#### Abstract

We present a Delaunay refinement algorithm for meshing a piecewise smooth complex in three dimensions. The algorithm protects edges with weighted points to avoid the difficulty posed by small angles between adjacent input elements. These weights are chosen to mimic the local feature size and to satisfy a Lipschitzlike property. A Delaunay refinement algorithm using the weighted Voronoi diagram is shown to terminate with the recovery of the topology of the input. Guaranteed bounds on the aspect ratios, normal variation, and dihedral angles are also provided. To this end, we present new concepts and results including a new definition of local feature size and a proof for a generalized topological ball property.

Keywords Delaunay refinement • Mesh generation • Piecewise smooth complex • Topology

## 1 Introduction

Delaunay refinement for meshing domains has been around for more than a decade now $[15,16,31,32]$. However, an algorithm that handles input as general as piece-

[^0]wise smooth complexes (PSC) is still lacking. There is a need in solid modeling to represent objects that are dimensionally or materially inhomogeneous [29]. For example, in a part consisting of different materials, the internal boundaries may meet to form a non-manifold. A boundary representation is essentially a graph in which the nodes represent the vertices, edges, and faces in the object, and the links represent the incidence relation [23]. Such a representation is a PSC when the curved segments called edges and the smooth surface patches called faces meet properly. The boundary of any solid with smooth faces and sharp junctions is a special case where the PSC is a 2-manifold.

As opposed to the polyhedral domains, topology recovery becomes a nontrivial issue for domains with curved elements since the output cannot conform to the input exactly. Some recent works address this issue by developing a Delaunay refinement strategy whose design and analysis are driven by topological property violations [7, $14,20]$. These algorithms work on the assumption that the input is a smooth surface or a surface that approximates a smooth surface.

To handle PSC one has to deal with non-smoothness. On top of it, possible small angles between the curved elements add further difficulty. The menace of small angles in Delaunay meshing is well known [17, 26, 33]. Although solutions for polyhedral domains have been obtained recently [11, 12, 28], the case for curved domains remains mostly open except for a recent work by Boissonnat and Oudot [8]. They showed that a class of surfaces called Lipschitz surfaces can be meshed with a Delaunay refinement strategy as long as the input angles are sufficiently large. Unfortunately, the derived angle bound allows only a very restricted class of non-smooth surfaces and the case of PSC which includes non-manifolds remains open. Recently, Rineau and Yvinec [30] proposed a method to mesh volumes bounded by piecewise smooth surfaces under the constraint that the tangents to the surface subtend large input angles at non-smooth regions.

In this paper we present an algorithm to mesh PSC with Delaunay refinement without any constraint on input angles. One notable aspect of our algorithm is that, unlike previous approaches [8, 20], it respects the input "non-smooth features" as it meshes the input curves and vertices with 1-complexes.

One difficulty in meshing PSC stems from the fact that the usual local feature size definitions fail to provide an upper bound on the number of repeated insertions triggered by topological ball property violations. We overcome this problem by a new definition of local feature size which does not vanish on the domain. It is reminiscent of the effort in [10] where a non-vanishing local feature size is defined for compact sets in the context of surface reconstruction. Here we combine the two classical definitions, one based on the medial axis [2] and the other based on the adjacency of elements [11, 31]. The non-smooth regions are then protected by balls whose sizes and placements are guided by a simulation of a Lipschitz property. The Delaunay refinement is run on the weighted Voronoi diagram where the protecting balls are treated as weighted points. The protected curves in PSC always appear as a union of edges of the restricted weighted Delaunay triangulation. This helps the triangulations, restricted to the individual smooth surface patches, match seamlessly. It also preserves non-smooth features in the output, a concern that is important in various applications. An extended topological ball property [21] for general topological spaces
is proved to claim homeomorphism between the input and output. It is noteworthy that our weighted point approach never inserts a point inside the protecting balls. This eliminates the check for point insertions inside the protecting balls as well as the exception handler for such events.

### 1.1 Notation and Domain

Throughout this paper, we assume a generic intersection property that a $k$-manifold $\sigma \subset \mathbb{R}^{3}, 0 \leqslant k \leqslant 3$, and a $j$-manifold $\sigma^{\prime} \subset \mathbb{R}^{3}, 0 \leqslant j \leqslant 3$, intersect (if at all) in a ( $k+$ $j-3$ )-manifold if $\sigma \not \subset \sigma^{\prime}$ and $\sigma^{\prime} \not \subset \sigma$. We will use both geometric and topological versions of closed balls. A geometric closed ball centered at point $x \in \mathbb{R}^{3}$ with radius $r>0$ is denoted as $B(x, r)$. We use int $\mathbb{X}$ and bd $\mathbb{X}$ to denote the interior and boundary of a topological space $\mathbb{X}$, respectively. Given a complex $\mathbb{A}$, we use $|\mathbb{A}|$ to denote its underlying space.

The domain $\mathcal{D}$ is a PSC where each element is a compact subset of a $C^{3}$-smooth $k$-manifold, $0 \leqslant k \leqslant 2$. Each element is closed and hence contains its boundaries. We use $\mathcal{D}_{k}$ to denote the subset of all $k$-dimensional elements. $\mathcal{D}_{0}$ is a set of vertices; $\mathcal{D}_{1}$ is a set of curves called 1-faces; $\mathcal{D}_{2}$ is a set of surface patches called 2 -faces. For $1 \leqslant k \leqslant 2$, we use $\mathcal{D}_{\leqslant k}$ to denote $\bigcup_{j=0}^{k} \mathcal{D}_{j}$. Two elements are adjacent if their intersection is nonempty. Two elements $\sigma$ and $\tau$ are incident if $\tau \subseteq \operatorname{bd} \sigma$.

The domain $\mathcal{D}$ satisfies the usual requirements for being a complex: (i) interiors of the elements are pairwise disjoint; (ii) for any $\sigma \in \mathcal{D}, \operatorname{bd} \sigma$ is a union of elements in $\mathcal{D}$; (iii) for any $\sigma, \tau \in \mathcal{D}$, either $\sigma \cap \tau=\emptyset$ or $\sigma \cap \tau$ is a union of elements in $\mathcal{D}$.

For each 2 -face $\sigma$, we assume that $\sigma$ is part of a smooth compact surface $\Sigma$ without boundary whose equation is given and that $\sigma$ is represented using the equation of $\Sigma$ and some additional inequalities so that one can test whether a given point lies on $\sigma$. We also assume that $\mathrm{bd} \sigma$ consists of disjoint simple closed curves (no boundary points). For each 1 -face $\sigma$, we assume that $\sigma$ is an open curve (has boundary points) contained in the intersection of two surfaces $\Sigma_{1}$ and $\Sigma_{2}$ whose equations are also given and that $\sigma$ is represented using the equations of $\Sigma_{1}$ and $\Sigma_{2}$ as well as some additional inequalities so that one can test whether a given point lies on $\sigma$. We introduce the notation mani $(\sigma)$ : if $\sigma$ is a 1 -face, $\operatorname{mani}(\sigma)$ denotes $\Sigma_{1} \cap \Sigma_{2}$; if $\sigma$ is a 2-face, $\operatorname{mani}(\sigma)$ denotes $\Sigma$.

For any 2 -face $\sigma$ and for any point $x \in \operatorname{mani}(\sigma)$, we use $n_{\sigma}(x)$ to denote the unit outward normal to $\operatorname{mani}(\sigma)$ at $x$. For any 1 -face $\sigma$ and for any point $x \in \operatorname{mani}(\sigma)$, $n_{\sigma}(x)$ denotes the plane orthogonal to $\operatorname{mani}(\sigma)$ at $x$.

Given two nonzero vectors $\vec{d}_{1}$ and $\vec{d}_{2}$, let $\angle \vec{d}_{1}, \vec{d}_{2}$ denote the angle between them (which lies in the range $[0, \pi]$ ). Given a 1 - or 2 -dimensional linear subset $L$ in an Euclidean space and the vector $\vec{d}$, let $\angle \vec{d}, L$ denote the non-obtuse angle between $\vec{d}$ and the support line/plane of $L$. Similarly, given $L_{1}$ and $L_{2}$ where $L_{i}$ is a 1- or 2dimensional linear subset of an Euclidean space, let $\angle L_{1}, L_{2}$ denote the non-obtuse angle between the support line/plane of $L_{1}$ and the support line/plane of $L_{2}$.

Notice that our definition of PSC disallows certain kinds of surfaces such as cones or non-orientable surfaces, since they cannot be extended to a smooth surface without boundary. Although we have not included three-dimensional faces in the PSC definition, our algorithm can be extended to handle such a PSC using an approach similar to $[27,30]$. We avoid them for saving further technicalities and analysis.

