 2000 census, were not available by single years of age for the 1990s as of the writing of this report.

Causes of death contributing to changes in life expectancy

Causes of death contributing to changes in life expectancy were estimated using a life table partitioning technique. The method partitions changes into component additive parts. This method identifies the causes of death having the greatest influence, positive or negative, on changes in life expectancy (18,55).

Injury mortality by mechanism and intent

Injury mortality data are presented using an alternative framework in [table 18](#). In this framework, causes of injury deaths are organized principally by mechanism (e.g. firearm or poisoning), and secondarily by manner, or intent of death (e.g. unintentional, suicide, homicide, etc.).

In addition, the number of deaths for selected causes in this framework may differ from those shown in tables that use the standard mortality tabulation lists. Following WHO conventions, standard mortality tabulations ([table 10](#)) present external causes of death (ICD-10 codes *U01–*U03,V01–Y89). In contrast, the alternative

framework ([table 18](#)) excludes deaths classified to Complications of medical and surgical care (ICD-10 codes Y40–Y84, Y88). For additional information on injury data presented in this framework, see <http://www.cdc.gov/nchs/about/otheract/ice/matrix10.htm> and “Deaths: Injuries, 2002” (4).

Codes for firearm deaths

Causes of death attributable to firearm mortality include ICD-10 codes *U01.4, Terrorism involving firearms (homicide); W32–W34, Accidental discharge of firearms; X72–X74, Intentional self-harm (suicide) by discharge of firearms; X93–X95, Assault (homicide) by discharge of firearms; Y22–Y24, Discharge of firearms, undetermined intent; and Y35.0, Legal intervention involving firearm discharge. Deaths from injury by firearms exclude deaths due to explosives and other causes indirectly related to firearms.

Codes for drug-induced deaths

Causes of death attributable to drug-induced mortality include selected codes from the ICD-10 title Mental and behavioral disorders due to psychoactive substance use, specifically, ICD-10 codes F11.0–F11.5, F11.7–F11.9, F12.0–F12.5, F12.7–F12.9, F13.0–F13.5, F13.7–F13.9, F14.0–F14.5, F14.7–F14.9, F15.0–F15.5, F15.7–F15.9, F16.0–F16.5, F16.7–F16.9, F17.0, F17.3–F17.5, F17.7–F17.9, F18.0–F18.5, F18.7–F18.9, F19.0–F19.5, and F19.7–F19.9; Accidental poisoning by and exposure to drugs, medicaments and biological substances, X40–X44; Intentional self-poisoning (suicide) by and exposure to drugs, medicaments and biological substances, X60–X64; Assault (homicide) by drugs, medicaments and biological substances, X85; and Poisoning by and exposure to drugs, medicaments and biological substances, undetermined intent, Y10–Y14. Drug-induced causes exclude accidents, homicides, and other causes indirectly related to drug use. Also excluded are newborn deaths associated with mother’s drug use.

Codes for alcohol-induced deaths

Causes of death attributable to alcohol-induced mortality include ICD-10 codes F10, Mental and behavioral disorders due to alcohol use; G31.2, Degeneration of nervous system due to alcohol; G62.1, Alcoholic polyneuropathy; I42.6, Alcoholic cardiomyopathy; K29.2, Alcoholic gastritis; K70, Alcoholic liver disease; R78.0, Finding of alcohol in blood; X45, Accidental poisoning by and exposure to alcohol; X65, Intentional self-poisoning by and exposure to alcohol; and Y15, Poisoning by and exposure to alcohol, undetermined intent. Alcohol-induced causes exclude accidents, homicides, and other causes indirectly related to alcohol use. This category also excludes newborn deaths associated with maternal alcohol use.

Marital status

Age-specific and age-adjusted death rates by marital status are shown in [table 25](#) by sex. Mortality data by marital status is generally of high quality. A study of death certificate data using the 1986 National Mortality Followback Survey showed a high level of consistency in reporting marital status (47). Age-adjusted death rates by marital status were computed based on the age-specific rates and the standard population for ages 25 years and over. While

age-specific death rates by marital status are shown for the age group 15–24 years, they are not included in the computation of the age-adjusted rate because of their high variability, particularly for the widowed population. Also, the age groups 75–84 and 85 years and over are combined due to high variability in death rates in the 85 year and over age group, particularly for the never married population.