Various data structures have been proposed in the computer-aided design literature in order to capture the combinatorial structure of non-manifold solid models; for example, see $[9,18,23]$. Any of these data structures can be used to represent our input PSC with each element tagged with the corresponding equations. It is popular for surfaces to be represented parametrically by rational functions in computer aided design (e.g., NURBS). Given such a representation, we can first implicitize the surfaces using the algorithm by Manocha and Canny [24] and then run our meshing algorithm.

### 1.2 Overview

Our strategy is to run Delaunay refinement as long as the topology of the domain is not recovered. Such a strategy was used to mesh smooth surfaces [14] where each insertion was triggered by a violation of topological ball property [21] (TBP). First of all, we cannot use the TBP for manifolds here since we are dealing with PSC. It turns out that the extended topological ball property which can ensure topology recovery for PSC [21] requires TBP for each element in $\mathcal{D}$. One may drive the refinement with the violation of the extended TBP, but the possible presence of small angles in the input causes difficulty. As a remedy, we protect the vertices and 1-faces with some geometric balls so that no point is inserted in these protecting balls. Such a protection strategy made the Delaunay refinement possible for polyhedral domains with small angles [11, 12, 28]. However, placing the protecting balls of appropriate size seems to be far more difficult in the case of PSC. Once the balls are computed, we treat them as weighted points which bring the weighted Voronoi and weighted Delaunay diagrams into picture.

For a weighted point set $S \subset \mathbb{R}^{3}$, let $\operatorname{Vor} S$ and $\operatorname{Del} S$ denote the weighted Voronoi diagram and the weighted Delaunay triangulation of $S$, respectively. Vor $S$ and $\operatorname{Del} S$ are cell complexes, where each $k$-face in $\operatorname{Vor} S$ is a $k$-polytope and each $k$-face in Del $S$ is a $k$-simplex. Each $k$-face in Vor $S$ is dual to a $(3-k)$-face in Del $S$ and vice versa. We say that $S$ has the TBP for an element in $\mathcal{D}_{i}$ if this element intersects any $k$-face in Vor $S$ in either an empty set or a closed topological ball of dimension ( $i+k-3$ ).

If an element in the domain does not satisfy the TBP, our algorithm detects it and computes a point far away from all other existing points. At termination, which is guaranteed by a standard packing argument, $S$ has the TBP for each element in $\mathcal{D}$.

The entire analysis and the crucial step of ball protection needs a feature size definition which is 1-Lipschitz and nonzero everywhere. We achieve it by a nontrivial combination of the local feature sizes defined for polyhedral domains and smooth surfaces.

### 1.3 Background Results

We state a few technical results whose proofs are deferred to Appendix A.
Lemma 1.1 Let $E$ be the set of elements in $\mathcal{D}$ containing a point $x$. Let $B(x, r)$ be a ball such that for any $\sigma \in E, B(x, r) \cap \operatorname{mani}(\sigma)$ is a closed ball of dimension $\operatorname{dim}(\sigma)$. Then, for any $\sigma \in E$,
(i) if $\sigma$ is a 1-face, $B(x, r) \cap \sigma$ is an open curve (topological interval);
(ii) if $\sigma$ is a 2-face and every 1-face of $\sigma$ intersecting $B(x, r)$ contains $x$, then $B(x, r) \cap \sigma$ is a topological disk.

Lemma 1.2 Let $\sigma$ be a 2-face. Let $B(x, r)$ be a ball for some point $x \in \operatorname{mani}(\sigma)$ such that for any point $z \in B(x, r) \cap \operatorname{mani}(\sigma), \angle n_{\sigma}(x), n_{\sigma}(z)<\theta$ for some $\theta \leqslant \pi / 8$. Let $B \subset B(x, r)$ be a ball centered at a point $y \in B(x, r) \cap \operatorname{mani}(\sigma)$. For any plane $H$ containing $y$ such that $\angle n_{\sigma}(x), H<\theta, H \cap B \cap \operatorname{mani}(\sigma)$ is an open curve.

Lemma 1.3 Let $\sigma$ be a 1- or 2-face. Let $B(x, r)$ be a ball for some point $x \in \operatorname{mani}(\sigma)$ such that for any point $z \in B(x, r) \cap \operatorname{mani}(\sigma), \angle n_{\sigma}(x), n_{\sigma}(z)<\theta$ for some $\theta<\pi / 2$.
(i) If $\sigma$ is a 1 -face and $B(x, r) \cap \operatorname{mani}(\sigma)$ is connected, then for any points $y, z \in$ $B(x, r) \cap \operatorname{mani}(\sigma), \angle n_{\sigma}(x), y z>\pi / 2-\theta$.
(ii) If $\sigma$ is a $2-\mathrm{face}, \theta \leqslant \pi / 8$, and $B\left(x, \frac{1}{3} r\right) \cap \operatorname{mani}(\sigma)$ is connected, then for any points $y, z \in B\left(x, \frac{1}{3} r\right) \cap \operatorname{mani}(\sigma), \angle n_{\sigma}(x), y z>\pi / 2-\theta$.

## 2 Feature Size

We propose a definition of local feature size for PSC and establish several geometrical and topological properties. The local feature size and the properties will be useful in analyzing our meshing algorithm. As in the case of meshing smooth closed surfaces, it is hard to compute the local feature size at points in a PSC. Therefore, we propose a computable alternative for points on 1-faces. Our algorithm uses this computable alternative to construct balls to protect the vertices and 1-faces before running Delaunay refinement.

### 2.1 Local Feature Size

For any point $x$ on an element $\sigma \in \mathcal{D}$, define $m_{\sigma}(x)$ to be the distance between $x$ and the medial axis of $\operatorname{mani}(\sigma)$. Take $m_{\sigma}(x)=\infty$ if $\sigma$ is a vertex. It is well known that $m_{\sigma}$ is 1-Lipschitz, i.e., for any points $x, y \in \sigma, m_{\sigma}(x) \leqslant m_{\sigma}(y)+\|x-y\|$. Define $m(x)=\min \left\{m_{\sigma}(x): x \in \sigma\right\}$. Notice that $m$ may not be continuous. For example, for a 2-face $\sigma$, only the medial axis of mani $(\sigma)$ contributes to $m(x)$ when $x \in \operatorname{int} \sigma$, but more than one medial axis may contribute to $m(x)$ when $x \in \operatorname{bd} \sigma$. We also employ the local gap size $g(x)$ used in [11] to deal with small input angles: for any point $x \in|\mathcal{D}|, g(x)$ is the minimum $r>0$ such that $B(x, r)$ intersects two elements of $\mathcal{D} \leqslant 2$, one of which does not contain $x$.

Definition 2.1 For any point $x \in|\mathcal{D}|$, define $f(x)=\min \{m(x), g(x)\}$.
Lemma 2.1 For any 1- or 2-face $\sigma$, the following properties hold.
(i) For any point $x \in \sigma$,
(a) if $B$ is a ball tangent to mani $(\sigma)$ at $x$ and $\operatorname{radius}(B)<f(x)$, then $\sigma \cap \operatorname{int} B=$ Ø;
(b) if $r<f(x)$, then $B(x, r) \cap \operatorname{mani}(\sigma)$ and $B(x, r) \cap \sigma$ are closed balls of dimension $\operatorname{dim}(\sigma)$.
(ii) For any points $x, y \in \operatorname{mani}(\sigma)$, if $\|x-y\| \leqslant \mu f(x)$ for some $\mu \leqslant 1 / 3$, then $\angle n_{\sigma}(x), n_{\sigma}(y) \leqslant \mu /(1-\mu)$.

Proof Because $f(x) \leqslant m_{\sigma}(x)$, (i)(a) follows from standard results in the theory of $\varepsilon$-sampling [2, 4, 19]. Since $r<f(x) \leqslant m(x)$, it is known that $B(x, r) \cap \operatorname{mani}(\tau)$ is a closed ball of dimension $\operatorname{dim}(\tau)$ for all faces $\tau$ containing $x$ [19]. Coupled with the fact that $r<f(x) \leqslant g(x)$, Lemma 1.1 can be invoked to imply (i)(b). Since $f(x) \leqslant m_{\sigma}(x)$, (ii) follows from the standard normal variation result; see [3].