In previous reports of final mortality data, population estimates from the CPS were used to calculate death rates for marital status by race. Beginning in 2002, CPS respondents were given the option of choosing more than one racial group to identify themselves. Because mortality data for 2002 is not nationally available for racial categories comparable to those used in the CPS, population estimates are not available to calculate death rates for marital status by race. Therefore, mortality data by marital status showing race and Hispanic origin detail are not shown in this report. However, the number of deaths for 2002 by marital status for previously shown race and Hispanic origin categories are available on the 2002 mortality data set (see NCHS Web site at http://www.cdc.gov/nchs/products/elec_prods/subject/mortucd.htm.)

Educational attainment

Beginning with the 1989 data year, an item indicating decedent’s educational attainment was added to the certificates of numerous States. Mortality data on educational attainment for 2002 are based on deaths to residents of the 47 States and the District of Columbia whose data were approximately 80 percent or more complete on a place-of-occurrence basis. Data for Georgia, Rhode Island, and South Dakota were excluded because the item was not on their certificates.

Age-specific and age-adjusted death rates by educational attainment are shown in [table 26](#). Age-adjusted death rates by educational attainment were computed based on the age-specific rates and the standard population for ages 25–64 years. Data for age groups 65 years and over are not shown because reporting quality is poorer at older than younger ages (56).

Rates by educational attainment are affected by differences in measurement of education for the numerator and the denominator. The numerator is based on number of years of education completed as reported on the death certificate whereas the denominator is based on highest degree completed as reported on census surveys (57).

Injury at work

Information on deaths attributed to injuries at work is derived from a separate item on the death certificate that asks the medical certifier whether the death resulted from an injury sustained at work. The item is on the death certificate of all States. Number of deaths, age-specific death rates, and age-adjusted death rates for injury at work are shown in [tables 27](#) and [28](#). Deaths, crude death rates, and age-adjusted death rates for injury at work are shown for ages 15 years and over. Age-adjusted death rates for injury at work were computed using age-specific death rates and the U.S. standard population based on year 2000 standard for ages 15 years and over. See section on “[Computing rates](#).”

Infant mortality

Infant mortality rates are the most commonly used index for measuring the risk of dying during the first year of life. The rates

presented in this report are calculated by dividing the number of infant deaths in a calendar year by the number of live births registered for the same period and are presented as rates per 1,000 or per 100,000 live births. For final birth figures used in the denominator for infant mortality rates, see *Births: Final Data for 2002* (29). In contrast to infant mortality rates based on live births, infant death rates are based on the estimated population under 1 year of age. Infant death rates that appear in tabulations of age-specific death rates in this report are calculated by dividing the number of infant deaths by the July 1, 2002, population estimate of persons under 1 year of age, based on 2000 census populations. These rates are presented as rates per 100,000 population in this age group. Because of differences in the denominators, infant death rates may differ from infant mortality rates.

Maternal mortality

Maternal mortality rates are also computed on the basis of the number of live births. The maternal mortality rate indicates the likelihood of a pregnant woman dying of maternal causes. They are calculated by dividing the number of maternal deaths in a calendar year by the number of live births registered for the same period and are presented as rates per 100,000 live births. The number of live births used in the denominator is an approximation of the population of pregnant women who are at risk of a maternal death.

"Maternal deaths" are defined by the World Health Organization as "the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and the site of the pregnancy, from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes" (7). Included in these deaths are ICD-10 codes A34, O00–O95, and O98–O99.

Some State death certificates include a separate question regarding pregnancy status. A positive response to the question is interpreted as if "pregnant" was reported in Part II of the cause-of-death section of the death certificate. If a specified length of time is not provided by the medical certifier, it is assumed that the pregnancy terminated 42 days or less prior to death. Further, if only indirect maternal causes of death (i.e., a previously existing disease or a disease that developed during pregnancy which was not due to direct obstetric causes but was aggravated by physiologic effects of pregnancy) are reported in Part I and pregnancy is reported in either Part I or Part II, the death is classified as a maternal death.

Quality of reporting and processing cause of death

One index of the quality of reporting causes of death is the proportion of death certificates coded to Chapter XVIII; Symptoms, signs and abnormal clinical and laboratory findings, not elsewhere classified (ICD-10 codes R00–R99). Although deaths occur for which the underlying causes are impossible to determine, this proportion indicates the care and consideration given to the cause-of-death statement by the medical certifier. This proportion also may be used as a rough measure of the specificity of the medical diagnoses made by the certifier in various areas. The percent of all reported deaths in the United States assigned to Symptoms, signs and abnormal clinical and laboratory findings, not elsewhere classified, was 1.23 percent in 2002, lower than in 2000 and 2001 (1.33 and 1.34 percent,

respectively), but higher than the percent in 1999 (1.12 percent). From 1990 through 1999, the percent of deaths from this cause for all ages combined generally was fairly stable, between 1.08 and 1.18 percent.