The function $f$ is not continuous because $m$ and $g$ may not be continuous. The value of $m(x)$ may change discontinuously when a point $x$ moves from a 2-face to an adjacent 1 -face because the distance to the medial axis of the 1 -face suddenly enters into the minimization in the definition of $m(x)$. If a point $x$ moves from a 1 - or 2-face to an adjacent face of lower dimension, the value of $g(x)$ approaches zero by definition. This makes $g$ discontinuous because $g(x)$ is strictly positive at the 0 -faces. Still, $f, g$ and $m$ are 1-Lipschitz in a restricted sense.

Lemma 2.2 For any $\sigma \in \mathcal{D}$, the functions $f, g$, and $m$ are 1-Lipschitz over int $\sigma$.
Proof The lemma is trivial for the vertices of $\mathcal{D}$. Let $\sigma$ be a 1- or 2-face. Take any two points $x, y \in \operatorname{int} \sigma$. Since $x, y \in \operatorname{int} \sigma$, they belong to the same set of elements of $\mathcal{D}$, which we denote as $E$. So $m(y)+\|x-y\|=\min _{\tau \in E}\left\{m_{\tau}(y)+\|x-y\|\right\} \geqslant$ $\min _{\tau \in E} m_{\tau}(x)=m(x)$, proving that $m$ is 1-Lipschitz over int $\sigma$. By definition, $B(y, g(y))$ intersects another element $\tau$ not containing $y$. Since $B(y, g(y))$ is contained inside $B(x, r)$, where $r=\|x-y\|+g(y), B(x, r)$ intersects both $\sigma$ and $\tau$. As $x \in \operatorname{int} \sigma, x \notin \tau$. It follows that $g(x) \leqslant r=g(y)+\|x-y\|$, proving that $g$ is 1-Lipschitz over int $\sigma$. Finally, $f(y)+\|x-y\|=\min \{m(y)+\|x-y\|, g(y)+$ $\|x-y\|\} \geqslant \min \{m(x), g(x)\}=f(x)$. So $f$ is 1-Lipschitz over int $\sigma$.

The function $f$ is close to being a local feature size function for $\mathcal{D}$. It blends the definition of local feature sizes of closed surfaces, which are used in meshing smooth surfaces [7, 14], and the definition of local gap sizes of polyhedral domains, which are used in polyhedral meshing [11,17] in the presence of small angles. The blending enables us to take care of both types of geometries in $\mathcal{D}$ : smooth surfaces meeting sharply at vertices and curves. The problem is that $f$ is only 1-Lipschitz within the interior of an element in $\mathcal{D}$. As a remedy, we propagate the value of $f$ from bd $\left|\mathcal{D}_{i}\right|$ to int $\left|\mathcal{D}_{i}\right|$ in order to define our local feature size function. We introduce a parameter $\delta \in(0,1)$ to control the extent of the propagation. The local feature size function $\operatorname{lfs}_{\delta}:|\mathcal{D}| \rightarrow \mathbb{R}$ is defined as follows.

Definition 2.2 For any $\delta \in(0,1]$ and for any point $x \in|\mathcal{D}|$,

$$
\operatorname{lfs}_{\delta}(x)=\left\{\begin{array}{l}
\delta f(x) \quad \text { if } x \in\left|\mathcal{D}_{0}\right| \\
\max \left\{\delta f(x), \max _{y \in \operatorname{bd} \sigma}\{\delta f(y)-\|x-y\|\}\right\} \\
\text { if } x \in \operatorname{int} \sigma \text { for some } \sigma \in \mathcal{D}_{1} \cup \mathcal{D}_{2}
\end{array}\right.
$$

Roughly speaking, we design $\mathrm{lfs}_{\delta}(x)$ so that if $x$ lies on a face $\sigma$ and is sufficiently far away from $\operatorname{bd} \sigma, \operatorname{lfs}_{\delta}(x)$ is equal to $\delta f(x)$. Indeed, if $\|x-y\|<\delta f(y)$ for some point $y \in \operatorname{bd} \sigma$, then $\delta f(y)-\|x-y\|>0$, and so it is possible for $\operatorname{lfs}_{\delta}(x)$ to be equal to $\max _{y \in \operatorname{bd} \sigma}\{\delta f(y)-\|x-y\|\}$. On the other hand, if $\|x-y\| \geqslant \delta f(y)$ for any point $y \in \operatorname{bd} \sigma, \max _{y \in \operatorname{bd} \sigma}\{\delta f(y)-\|x-y\|\}$ is nonpositive, and so $\operatorname{lfs}_{\delta}(x)=\delta f(x)$. The maximization $\left.\max _{y \in \operatorname{bd} \sigma}\{\delta f(y)-\|x-y\|\}\right\}$ is employed in the definition to help making lfs ${ }_{\delta} 1-$ Lipschitz. Similar maximizations and minimizations have been used before in obtaining Lipschitz functions [1, 22, 35]. The next result shows that lfs $\delta$ is indeed 1-Lipschitz.

Lemma 2.3 lfs $_{\delta}$ is 1-Lipschitz.
Proof Take any points $x, y \in|\mathcal{D}|$. Let $\sigma_{x}$ and $\sigma_{y}$ be the elements of $\mathcal{D}$ such that $x \in \operatorname{int} \sigma_{x}$ and $y \in \operatorname{int} \sigma_{y}$. (When $x$ is a vertex, $x=\sigma_{x}$. The same is true for $y$.)

Suppose that $y \in \sigma_{x}$. So $\sigma_{y}=\sigma_{x}$ or $\sigma_{y} \subset \operatorname{bd} \sigma_{x}$. We claim that $\operatorname{lfs}_{\delta}(x) \geqslant \delta f(y)-$ $\|x-y\|:$ if $y \in \operatorname{bd} \sigma_{x}, \operatorname{lfs}_{\delta}(x) \geqslant \delta f(y)-\|x-y\|$ by definition; if $y \in \operatorname{int} \sigma_{x}, \operatorname{lfs}_{\delta}(x) \geqslant$ $\delta f(x)>\delta f(y)-\|x-y\|$ by Lemma 2.2. By our claim, if lfs $\delta(y)=\delta f(y)$, we have $\operatorname{lfs}_{\delta}(x) \geqslant \operatorname{lfs}_{\delta}(y)-\|x-y\|$. Otherwise, $\operatorname{lfs}_{\delta}(y)=\delta f(z)-\|y-z\|$ for some point $z \in \operatorname{bd} \sigma_{y} \subseteq \operatorname{bd} \sigma_{x}$. By definition, $\operatorname{lfs}_{\delta}(x) \geqslant \delta f(z)-\|x-z\| \geqslant \delta f(z)-\|y-z\|-$ $\|x-y\|=\operatorname{lfs}_{\delta}(y)-\|x-y\|$.

Suppose that $y \notin \sigma_{x}$. By definition, $\operatorname{lfs}_{\delta}(y)=\delta f(z)-\|y-z\|$ for some point $z \in$ $\sigma_{y}$. If $z \notin \sigma_{x},\|x-z\| \geqslant g(z)$ and so $\operatorname{lfs}_{\delta}(y) \leqslant g(z)-\|y-z\| \leqslant\|x-z\|-\|y-z\| \leqslant$ $\|x-y\|<\operatorname{lfs}_{\delta}(x)+\|x-y\|$. If $z \in \sigma_{x}$, we have proved in the previous paragraph that $\operatorname{lfs}_{\delta}(x) \geqslant \operatorname{lfs}_{\delta}(z)-\|x-z\|$. So $\operatorname{lfs}_{\delta}(y)=\delta f(z)-\|y-z\| \leqslant \operatorname{lfs}_{\delta}(z)-\|y-z\| \leqslant$ $\operatorname{lfs}_{\delta}(x)+\|x-z\|-\|y-z\| \leqslant \operatorname{lfs}_{\delta}(x)+\|x-y\|$.

The next result shows that the properties in Lemma 2.1 hold for lfs ${ }_{\delta}$ as well.
Lemma 2.4 Lemma 2.1 holds with $f$ replaced by $\mathrm{lfs}_{\delta}$.
Proof Take a point $x$ on a 1- or 2-face $\sigma$. By definition, $\operatorname{lfs}_{\delta}(x)=\delta f(y)-\|x-y\|$ for some $y \in \sigma$. So lfs $\delta(x) \leqslant \delta m_{\sigma}(y)-\|x-y\| \leqslant m_{\sigma}(x)$. Then, standard results in $\varepsilon$-sampling imply that Lemma 2.1 (i)(a) and (ii) hold for lfs $\delta$. Take any $r<\operatorname{lfs}_{\delta}(x)$. Since lfs $\delta(x) \leqslant m_{\sigma}(x), B(x, r) \cap \operatorname{mani}(\sigma)$ is a closed ball of dimension $\operatorname{dim}(\sigma)[6$, 19]. It remains to show that $B(x, r) \cap \sigma$ is also a closed ball of dimension $\operatorname{dim}(\sigma)$.