Rules for coding a cause(s) of death may sometimes require modification when evidence suggests that such modifications will improve the quality of cause-of-death data. These changes, however, may affect comparability of data between years for select causes of death.

The large increase in Influenza (ICD-10 codes J10–J11) deaths from 2001 to 2002 is largely due to a change in the coding rules, which resulted in deaths that would have been assigned to Pneumonia in 2001, instead were assigned to Influenza in 2002.

Among the infant causes, the large increase in deaths from Newborn affected by maternal complications of pregnancy (maternal complications) (ICD-10 code P01) and the decrease in deaths from Atelectasis (ICD codes P28.0–P28.1) are partly due to a change in the coding rules, which resulted in deaths that would have previously been assigned to Atelectasis, instead were assigned to maternal complications in 2002.

Similarly, the large increase in Birth trauma (ICD-10 codes P10–P15) among infants for 2002, is largely due to a coding rule change, which resulted in deaths that would have previously been assigned to Neonatal aspiration syndromes (ICD-10 code P24), Pulmonary hemorrhage originating in the perinatal period (ICD-10 code P26), Neonatal hemorrhage (ICD-10 codes P50–P52,P54), or Other perinatal conditions (ICD-10 codes P29,P70.3–P70.99,P71–P76, P78–P81,P83.0–P83.1,P83.3–P93.9,P90–P96) instead were assigned Birth trauma in 2002.

Changes to the coding rules, such as those described above, are implemented when evidence suggests that the changes will improve the overall quality of the cause of death data. Such changes, however, may affect comparability of data for select causes of death between years.

Rare causes of death

Selected causes of death considered to be of public health concern are routinely confirmed by the States according to agreed upon procedures between the State vital statistics programs and the National Center for Health Statistics. These causes, termed "Infrequent and rare causes of death," are listed in the NCHS instruction manuals Parts 2a, 11, and 20 (37,58,59).

For data year 2002, complete confirmation of deaths from infrequent and rare causes was not provided by the District of Columbia and the following States: Alabama, California, Illinois, Minnesota, Mississippi, Nebraska, New York, Pennsylvania, Texas, and West Virginia.

Population bases for computing rates

Populations used for computing death rates and life tables shown in this report represent the population residing in the United States, enumerated as of April 1 for census years and estimated as of July 1 for all other years. Population estimates used to compute death rates for the United States for 2002 are shown by race for 10-year age groups in [table I](#) and are available by 5-year age groups on the mortality Web site at <http://www.cdc.gov/nchs/datawh/statab/unpubd/mortabs.htm> (60).

Population estimates in [table II](#) for Mexicans, Puerto Ricans, Cubans, and Other Hispanics, and population estimates by marital status in [table III](#), are based on the Current Population Survey adjusted to resident population control totals for the United States (61) and, as such, are subject to sampling variation (see “[Random variation](#)”). The control totals used are 2000-based population estimates for the United States for July 1, 2002 (60).

Population estimates by educational attainment, shown in [table IV](#), are also based on the Current Population Survey (61) adjusted to resident population control totals (61), and are also subject to sampling variation (see “[Random variation](#)”). The control totals used are 2000-based population estimates for 47 States and the District of Columbia for July 1, 2002 (60).

Population estimates for each State, shown in [table V](#), were estimated from State-level postcensal population estimates based on the 2000 census, estimated as of July 1, 2002 (60). Population estimates for Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas, also shown in [table V](#), are based on the 2000 census, estimated as of July 1, 2002 (62). Population estimates for each State and territory are based on demographic analysis and, therefore, are not subject to sampling variation.

Death rates, shown in this report, for 1991–2002 are based on populations that are consistent with the 2000 census levels (60,63–73). These estimates were produced under a collaborative arrangement with the U.S. Census Bureau and are based on the 2000 census counts by age, race, and sex, modified to be consistent with U.S. Office of Management and Budget racial categories as of 1977 and historical categories for death data (9). The modification procedures are described in detail elsewhere (11,12).

Computing rates

Except for infant and maternal mortality rates, rates are on an annual basis per 100,000 estimated population residing in the specified area. Infant and maternal mortality rates are per 1,000 or per 100,000 live births. Comparisons made in the text among rates, unless otherwise specified, are statistically significant at the 0.05 level of significance. Lack of comment in the text about any two rates does not mean that the difference was tested and found not to be significant at this level.