If $\sigma$ is a 1 -face, the endpoints of $\sigma$ split $B(x, r) \cap \operatorname{mani}(\sigma)$ into at most three subcurves, one of which is $B(x, r) \cap \sigma$.

Suppose that $\sigma$ is a 2-face. If int $B(x, r)$ avoids bd $\sigma, B(x, r) \cap \sigma=B(x, r) \cap$ $\operatorname{mani}(\sigma)$, and we are done. Suppose that int $B(x, r)$ intersects bd $\sigma$. Then, lfs ${ }_{\delta}(x)=$ $\delta f(y)-\|x-y\|$ for some point $y \in \operatorname{bd} \sigma$ because if $x \in \operatorname{int} \sigma$ and $\operatorname{lfs}_{\delta}(x)=\delta f(x)$, $B(x, r)$ would avoid bd $\sigma$ as $f(x) \leqslant g(x)$. So $B(x, r) \subset B(y, \delta f(y))$. Let $E$ be the set of 1 -faces in bd $\sigma$ containing $y$. We have $|E|=1$ when $y$ is in the interior of a 1 -face and $|E|=2$ when $y$ is the common endpoint of two 1 -faces in bd $\sigma$. Since $f(y) \leqslant g(y)$ and $f(y) \leqslant m(y)$, we know that:
(1) $B(y, \delta f(y))$ avoids any 1 -face in $\operatorname{bd} \sigma$ that does not belong to $E$; so does $B(x, r)$.
(2) $B(y, \delta f(y))$ avoids the medial axis of $\operatorname{mani}(\tau)$ for each $\tau \in E$; so does $B(x, r)$.

By (2), it is known that $B(x, r) \cap \operatorname{mani}(\tau)$ is an open curve for each $\tau \in E$.
If $E$ contains only one 1 -face $\tau$, then $y \in$ int $\tau$. Since $f(y) \leqslant g(y), B(y, \delta f(y))$ avoids the endpoints of $\tau$. So does $B(x, r)$. Thus, $B(x, r) \cap \tau=B(x, r) \cap \operatorname{mani}(\tau)$, i.e., an open curve, and it splits $B(x, r) \cap \operatorname{mani}(\sigma)$ into two topological disks, one of which is $B(x, r) \cap \sigma$.

If $E$ contains two 1-faces $\tau_{1}$ and $\tau_{2}, y$ is a common endpoint of $\tau_{1}$ and $\tau_{2}$. Again, both $B(y, \delta f(y))$ and $B(x, r)$ avoid the other endpoints of $\tau_{1}$ and $\tau_{2}$. If $y \in B(x, r)$, $B(x, r) \cap \tau_{1}$ concatenates with $B(x, r) \cap \tau_{2}$ to form an open curve. This open curve splits $B(x, r) \cap \operatorname{mani}(\sigma)$ into two topological disks, one of which is $B(x, r) \cap \sigma$. If $y \notin B(x, r), B(x, r) \cap \tau_{i}=B(x, r) \cap \operatorname{mani}\left(\tau_{i}\right)$ for $i \in\{1,2\}$. These two open curves are disjoint, and they split $B(x, r) \cap \operatorname{mani}(\sigma)$ into three topological disks, one of which is $B(x, r) \cap \sigma$.

Notice that $\mathrm{lfs}_{\delta}$ is actually $\delta$-Lipschitz at points that are away from the element boundaries in $\mathcal{D}$. However, when a point $x$ is close to some element boundary, $\mathrm{lfs}_{\delta}(x)$ becomes 1-Lipschitz by construction. The parameterized propagation of the value of $f$ from boundaries matches well with our algorithmic strategy to protect the vertices and 1 -faces with balls. We will see that $\delta$ is related to the radii of these protecting balls.

### 2.2 A Computable Alternative

It would be ideal if we can compute $\operatorname{lfs}_{\delta}(x)$ for any point $x \in|\mathcal{D}|$. Doing so requires computing $m(x)$, which in turn requires computing the medial axis of smooth surfaces and curves. This is a challenging problem by itself. We face a greater problem because of the maximization over bd $\left|\mathcal{D}_{i}\right|$ used in defining lfs ${ }_{\delta}$.

We propose to compute a function $\mathrm{f}_{\omega}:\left|\mathcal{D}_{\leqslant 1}\right| \rightarrow \mathbb{R}$ for a parameter $\omega \in(0,1)$. The value $\mathrm{f}_{\omega}(x)$ enjoys several nice features of $\operatorname{lfs}_{\delta}(x)$, and it is good enough for our purpose. For example, we will see that if $\delta \leqslant \omega, \operatorname{lfs}_{\delta}(x) \leqslant \mathrm{f}_{\omega}(x)$ for the points $x \in\left|\mathcal{D}_{\leqslant 1}\right|$ that we are interested in. This makes $\mathrm{f}_{\omega}$ appropriate for defining the radii of protecting balls covering $\left|\mathcal{D}_{\leqslant 1}\right|$, i.e., points outside the protecting balls are at distances at least local feature sizes away from $\left|\mathcal{D}_{\leqslant 1}\right|$.

Let $x$ be a point in some 1 -face. First, for any 1 - or 2 -face $\sigma$ containing $x$, define $\sigma_{x, \omega}=\left\{y \in \operatorname{mani}(\sigma): \cos \left(\angle n_{\sigma}(x), n_{\sigma}(y)\right)=\cos \omega\right\}$. The distance between $x$ and $\sigma_{x, \omega}$ is the $\omega$-deviation radius of $x$ with respect to $\sigma$. We define $d_{\omega}(x)$ to be the minimum of the $\omega$-deviation radii of $x$ over all faces containing $x$. Second, we define $b(x)$ to be the largest value such that for any $r<b(x), B(x, r) \cap \operatorname{mani}(\sigma)$ is a closed ball for any 1- or 2-face $\sigma$ containing $x$.

Definition 2.3 For any point $x \in\left|\mathcal{D}_{\leqslant 1}\right|$, define $\mathrm{f}_{\omega}(x)=\min \left\{d_{\omega}(x), g(x), b(x)\right\}$.
The function $f_{\omega}$ satisfies the following properties.
Lemma 2.5 Let $\omega \in\left(0, \frac{\pi}{8}\right)$.
(i) For any point $x \in\left|\mathcal{D}_{1}\right|, \mathrm{f}_{\omega}(x) \in\left[\frac{\omega}{2} f(x), g(x)\right]$.
(ii) For any 1- or 2-face $\sigma$,
(a) for any points $x, y \in \operatorname{mani}(\sigma)$ such that $\|x-y\|<\mathrm{f}_{\omega}(x), \angle n_{\sigma}(x), n_{\sigma}(y)<$ $\omega$;
(b) for any point $x \in \sigma$ and for any $r<\mathrm{f}_{\omega}(x), B(x, r) \cap \operatorname{mani}(\sigma)$ and $B(x, r) \cap$ $\sigma$ are closed balls of dimension $\operatorname{dim}(\sigma)$.
(iii) For any 1-face $\sigma$ and for any points $x, y, z \in \operatorname{mani}(\sigma)$ such that $y, z \in B(x, r)$ for some $r<\mathrm{f}_{\omega}(x)$, one has $\angle n_{\sigma}(x), y z>\pi / 2-\omega$.
(iv) For any 2-face $\sigma$ and for any points $x, y, z \in \operatorname{mani}(\sigma)$ such that $y, z \in B(x, r)$ for some $r<\frac{1}{3} \mathrm{f}_{\omega}(x)$, one has $\angle n_{\sigma}(x), y z>\frac{\pi}{2}-\omega$.

Proof By the standard normal variation result, for any 1- or 2-face $\sigma$ and for any points $x, y \in \operatorname{mani}(\sigma)$, if $\|x-y\| \leqslant \frac{\omega}{2} m_{\sigma}(x), \angle n_{\sigma}(x), n_{\sigma}(y) \leqslant \frac{\omega / 2}{1-\omega / 2}$. By the definition of $d_{\omega}(x), \angle n_{\tau}(x), n_{\tau}(z)=\omega$ for some face $\tau$ containing $x$ and some point $z \in \operatorname{mani}(\tau)$ such that $\|x-z\|=d_{\omega}(x)$. Because $\omega<1, \frac{\omega / 2}{1-\omega / 2}<\omega$, which implies that $d_{\omega}(x)>\frac{\omega}{2} m_{\tau}(x)$. Therefore, $d_{\omega}(x)>\frac{\omega}{2} m(x) \geqslant \frac{\omega}{2} f(x)$. By definition, $g(x) \geqslant f(x)$. It follows from Lemma 2.1(i)(b) that $b(x) \geqslant f(x)$. Thus, $g(x) \geqslant$ $\min \left\{d_{\omega}(x), g(x), b(x)\right\}=\mathrm{f}_{\omega}(x) \geqslant \frac{\omega}{2} f(x)$. This proves (i). Since $\mathrm{f}_{\omega}(x) \leqslant d_{\omega}(x)$, (ii)(a) is enforced by construction. Since $r<\mathrm{f}_{\omega}(x) \leqslant b(x)$, for any 1- or 2-face $\sigma$ containing $x, B(x, r) \cap \operatorname{mani}(\sigma)$ is enforced to be a closed ball. Then, since $r<\mathrm{f}_{\omega}(x) \leqslant \omega g(x), B(x, r) \cap \sigma$ is also a closed ball by Lemma 1.1. This proves (ii)(b). Since $\omega<\pi / 8$ by assumption, the correctness of (iii) and (iv) follows from (ii) and Lemma 1.3.

By Definition 2.3, $\mathrm{f}_{\omega}(x)$ is obtained by computing $d_{\omega}(x), g(x)$, and $b(x)$. The computations of $g(x)$ and $b(x)$ are easily translated into solving systems of equations. So is the computation of $d_{\omega}(x)$, provided that for any 2 -face $\sigma$ containing $x$, the set $\sigma_{x, \omega}=\left\{y \in \operatorname{mani}(\sigma): \cos \left(\angle n_{\sigma}(x), n_{\sigma}(y)\right)=\cos \omega\right\}$ is a collection of disjoint smooth closed curves. When $\sigma_{x, \omega}$ is not a collection of disjoint smooth closed curves, $\cos \omega$ is a critical value of the function $y \mapsto \cos \left(\angle n_{\sigma}(x), n_{\sigma}(y)\right)$ by well-known results in Morse theory [25]. We call $\omega$ critical if $\cos \omega$ is a critical value. We first detect whether $\omega$ is critical by testing the solvability of a system of equations. If $\omega$ is critical, we perturb $\omega$ to a non-critical value $\bar{\omega}<\omega$ and compute $\mathrm{f}_{\bar{\omega}}(x)$ instead. Moreover, $\bar{\omega}$ can be made as close to $\omega$ as one wishes. We call $\bar{\omega}$ a non-critical value for $x$. The details of the perturbation of $\omega$ and the computations of $d_{\omega}(x), g(x)$, and $b(x)$ are given in Appendix B.

## 3 Protecting Vertices and Curves

Our algorithm starts with constructing protecting balls centered at judiciously chosen locations in $\left|\mathcal{D}_{\leqslant 1}\right|$. The radii of the protecting balls are controlled by $f_{\omega}$ (We may need to perturb $\omega$ if it happens to be critical). The value of $\mathrm{f}_{\omega}$ may fluctuate greatly as it is not 1-Lipschitz. So we enforce a Lipschitz-like property on the fly as we construct the balls. In the end each protecting ball is turned into an equivalent weighted point.

We choose $\lambda \leqslant 0.01$ and $\omega \leqslant 0.01$. First, we put a protecting ball $B_{u}$ centered at each vertex $u \in \mathcal{D}_{0}$ with radius $\left(B_{u}\right)=\lambda \mathrm{f}_{\omega_{u}}(u)$, where $\omega_{u}$ is a noncritical value for $u$ in the range $[0.99 \omega, \omega]$. Clearly, $\mathrm{f}_{\omega_{u}}(u) \leqslant \mathrm{f}_{\omega}(u)$. Let $\sigma$ be a 1-face. Let $u$ and $v$

Fig. 1 The balls
$B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right)$ and $B\left(x_{0}, r_{0 k}\right)$ are drawn with dashed circles. The bold circle denotes $B_{x_{k}}$

be the endpoints of $\sigma$. We will incrementally put a certain number of points in int $\sigma$ from $u$ to $v$. For notational convenience, we denote this number by $m$ although $m$ is unknown at the beginning.

Define $x_{1}=u$ and $r_{1}=\lambda \mathrm{f}_{\omega_{1}}(u)$, where $\omega_{1}=\omega_{u}$. We compute the intersection points $x_{2}=\sigma \cap \operatorname{bd} B_{u}$ and $x_{0}=\sigma \cap \operatorname{bd} B_{v}$. Define $r_{2}=\lambda \mathrm{f}_{\omega_{2}}\left(x_{2}\right)$ and $r_{0}=\lambda \mathrm{f}_{\omega_{0}}\left(x_{0}\right)$, where $\omega_{0}$ and $\omega_{2}$ are some noncritical values for $x_{0}$ and $x_{2}$, respectively, in the range $[0.99 \omega, \omega]$. The protecting ball at $x_{2}$ is $B_{x_{2}}=B\left(x_{2}, r_{2}\right)$. The protecting ball at $x_{0}$ will be constructed last. We march from $B_{x_{2}}$ toward $x_{0}$ to construct more protecting balls. For $k \geqslant 3$, we compute the two intersection points between $\sigma$ and the boundary of $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right)$. Among these two points let $x_{k}$ be the point such that $\angle x_{k-2} x_{k-1} x_{k}>$ $\pi / 2$. One can show that $x_{k}$ is well defined and $x_{k}$ lies between $x_{k-1}$ and $v$ along $\sigma$. Define

$$
r_{k}=\max \left\{\frac{1}{2}\left\|x_{k-1}-x_{k}\right\|, \min _{0 \leqslant j \leqslant k}\left\{\lambda \mathrm{f}_{\omega_{j}}\left(x_{j}\right)+\lambda\left\|x_{j}-x_{k}\right\|\right\}\right\},
$$

where $\omega_{j}$ is some noncritical value for $x_{j}$ in the range $[0.99 \omega, \omega]$ and

$$
r_{0 k}=\min _{0 \leqslant j \leqslant k}\left\{r_{j}+\lambda\left\|x_{j}-x_{0}\right\|\right\} .
$$

If $B\left(x_{k}, r_{k}\right) \cap B\left(x_{0}, r_{0 k}\right)=\emptyset$, the protecting ball at $x_{k}$ is

$$
B_{x_{k}}=B\left(x_{k}, r_{k}\right) .
$$

(Although we do not perform such a test for $B\left(x_{2}, r_{2}\right)$, we can define $r_{02}=$ $\min _{0 \leqslant j \leqslant 2}\left\{r_{j}+\lambda\left\|x_{j}-x_{0}\right\|\right\}$ and prove that $B\left(x_{2}, r_{2}\right) \cap B\left(x_{0}, r_{02}\right)=\emptyset$.

Figure 1 shows an example of the construction of $B_{x_{k}}$. We force $r_{k} \geqslant \frac{1}{2}\left\|x_{k-1}-x_{k}\right\|$ so that $B_{x_{k}}$ overlaps significantly with $B_{x_{k-1}}$.

We continue to march toward $x_{0}$ and construct protecting balls until the candidate ball $B\left(x_{m}, r_{m}\right)$ that we want to put down overlaps with $B\left(x_{0}, r_{0 m}\right)$. In this case, we reject $x_{m}$ and $B\left(x_{m}, r_{m}\right)$. We set the protecting ball at $x_{0}$ to be $B_{x_{0}}=B\left(x_{0}, \frac{4}{5} r_{0 m-1}\right)$. We use $\frac{4}{5} r_{0 m-1}$ as the radius of $B_{x_{0}}$ so as to keep some distance between $B_{x_{m-1}}$ and $B_{x_{0}}$ This will be useful in showing that nonconsecutive protecting balls are "far apart." On the other hand, radius ( $B_{x_{0}}$ ) cannot be too small so as to keep some distance between $B_{v}$ and the protecting ball to be placed to cover the gap between $B_{x_{m-1}}$ and $B_{x_{0}}$.