Age-adjusted rates (R') are used to compare relative mortality risks among groups and over time. However, they should be viewed as relative indexes rather than as actual measures of mortality risk. They were computed by the direct method, that is, by applying age-specific death rates (R_i) to the U.S. standard population (w_i) ([table VII](#)).

$$R' = \sum_i w_i R_i$$

Beginning with the 1999 data year, a new population standard was adopted by NCHS for use in age-adjusting death rates. Based on the projected year 2000 population of the United States, the new standard replaces the 1940 standard population that had been used for over 50 years. The new population standard affects levels of mortality and to some extent trends and group comparisons. Of particular note are the effects on race comparison of mortality. For detailed discussion see *Age Standardization of Death Rates: Implementation of the Year 2000 Standard* (74).

All age-adjusted rates shown in this report are based on the year 2000 standard population. The year 2000 standard population and

corresponding weights used for computing age-adjusted rates and standard errors, excluding those by marital status, education, injury at work, and the U.S. territories, are shown in [table VI](#).

Age-adjusted rates by marital status were computed by applying the age-specific death rates to the U.S. standard population for ages 25 years and over. Although age-specific death rates by marital status are shown for the age group 15–24 years, they are not included in the calculation of age-adjusted rates because of their high variability, particularly for the widowed population. Also, the age groups 75–84 and 85 years and over are combined because of high variability in death rates in the 85 years and over age group, particularly for the never married population. The year 2000 standard population and corresponding weights used for computing age-adjusted rates and standard errors by marital status are shown in [table VII](#).

Age-adjusted rates by educational attainment were computed by applying the age-specific death rates to the U.S. standard population for ages 25–64 years. Data for age groups 65 years and over are not shown because reporting quality is poorer for older than for younger ages (56). The year 2000 standard population and corresponding weights used for computing age-adjusted rates and standard errors by education are shown in [table VIII](#).

Age-adjusted rates for injury at work were computed by applying the age-specific death rates to the U.S. standard population for ages 15 years and over. The year 2000 standard population and corresponding weights used for computing age-adjusted rates and standard errors for injury at work are shown in [table IX](#).

Age-adjusted rates for Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas were computed by applying the age-specific death rates to the U.S. standard population. Age groups for 75 years and over were combined because population counts were unavailable by age group for ages over 75 years. The year 2000 standard population and corresponding weights used for computing age-adjusted rates and standard errors for the territories are shown in [table X](#).

Using the same standard population, death rates for the total population and for each race-sex group were adjusted separately. The age-adjusted rates were based on 10-year age groups. It is important not to compare age-adjusted death rates with crude rates.

Death rates for the Hispanic population are based only on events to persons reported as Hispanic. Rates for non-Hispanic white persons are based on the sum of all events to white decedents reported as non-Hispanic and white decedents with origin not stated. Hispanic origin is not imputed if it is not reported.

Random variation

The mortality data presented in this report, with the exception of data for 1972, are not subject to sampling error. In 1972 mortality data were based on a 50-percent sample of deaths because of resource constraints. Mortality data, even based on complete counts, may be affected by random variation. That is, the number of deaths that actually occurred may be considered as one of a large series of possible results that could have arisen under the same circumstances (75,76). When the number of deaths is small (perhaps less than 100), random variation tends to be relatively large. Therefore, considerable caution must be observed in interpreting statistics based on small numbers of deaths.

Table I. Estimated population by 10-year age groups, specified race and sex: United States, 2002

[Populations are postcensal estimates based on the 2000 census, estimated as of July 1, 2002; see "Technical Notes"]

SOURCE: Population estimates based on unpublished tabulations prepared by the Housing and Household Economic Statistics Division, U.S. Bureau of the Census. 2003.

Measuring random variability—To quantify the random variation associated with mortality statistics, one must make an assumption regarding the appropriate underlying distribution. Deaths, as infrequent events, can be viewed as deriving from a Poisson probability distribution. The Poisson distribution is simple conceptually and computationally, and provides reasonable, conservative variance estimates for mortality statistics when the probability of dying is relatively low (76). Using the properties of the Poisson distribution, the standard error (SE) associated with the number of deaths (D) is

$$1. \quad SE(D) = \sqrt{\text{var}(D)} = \sqrt{D}$$

where $\text{var}(D)$ denotes the variance of D .