To cover the gap between $B_{x_{m-1}}$ and $B_{x_{0}}$, a convenient choice is a ball orthogonal to $B_{x_{m-1}}$ and $B_{x_{0}}$. The details are as follows. Compute the bisector plane of $B_{x_{m-1}}$ and $B_{x_{0}}$ with respect to the weighted distance [5] and then intersect it with $\sigma$. Select the intersection point $y_{m}$ that is within a distance of $4 r_{0}$ from $x_{0}$. We can show that $y_{m}$ is uniquely defined and $y_{m}$ lies between $x_{m-1}$ and $x_{0}$ along $\sigma$. The protecting ball $B_{y_{m}}$ is the ball centered at $y_{m}$ orthogonal to $B_{x_{m-1}}$ and $B_{x_{0}}$, i.e., radius $\left(B_{y_{m}}\right)^{2}=$
$\left\|x_{i}-y_{m}\right\|^{2}-\operatorname{radius}\left(B_{x_{i}}\right)^{2}$ for $i \in\{0, m-1\}$. Notice that radius $\left(B_{x_{0}}\right)$ may not be $r_{0}$, $y_{m}$ may not be $x_{m}$, and radius ( $B_{y_{m}}$ ) may not be $r_{m}$. Also, $y_{m}$ lies outside $B_{x_{m-1}}$ and $B_{x_{0}} ; x_{m-1}$ and $x_{0}$ lie outside $B_{y_{m}}$.

We turn each protecting ball $B_{p}$ into a weighted point $p$ with weight $w_{p}=$ radius $\left(B_{p}\right)^{2}$. Although our algorithm uses only the weighted vertices, we will refer to both ( $p, w_{p}$ ) and the protecting ball $B_{p}$ in the analysis. Two protecting balls are consecutive if their centers are adjacent along $\sigma$. Lemma 3.1 below summarizes the properties of the protecting balls. The proof involves some detailed calculations and are left in Appendix C.

Lemma 3.1 Let $\sigma$ be a 1-face. The construction of protecting balls for $\sigma$ terminates, and the following properties hold:
(i) Two consecutive protecting balls overlap.
(ii) For each weighted point $p$ on $\sigma, \operatorname{radius}\left(B_{p}\right) \in\left(\frac{\lambda \omega}{21} f(p), 5 \lambda g(p)\right)$.
(iii) Let $\tau$ be $\sigma$ or any 2-face incident to $\sigma$. Let $p$ be a weighted point on $\sigma$. For any $r \leqslant 20 \cdot \operatorname{radius}\left(B_{p}\right)$,
(a) for any point $z \in B(p, r) \cap \operatorname{mani}(\tau), \angle n_{\tau}(p), n_{\tau}(z)<2 \omega$;
(b) $B(p, r) \cap \operatorname{mani}(\tau)$ and $B(p, r) \cap \tau$ are closed balls of dimension $\operatorname{dim}(\tau)$.
(iv) For any two consecutive protecting balls $B_{p}$ and $B_{q}$,
(a) $q \notin \operatorname{int} B_{p}$,
(b) for any point $b$ on the circle $\operatorname{bd} B_{p} \cap \mathrm{bd} B_{q}, \angle p b q<170^{\circ}$,
(c) $B_{p} \cup B_{q}$ contains the subcurve $\sigma(p, q)$ of $\sigma$ between $p$ and $q$, and
(d) for any point $z \in \sigma(p, q), B_{p} \cup B_{q}$ contains the ball centered at $z$ with radius $\frac{\lambda \omega}{2500} f(z)$.
(v) For any nonconsecutive protecting balls $B_{p}$ and $B_{q}$, the minimum distance between $B_{p}$ and $B_{q}$ is at least $0.06 \cdot \min \left\{\operatorname{radius}\left(B_{p}\right)\right.$, radius $\left(B_{q}\right)$ \}. The points $p$ and $q$ are allowed to lie on different 1-faces.

## 4 Meshing a PSC

Our algorithm grows an admissible point set $S$ throughout the meshing process. We call a point set admissible if:

- The set contains all weighted points placed in $|\mathcal{D} \leqslant 1|$ during the protection phase.
- Other points in the set are unweighted, and they lie outside the protecting balls.

The point set $S$ is initialized to contain the weighted points on the 1 -faces. Then, we incrementally insert unweighted vertices in regions not covered by the protecting balls using the Delaunay refinement paradigm. In Sect. 4.1 we describe the subroutines used by our meshing algorithm. We present the meshing algorithm in Sect. 4.2. The following notation will be needed.

For each simplex $\eta \in \operatorname{Del} S, V_{\eta}$ denotes the Voronoi cell in Vor $S$ dual to $\eta$. For any 1- or 2-face $\sigma$ and for any simplex $\eta \in \operatorname{Del} S,\left.V_{\eta}\right|_{\sigma}$ denotes $V_{\eta} \cap \sigma$. We use Del $\left.S\right|_{\sigma}$ to denote the Delaunay subcomplex restricted to $\sigma$, i.e., the set of simplices $\eta \in \operatorname{Del} S$ such that $\left.V_{\eta}\right|_{\sigma} \neq \emptyset$. We extend the above definition to $\mathcal{D}_{i}$ for $0 \leqslant i \leqslant 2$ and $\mathcal{D}$ :

Fig. 2 It is dangerous to allow an edge between nonadjacent weighted points. If $p q$ belongs to $\left.\operatorname{Del} S\right|_{\tau}$ and $\left.\operatorname{Del} S\right|_{\sigma},\left.\operatorname{Del} S\right|_{\mathcal{D}}$ is pinched at $p q$

$$
\left.\operatorname{Del} S\right|_{\mathcal{D}_{i}}=\left.\bigcup_{\sigma \in \mathcal{D}_{i}} \operatorname{Del} S\right|_{\sigma},\left.\quad \operatorname{Del} S\right|_{\mathcal{D}}=\left.\bigcup_{\sigma \in \mathcal{D}} \operatorname{Del} S\right|_{\sigma}
$$

For any triangle $\left.t \in \operatorname{Del} S\right|_{\sigma}$, define $\operatorname{size}(t, \sigma)$ to be the maximum weighted distance between the vertices of $t$ and points in $\left.V_{t}\right|_{\sigma}$. For each point $p \in S \cap \sigma$, we use $\operatorname{star}(p, \sigma)$ to denote the set of edges and triangles in $\left.\operatorname{Del} S\right|_{\sigma}$ incident to $p$.

### 4.1 Subroutines

We describe the subroutines used by our algorithm. Two of them, Infringed and SurfaceNormal, require some preconditions, and we show later that the preconditions are satisfied throughout the algorithm.

Multiple Intersection Let $p$ be a point in $S \cap \sigma$ for some 2-face $\sigma$. If $V_{t}$ intersects $\sigma$ only once for any triangle $t \in \operatorname{star}(p, \sigma)$, Multilntersection $(p, \sigma)$ returns null; otherwise, Multilntersection $(p, \sigma)$ chooses a triangle $t \in \operatorname{star}(p, \sigma)$ such that $V_{t}$ intersects $\sigma$ more than once and returns the point $\left.x \in V_{t}\right|_{\sigma}$ that achieves $\operatorname{size}(t, \sigma)$.

Infringement Let $p$ be a point in $S \cap \sigma$ for some 2-face $\sigma$. We say that ( $p, \sigma$ ) is infringed if:

- $\left.p q \in \operatorname{Del} S\right|_{\sigma}$ for some point $q \notin \sigma$, or
- $p \in \operatorname{bd} \sigma$ and $\left.p q \in \operatorname{Del} S\right|_{\sigma}$ for some point $q \in \operatorname{bd} \sigma$ not adjacent to $p$. (See Fig. 2.)

We say that $p q$ certifies that $(p, \sigma)$ is infringed. Given $(p, \sigma)$, the subroutine $\operatorname{Infringed}(p, \sigma)$ requires a precondition that $V_{p q} \cap \mathrm{bd} \sigma=\emptyset$ for any edge $p q$ that certifies that $(p, \sigma)$ is infringed. Assuming this precondition, if $(p, \sigma)$ is not infringed, Infringed $(p, \sigma)$ returns null; otherwise, it returns a point in $V_{p q} \cap \sigma$ for some certifying edge $p q$. The implementation is given below.

Let $p q$ be any edge that certifies that $(p, \sigma)$ is infringed. $V_{p q} \cap \operatorname{mani}(\sigma)$ is a collection of smooth curves (open or closed). By the precondition, each curve in $V_{p q} \cap \operatorname{mani}(\sigma)$ is either contained in $V_{p q} \cap \sigma$ or disjoint from $V_{p q} \cap \sigma$. Notice that $V_{p q} \cap \sigma \neq \emptyset$ because $\left.p q \in \operatorname{Del} S\right|_{\sigma}$. We first solve for the intersections between $\operatorname{bd} V_{p q}$ and mani $(\sigma)$. If any intersection obtained belongs to $\sigma$, return it, and we are done. Otherwise, we need to check the closed curves in $V_{p q} \cap \operatorname{mani}(\sigma)$. Let $E(x)=0$ be the equation of mani $(\sigma)$. Choose two unit vectors $\vec{d}_{1}$ and $\vec{d}_{2}$ orthogonal and parallel to the plane of $V_{p q}$, respectively. Let us denote the standard inner product between two vectors $\vec{u}$ and $\vec{v}$ by $\langle\vec{u}, \vec{v}\rangle$. We solve the following system for $x: E(x)=0$, $\left\langle\nabla E(x) \times \vec{d}_{1}, \vec{d}_{2}\right\rangle=0$. The solutions are the critical points of curves in $V_{p q} \cap \operatorname{mani}(\sigma)$ in direction $\vec{d}_{2}$. Return any critical point that belongs to $\sigma$.

Surface Normal Variation Let $p$ be a point in $S \cap \sigma$ for some 2-face $\sigma$. Let $\phi_{s}$ be a constant chosen from $\left(4 \omega, \frac{\pi}{16}\right)$. Recall that $\sigma_{p, \phi_{s}}=\left\{x \in \operatorname{mani}(\sigma): \angle n_{\sigma}(p), n_{\sigma}(x)=\right.$ $\left.\phi_{s}\right\}$. The subroutine $\operatorname{Surface} \operatorname{Normal}\left(p, \sigma, \phi_{s}\right)$ requires a precondition that $\sigma_{p, \phi_{s}} \cap$ $V_{p} \cap \mathrm{bd} \sigma=\emptyset$.

Given $p, \sigma$, and $\phi_{s}$ that satisfy the precondition, if $\angle n_{\sigma}(p), n_{\sigma}(z)<\phi_{s}$ for any point $\left.z \in V_{p}\right|_{\sigma}$, $\operatorname{Surface} \operatorname{Normal}\left(p, \sigma, \phi_{s}\right)$ returns null; otherwise, it returns a point $\left.z \in V_{p}\right|_{\sigma}$ such that $\angle n_{\sigma}(p), n_{\sigma}(z)=\phi_{s}$. We describe the implementation of SurfaceNormal $\left(p, \sigma, \phi_{s}\right)$ below, which is reminiscent of the computation of $d_{\omega}(x)$ in setting $\mathrm{f}_{\omega}(x)$.

First, we can assume that $\phi_{s}$ is not a critical value for $p$, i.e., $\sigma_{p, \phi_{s}}$ is a collection of disjoint smooth closed curves. This can be enforced by perturbing $\phi_{s}$ as described in Appendix B. Let $E(x)=0$ be the equation of mani $(\sigma)$. Define $G(x)=\langle\nabla E(p), \nabla E(x)\rangle-\|\nabla E(p)\| \cdot\|\nabla E(x)\| \cdot \cos \phi_{s}$. The set $\sigma_{p, \phi_{s}}$ is described by the system $E(x)=0, G(x)=0$. We solve for the set of intersections between $\sigma_{p, \phi_{s}}$ and the support planes of $V_{p}$. If any intersection obtained belongs to $\left.V_{p}\right|_{\sigma}$, return it. If no intersection in $\left.V_{p}\right|_{\sigma}$ is obtained, the open curves in $\sigma_{p, \phi_{s}} \cap V_{p}$ are disjoint from $\left.V_{p}\right|_{\sigma}$ by the precondition. We still need to check the closed curves in $\sigma_{p, \phi_{s}}$ inside $V_{p}$. By the precondition, any closed curve in $\sigma_{p, \phi_{s}}$ inside $V_{p}$ is either contained in $\left.V_{p}\right|_{\sigma}$ or disjoint from $\left.V_{p}\right|_{\sigma}$. We solve the system $E(x)=0, G(x)=0$, $\langle\nabla G(x) \times \nabla E(x),(p-x)\rangle=0$. The solutions are the tangential contact points with $\sigma_{p, \phi_{s}}$ and balls centered at $p$. If any tangential contact point belongs to $\left.V_{p}\right|_{\sigma}$, return it. If no contact point is found in $\left.V_{p}\right|_{\sigma}, \sigma_{p, \phi_{s}}$ avoids $\left.V_{p}\right|_{\sigma}$, and we return null.

Curve Normal Variation Let $p$ be a point in $S \cap \sigma$ for some 2-face $\sigma$. Let $\phi_{c}$ be a constant chosen from $\left(\phi_{s}+8 \omega, \frac{\pi}{16}+8 \omega\right)$. $\operatorname{CurveNormal}\left(p, \sigma, \phi_{c}\right)$ returns a point $\left.y \in V_{e}\right|_{\sigma}$ for some edge $e \in \operatorname{star}(p, \sigma)$ such that $\angle \vec{d}_{1}, \vec{d}_{2}=\phi_{c}$, where $\vec{d}_{1}$ and $\vec{d}_{2}$ are the projections of $n_{\sigma}(p)$ and $n_{\sigma}(y)$ onto the plane of $V_{e}$, respectively. CurveNormal $\left(p, \sigma, \phi_{c}\right)$ returns null if such a point does not exist.

The implementation works as follows. Let $E(x)=0$ be the equation of mani $(\sigma)$. For each edge $e \in \operatorname{star}(p, \sigma)$, let $q_{e}$ denote a point on the support plane of $V_{e}$; let $n_{e}$ denote a unit vector orthogonal to the support plane of $V_{e}$; and define the function $G_{e}(x)=\nabla E(x)-\left\langle\nabla E(x), n_{e}\right\rangle \cdot n_{e}$. Notice that $G_{e}(x)$ is the projection of the vector $\nabla E(x)$ onto a plane orthogonal to $n_{e}$. We solve the system $E(x)=0,\left\langle\left(x-q_{e}\right), n_{e}\right\rangle=$ $0,\left\langle G_{e}(x), G_{e}(p)\right\rangle=\left\|G_{e}(x)\right\| \cdot\left\|G_{e}(p)\right\| \cdot \cos \phi_{c}$. If any solution obtained belongs to $\left.V_{e}\right|_{\sigma}$, return it. Return null if no solution can be returned for any edge in $\operatorname{star}(p, \sigma)$.

Disk Neighborhood Let $p$ be a point in $S \cap \sigma$ for some 2-face $\sigma$. $\operatorname{NoDisk}(p, \sigma)$ returns null if the union of triangles in $\operatorname{star}(p, \sigma)$ is a topological disk. Otherwise, $\operatorname{NoDisk}(p, \sigma)$ chooses the triangle $t \in \operatorname{star}(p, \sigma)$ with maximum $\operatorname{size}(t, \sigma)$ and returns the point $\left.x \in V_{t}\right|_{\sigma}$ that achieves $\operatorname{size}(t, \sigma)$. Notice that when $p \in \operatorname{bd} \sigma, p$ belongs to the boundary of the union of triangles in $\operatorname{star}(p, \sigma)$.

### 4.2 Algorithm

The following pseudocodes summarize our algorithm. The procedure FindViolation is responsible for the incremental point insertion. The meshing of the input PSC $\mathcal{D}$
is initiated by calling $\operatorname{MeshPSC}(\mathcal{D})$. The parameters $\lambda$ and $\omega$ used in protecting the input vertices and 1 -faces are picked from $(0,0.01]$. The angle parameters $\phi_{s}$ and $\phi_{c}$ are picked from $\left(4 \omega, \frac{\pi}{16}\right)$ and $\left(\phi_{s}+4 \omega, \frac{\pi}{16}+4 \omega\right)$, respectively. A noteworthy feature of our algorithm is that FindViolation never inserts a point inside the protecting balls. This eliminates the check for point insertions inside the protecting balls as well as the exception handler for such events.

## FindViolation $(p, \sigma)$

1. Call Multilntersection $(p, \sigma)$, Infringed $(p, \sigma)$, SurfaceNormal $\left(p, \sigma, \phi_{s}\right)$, CurveNormal $\left(p, \sigma, \phi_{c}\right)$ and $\operatorname{NoDisk}(p, \sigma)$ in this order. If a point $x$ is returned in some call, stop and return $x$.
2. Return null.

## MeshPSC( $\mathcal{D}$ )

1. Protect the vertices and 1-faces in $\mathcal{D}$ with weighted points. Insert a point in each 2 -face in $\mathcal{D}$ outside the protecting balls. Let $S$ be the resulting admissible point set.
2. For every $(p, \sigma)$ where $\sigma$ is a 2 -face and $p \in S \cap \sigma$,
(a) Compute $v:=$ FindViolation $(p, \sigma)$.
(b) If $v$ is non-null, insert $v$ into $S$ and update $\operatorname{Del} S$ and Vor $S$.
3. If $S$ has grown in the last execution of Step 2, repeat Step 2.
4. Return $\left.\operatorname{Del} S\right|_{\mathcal{D}}$.