The standard error associated with crude and age-specific death rates (R) assumes that the population denominator (P) is a constant and is

$$2. \quad SE(R) = \sqrt{\text{var}\left(\frac{D}{P}\right)} = \sqrt{\frac{1}{P^2} \text{var}(D)} = \sqrt{\frac{D}{P^2}} = \frac{R}{\sqrt{D}}$$

The coefficient of variation or relative standard error (RSE) is a useful measure of relative variation. The RSE is calculated by dividing the statistic (e.g., number of deaths, death rate) into its standard error and multiplying by 100. For the number of deaths

$$RSE(D) = 100 \frac{SE(D)}{D} = 100 \frac{\sqrt{D}}{D} = 100 \sqrt{\frac{1}{D}}$$

Table V. Estimated population for the United States, each State, Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas, 2002

[Populations for the United States are postcensal estimates produced in 2002 based on the 2000 census estimated as of July 1, 2002. Populations for each State, Puerto Rico, Virgin Islands, Guam, American Samoa, and Northern Marianas are postcensal estimates produced in 2003 based on the 2000 census estimated as of July 1, 2002. State populations do not add to U.S. total]

For crude and age-specific death rates

$$\text{RSE}(R) = 100 \frac{\text{SE}(R)}{R} = 100 \frac{R/\sqrt{D}}{R} = 100 \sqrt{\frac{1}{D}}$$

Thus,

$$3. \quad \text{RSE}(D) = \text{RSE}(R) = 100 \sqrt{\frac{1}{D}}$$

The standard error of the age-adjusted death rate (R') is

$$4. \quad \text{SE}(R') = \sqrt{\sum_i w_i^2 \text{var}(R_i)} = \sqrt{\sum_i \left\{ w_i^2 \left(\frac{R_i^2}{D_i} \right) \right\}}$$

where

R_i = age-specific rate for the i th age group

w_i = age-specific standard weight for the i th age group from the U.S. standard population such that $\sum w_i = 1.0$ (see [table VI](#) and age-adjusted death rate under "Definition of terms")

D_i = number of deaths for the i th age group

The RSE for the age-adjusted rate, $\text{RSE}(R')$, can easily be calculated by dividing $\text{SE}(R')$ from formula 4 by the age-adjusted death rate, R' , and multiplying by 100.

$$\text{RSE}(R') = 100 \frac{\text{SE}(R')}{R'}$$

For tables showing infant and maternal mortality rates based on live births (B) in the denominator, calculation of the standard error assumes random variability in both the numerator and denominator. The standard error for the infant mortality rate (IMR) is

$$5. \quad \text{SE}(IMR) = \sqrt{\frac{\text{var}(D) + IMR \cdot \text{var}(B)}{E(B)^2}} = \sqrt{\frac{D}{B^2} + \frac{D^2}{B^3}}$$

where the number of births, B , is also assumed to be distributed according to a Poisson distribution and $E(B)$ is the expectation of B .

The RSE for the IMR is

$$6. \quad \text{RSE}(IMR) = 100 \frac{\text{SE}(IMR)}{IMR} = 100 \sqrt{\frac{1}{D} + \frac{1}{B}}$$

For maternal mortality rates, formulas 5 and 6 may be used substituting the maternal mortality rate for the IMR .

Formulas 1-6 may be used for all tables presented in this report except for death rates and age-adjusted death rates shown in [tables 5, 25, and 26](#) that are calculated using population figures that are subject to sampling error (see the following subsection).

[Tables 5, 25, and 26](#)—Death rates for Mexicans, Puerto Ricans, Cubans, and Other Hispanics in [table 5](#), rates by marital status in [table 25](#) and rates by educational attainment in [table 26](#) are based on population estimates derived from the U.S. Bureau of the Census' Current Population Survey (CPS) for 2002 and adjusted to resident population control totals. As a result, the rates are subject to sampling variability in the denominator as well as random variability in the numerator.

For crude and age-specific death rates (R) the standard error is calculated as

$$7. \quad \text{SE}(R) = R \sqrt{\frac{1}{D} + 0.67 \left(a + \frac{b}{P} \right)}$$

For age-adjusted death rates (R')

$$8. \quad \text{SE}(R') = \sqrt{\sum_i \left\{ w_i^2 R_i^2 \left[\frac{1}{D_i} + 0.67 \left(a + \frac{b}{P_i} \right) \right] \right\}}$$

where a and b in formulas 7 and 8 represent parameters presented in [table XI](#), which are derived from the CPS data for 2001 and 2002 and vary depending on the subgroup of interest (77,78).

Suppression of unreliable rates—Beginning with 1989 data, an asterisk is shown in place of a crude or age-specific death rate based on fewer than 20 deaths, the equivalent of an RSE of 23 percent or more. The limit of 20 deaths is a convenient, if somewhat arbitrary, benchmark, below which rates are considered to be too statistically unreliable for presentation. For infant and maternal mortality rates, the same criterion (less than 20 deaths) is used to determine whether an asterisk is presented in place of the rate. For age-adjusted death rates the suppression criterion is based on the sum of the age-specific deaths; i.e., if the sum of the age-specific deaths is less than 20, an asterisk is presented in place of the rate. These procedures are used throughout this report except for death rates shown in [tables 5, 25, and 26](#).

For death rates shown in [tables 5, 25, and 26](#), sampling variability in the population denominator has a substantial impact on the overall variability in the rate. Therefore, the number of deaths in the numerator is not used as the sole suppression factor. RSEs for rates shown in [tables 5, 25, and 26](#) are derived from formulas 7 and 8 by dividing the results of formulas 7 and 8, by the crude/age-specific rate and age-adjusted rate, respectively, and multiplying by 100. Rates are replaced by asterisks if the calculated RSE is 23 percent or more. In some cases, for smaller population subgroups, the estimated sample population from the CPS may be zero, even though deaths are presented for these same subgroups. In these cases, the death rate is incalculable and is automatically replaced with an asterisk.

Confidence intervals and statistical tests based on 100 deaths or more—When the number of deaths is large, a normal approximation may be used in the calculation of confidence intervals and statistical tests. How large is to some extent a subjective judgment. In general, for crude and age-specific death rates and for infant and maternal mortality rates, the normal approximation performs quite well when the

... Category not applicable.

number of deaths is 100 or greater. For age-adjusted rates, the criterion for use of the normal approximation is somewhat more complicated (6,74,79). Formula 9 is used to calculate 95-percent confidence limits for the death rate when the normal approximation is appropriate.

$$9. \quad L(R) = R - 1.96(\text{SE}(R)) \text{ and } U(R) = R + 1.96(\text{SE}(R))$$

where $L(R)$ and $U(R)$ are the lower and upper limits of the confidence interval, respectively. The resulting 95-percent confidence interval can be interpreted to mean that the chances are 95 in 100 that the "true" death rate falls between $L(R)$ and $U(R)$. For example, suppose that the crude death rate for Malignant neoplasms is 193.2 per 100,000 population based on 557,271 deaths. Lower and upper 95-percent confidence limits using formula 9 are calculated as

$$\begin{aligned} L(193.2) &= 193.2 - 1.96(.26) = 192.7 \\ U(193.2) &= 193.2 + 1.96(.26) = 193.7 \end{aligned}$$

Thus, the chances are 95 in 100 that the true death rate for malignant neoplasms is between 192.7 and 193.7. Formula 9 can also be used to calculate 95-percent confidence intervals for the number of deaths, age-adjusted death rates, infant mortality rates, and other mortality statistics when the normal approximation is appropriate by replacing R with D , R' , IMR , etc.

When testing the difference between two rates, R_1 and R_2 (each based on 100 or more deaths), the normal approximation may be used to calculate a test statistic, z , such that

$$10. \quad z = \frac{R_1 - R_2}{\sqrt{\text{SE}(R_1)^2 + \text{SE}(R_2)^2}}$$

If $|z| \geq 1.96$ then the difference between the rates is statistically significant at the 0.05-level. If $|z| < 1.96$ then the difference is not statistically significant. Formula 10 can also be used to perform tests for other mortality statistics when the normal approximation is appropriate (when both statistics being compared meet the normal criteria) by replacing R_1 and R_2 with D_1 and D_2 , R'_1 and R'_2 , etc. Suppose that the female age-adjusted death rate for Malignant neoplasms of trachea, bronchus, and lung (lung cancer) is 41.0 per 100,000 U.S. standard population in 2001 (R_1) and 41.6 per 100,000

U.S. standard population in 2002 (R_2). The standard error for each of these figures, $\text{SE}(R_1)$ and $\text{SE}(R_2)$, is calculated using formula 4. Using formula 10, one can test if the increase in the age-adjusted rate is statistically significant.

$$z = \frac{41.0 - 41.6}{\sqrt{(0.163)^2 + (0.161)^2}} = -2.62$$

Because $|z| = 2.62 > 1.96$, the increase from 2001 to 2002 in the female age-adjusted death rate for lung cancer is statistically significant.

Confidence intervals and statistical tests based on less than 100 deaths—When the number of deaths is not large (less than 100), the Poisson distribution cannot be approximated by the normal distribution. The normal distribution is a symmetric distribution with a range from $-\infty$ to $+\infty$. As a result, confidence intervals based on the normal distribution also have this range. The number of deaths or the death rate, however, cannot be less than zero. When the number of deaths is very small, approximating confidence intervals for deaths and death rates using the normal distribution will sometimes produce lower confidence limits that are negative. The Poisson distribution, in contrast, is an asymmetric distribution with zero as a lower bound. Thus, confidence limits based on this distribution will never be less than zero. A simple method based on the more general family of gamma distributions, of which the Poisson is a member, can be used to approximate confidence intervals for deaths and death rates when the number of deaths is small (74,79). For more information regarding how the gamma method is derived, see *Derivation of the gamma method* at the end of this section.

Calculations using the gamma method can be made using commonly available spreadsheet programs or statistical software (e.g., Excel, SAS) that include an inverse gamma function. In Excel, the function "gammainv(probability, alpha, beta)" returns values associated with the inverse gamma function for a given probability between 0 and 1. For 95 percent confidence limits, the probability associated with the lower limit is $.05/2=.025$ and the probability associated with the upper limit is $1-(.05/2)=.975$. Alpha and beta are parameters associated with the gamma distribution. For the number of deaths and crude and

age-specific death rates, alpha=D (the number of deaths) and beta=1. In Excel, the following formulas can be used to calculate lower and upper 95 percent confidence limits for the number of deaths and crude and age-specific death rates

$$L(D) = \text{GAMMAINV}(.025, D, 1) \text{ and } U(D) = \text{GAMMAINV}(.975, D+1, 1)$$

Confidence limits for the death rate are then calculated by dividing $L(D)$ and $U(D)$ by the population (P) at risk of dying (see formula 17).

Alternatively, 95 percent confidence limits can be estimated using the lower and upper confidence limit factors shown in [table XII](#). For the

number of deaths, D , and the death rate, R ,

$$11. L(D) = L \times D \text{ and } U(D) = U \times D$$

$$12. L(R) = L \times R \text{ and } U(R) = U \times R$$

where L and U in formulas 11 and 12 are the lower and upper confidence limit factors which correspond to the appropriate number of deaths, D , in [table XII](#). For example, suppose that the death rate for American Indian females aged 10–14 is 22.5 per 100,000 and based on 34 deaths. Applying formula 12, values for L and U from

Table XII. Lower and upper 95-percent confidence limit factors for the number of deaths and death rate when the number of deaths is less than 100

table XII for 34 deaths are multiplied by the death rate, 22.5, such that

$$L(R) = L(22.5) = 0.692529 \times 22.5 = 15.6$$

$$U(R) = U(22.5) = 1.397400 \times 22.5 = 31.4$$

These confidence limits indicate that the chances are 95 out of 100 that the actual death rate for American Indian females aged 10–14 is between 15.6 and 31.4 per 100,000.

Although the calculations are similar, confidence intervals based on small numbers for age-adjusted death rates, infant and maternal mortality rates, and rates that are subject to sampling variability in the denominator are somewhat more complicated (6,74). Refer to the most recent version of the Mortality Technical Appendix for more details (<http://www.cdc.gov/nchs/datawh/statab/pubd/ta.htm>).

When comparing the difference between two rates, R_1 and R_2 , where one or both of the rates are based on fewer than 100 deaths, a comparison of 95-percent confidence intervals may be used as a statistical test. If the 95-percent confidence intervals do not overlap, then the difference can be said to be statistically significant at the 0.05-level. A simple rule of thumb is: if $R_1 > R_2$ then test if $L(R_1) > U(R_2)$ or if $R_2 > R_1$ then test if $L(R_2) > U(R_1)$. Positive tests denote statistical significance at the 0.05-level. For example, suppose that American Indian females aged 10–14 have a death rate (R_1) of 22.5 based on 34 deaths and Asian and Pacific Islander (API) females aged 10–14 have a death rate (R_2) of 11.3 per 100,000 based on 49 deaths. The 95-percent confidence limits for R_1 and R_2 calculated using formula 12 would be

$$L(R_1) = L(22.5) = 0.692529 \times 22.5 = 15.6$$

$$U(R_1) = U(22.5) = 1.397400 \times 22.5 = 31.4$$

$$L(R_2) = L(11.3) = 0.739806 \times 11.3 = 8.4$$

$$U(R_2) = U(11.3) = 1.322053 \times 11.3 = 14.9$$

Because $R_1 > R_2$ and $L(R_1) > U(R_2)$, it can be concluded that the difference between the death rates for American Indian females 10–14 and API females of the same age is statistically significant at the 0.05-level. That is, taking into account random variability, API females 10–14 have a death rate that is significantly lower than that for American Indian females of the same age.

This test may also be used to perform tests for other statistics when the normal approximation is not appropriate for one or both of the statistics being compared by replacing R_1 and R_2 with D_1 and D_2 , R'_1 and R'_2 , etc.

Users of the method of comparing confidence intervals should be aware that this method is a conservative test for statistical significance. That is, the difference between two rates may, in fact, be statistically significant even though confidence intervals for the two rates overlap (80). Thus, caution should be observed when interpreting a non-significant difference between two rates, especially when the lower and upper limits being compared overlap only slightly.

Derivation of the gamma method—For a random variable X that follows a gamma distribution $\Gamma(y,z)$, where y and z are the parameters that determine the shape of the distribution, $E(X) = yz$ and $Var(X) = yz^2$ (81). For the number of deaths, D , $E(D) = D$ and $Var(D) = D$. It follows that $y = D$ and $z = 1$ and thus,

$$13. \quad D \sim \Gamma(D,1)$$

From equation 13, it is clear that the shape of the distribution of deaths depends only on the number of deaths.

For the death rate, R , $E(R) = R$ and $Var(R) = D/P^2$. It follows, in this case, that $y = D$ and $z = P^{-1}$ and thus,

$$14. \quad R \sim \Gamma(D, P^{-1}).$$

A useful property of the gamma distribution is that for $X \sim \Gamma(y,z)$, one can divide X by z such that $X/z \sim \Gamma(y,1)$. This converts the gamma distribution into a simplified, standard form dependent only on parameter y . Expressing equation 14 in its simplified form gives

$$15. \quad \frac{R}{P^{-1}} = D \sim \Gamma(D,1)$$

From equation 15, it is clear that the shape of the distribution of the death rate is also dependent solely on the number of deaths.

Using the results of equations 13 and 15, one can use the inverse gamma distribution to calculate upper and lower confidence limits. Lower and upper 100(1 – α) percent confidence limits for the number of deaths, $L(D)$ and $U(D)$, are estimated as

$$16. \quad L(D) = \Gamma^{-1}_{(D,1)}(\alpha/2) \text{ and } U(D) = \Gamma^{-1}_{(D+1,1)}(1-\alpha/2)$$

where Γ^{-1} represents the inverse of the gamma distribution and $D + 1$ in the formula for $U(D)$ reflects a continuity correction made necessary by the fact that D is a discrete random variable and the gamma distribution is a continuous distribution. For a 95-percent confidence interval, $\alpha = .05$. For the death rate, it can be shown that

$$17. \quad L(R) = \frac{L(D)}{P} \text{ and } U(R) = \frac{U(D)}{P}$$

For more detail regarding the derivation of the gamma method and its application to age-adjusted death rates and other mortality statistics, see references 6, 74, and 79.

Availability of mortality data

Mortality data are available in publications, unpublished tables, and electronic products as described on the mortality Web site at the following address: <http://www.cdc.gov/nchs/about/major/dvs/mordata.htm>. More detailed analysis than provided in this report is possible by using the Mortality public-use data set issued each data year. Since 1991 the data set is available through NCHS in CD-ROM format. Data are also available in the *Vital Statistics of the United States, Mortality, and Vital and Health Statistics*, Series 20 reports, and the *National Vital Statistics Reports* through NCHS.

Definitions of terms

Infant deaths—Deaths of infants aged under 1 year.

Neonatal deaths—Deaths of infants aged 0–27 days.

Postneonatal deaths—Deaths of infants aged 28 days–1 year.

Crude death rate—Total deaths per 100,000 population for a specified period. The crude death rate represents the average chance of dying during a specified period for persons in the entire population.

Age-specific death rate—Deaths per 100,000 population in a specified age group, such as 1–4 years or 5–9 years for a specified period.

Age-adjusted death rate—The death rate used to make comparisons of relative mortality risks across groups and over time. This rate should be viewed as a construct or an index rather than as a direct or actual measure of mortality risk. Statistically, it is a weighted average of the age-specific death rates, where the weights represent the fixed population proportions by age (82).