Step 1 of MeshPSC requires further explanation because a point has to be inserted in each 2-face outside the protecting balls. Let $\sigma$ be a 2 -face. We arbitrarily pick two consecutive protecting balls $B_{p}$ and $B_{q}$, where $p$ and $q$ belong to bd $\sigma$. Lemma 5.3 in Sect. 5.1 implies the following:

- $B_{p}$ and $B_{q}$ induce a Voronoi facet $V_{p q}$ in Vor $S$.
- $V_{p q}$ intersects the subcurve $\sigma(p, q)$ of bd $\sigma$ between $p$ and $q$ exactly once and does not intersect bd $\sigma$ elsewhere.

It follows that we can trace a curve in $V_{p q} \cap \sigma$ starting from the intersection point between $V_{p q}$ and $\sigma(p, q)$. The tracing of this intersection curve either ends at a Voronoi edge in the boundary of $V_{p q}$ or at a tangential contact point between $\sigma$ and the interior of $V_{p q}$. We claim that any intersection point between the boundary of $V_{p q}$ and $\sigma$ and any tangential contact point between $V_{p q}$ and $\sigma$ is a point in $\sigma$ outside all protecting balls.

By our claim, a point in $\sigma$ outside all protecting balls can be computed as follows. First, compute the intersection points between the edges of $V_{p q}$ and $\sigma$. If an intersection point is found, return it, and we are done. Otherwise, let $H(x)=0$ be the equation of the support plane of $V_{p q}$, and we compute the tangential contact points between this plane and mani $(\sigma)$ by solving the system $E(x)=0, H(x)=0$, $\nabla H(x) \times \nabla E(x)=0$. Among the contact points obtained, return one that lies on $V_{p q}$ and $\sigma$.

We prove the correctness of our claim. Let $x$ be an intersection point between some edge of $V_{p q}$ and $\sigma$. The Voronoi edge containing $x$ is induced by $B_{p}, B_{q}$ and a third protecting ball $B_{s}$. Observe that $B_{p}$ and $B_{s}$ are nonconsecutive or $B_{q}$
and $B_{s}$ are nonconsecutive. So Lemma 3.1(v) implies that the weighted distance from $x$ to $B_{p}, B_{q}$, and $B_{s}$ is positive. Notice that $B_{p}, B_{q}$, and $B_{s}$ are the protecting balls with minimum weighted distance to $x$. Hence, $x$ lies outside all protecting balls. Let $x$ be a tangential contact point between $V_{p q}$ and $\sigma$. Without loss of generality, assume that radius $\left(B_{p}\right) \geqslant \operatorname{radius}\left(B_{q}\right)$. Because $B_{p}$ and $B_{q}$ overlap, $B_{q} \subseteq B\left(p, \frac{1}{3} r\right)$ where $r=9$ radius $\left(B_{p}\right)$. It follows from Lemma 3.1(iii) and Lemma 1.3(ii) that $\angle n_{\sigma}(p), p q>\pi / 2-2 \omega$. Since $x$ is a tangential contact point between $V_{p q}$ and $\sigma, n_{\sigma}(x)$ is parallel to $p q$ (i.e., orthogonal to $V_{p q}$ ), which implies that $\angle n_{\sigma}(p), n_{\sigma}(x)>\pi / 2-2 \omega$. Therefore, by Lemma 3.1(iii)(a), $x$ lies outside $B(p, r)$, which contains both $B_{p}$ and $B_{q}$. Hence, the weighted distance from $x$ to $B_{p}$ and $B_{q}$ is positive. Notice that $B_{p}$ and $B_{q}$ are the protecting balls with minimum weighted distance to $x$. This implies that $x$ is outside all protecting balls.

## 5 Analysis of the Meshing Algorithm

We will establish several facts about MeshPSC:

- The algorithm conforms to the 1 -faces.
- The preconditions of Infringed and SurfaceNormal are always satisfied.
- The algorithm maintains the admissibility of the point set $S$.
- The algorithm terminates.
- The extended TBP holds for $\mathcal{D}$ at the termination of the algorithm.

The conformity, preconditions of Infringed and SurfaceNormal, and the maintenance of admissibility is proved in Sect. 5.1. The termination of MeshPSC is proved in Sects. 5.2 and 5.3. The extended TBP is shown to hold in Sect. 5.4.

Throughout this section, $\varepsilon$ denotes a number picked from ( $0, \lambda \omega / 2500$ ), and $\mathrm{lfs}_{\varepsilon}^{*}$ denotes $\min \left\{\operatorname{lfs}_{\varepsilon}(x): x \in|\mathcal{D}|\right\}$. For each point $p$ in an admissible point set, define the range of $p$ as range $(p)=\operatorname{radius}\left(B_{p}\right)$ if $p$ is weighted and $\operatorname{range}(p)=\operatorname{lfs}_{\varepsilon}(p)$ otherwise. The orthoradius of a triangle $t \in \operatorname{Del} S$ is the radius of the smallest ball that has zero weighted distance to the vertices (possibly weighted) of $t$. We use ortho $(t)$ to denote the orthoradius of $t$. Note that if all vertices of $t$ are unweighted, ortho $(t)$ is just the circumradius of $t$.

The next lemma shows that $\operatorname{lfs}_{\varepsilon}(p)=\varepsilon f(p)$ for any point $p$ in an admissible point set. Moreover, our choice of $\varepsilon$ makes the protecting ball radii bounded from below by the local feature sizes at the ball centers.

Lemma 5.1 For any point $p$ in an admissible point set, $\operatorname{lfs}_{\varepsilon}(p)=\varepsilon f(p)$ and if $p$ is weighted, $\operatorname{range}(p)=\operatorname{radius}\left(B_{p}\right)>\operatorname{lfs}_{\varepsilon}(p)$.

Proof If $p \in \mathcal{D}_{0}, \operatorname{lfs}_{\varepsilon}(p)=\varepsilon f(p)$ by definition and radius $\left(B_{p}\right)=\lambda \mathrm{f}_{\omega_{p}}(p) \geqslant$ $\frac{\lambda \omega_{p}}{2} f(p)$ by Lemma $2.5(\mathrm{i})$. As $\omega_{p} \geqslant 0.99 \omega$ by our choice, we get $\operatorname{radius}\left(B_{p}\right) \geqslant$ $\frac{99}{200} \lambda \omega f(p)>\varepsilon f(p)=\operatorname{lfs}_{\varepsilon}(p)$. Suppose that $p \in \operatorname{int} \sigma$ for some 1-face $\sigma$. For any endpoint $q$ of $\sigma, q \in \mathcal{D}_{0}$, and we have just shown that $\operatorname{radius}\left(B_{q}\right)>\operatorname{lfs}_{\varepsilon}(q)=\varepsilon f(q)$. By Lemma 3.1(iv)(a) and (v), $p \notin \operatorname{int} B_{q}$ and so $\varepsilon f(q)-\|p-q\|<\operatorname{radius}\left(B_{q}\right)-$ $\|p-q\| \leqslant 0$. Then, it follows from the definition of $\operatorname{lfs}_{\varepsilon}$ that $\operatorname{lfs}_{\varepsilon}(p)=\varepsilon f(p)$. By

Lemma 3.1(ii), radius $\left(B_{p}\right)>\frac{\lambda \omega}{21} f(p)>\varepsilon f(p)$. Suppose that $p \in \operatorname{int} \sigma$ for some 2-face $\sigma$. Then, $p$ is unweighted. By Lemma 3.1(iv)(d), for any point $q \in \operatorname{bd} \sigma$, $B(q, \varepsilon f(q))$ is contained in the union of protecting balls whose centers belong to bd $\sigma$. Thus, $\varepsilon f(q)-\|p-q\| \leqslant 0$ because $p$ lies outside the protecting balls. Thus, the definition of $\operatorname{lfs}_{\varepsilon}$ implies that $\operatorname{lfs}_{\varepsilon}(p)=\varepsilon f(p)$.

The next lemma gives some topological and geometric properties of the neighborhood of a point $p$ in $S$.

Lemma 5.2 Let $p$ be a point in $S \cap \sigma$ for some admissible point set $S$ and for some 1- or 2-face $\sigma$.
(i) For any point $y \in B(p, 20 \operatorname{range}(p)) \cap \operatorname{mani}(\sigma), \angle n_{\sigma}(p), n_{\sigma}(y)<2 \omega$.
(ii) For any $r \leqslant 20 \operatorname{range}(p), B(p, r) \cap \operatorname{mani}(\sigma)$ and $B(p, r) \cap \sigma$ are topological balls of dimension $\operatorname{dim}(\sigma)$.
(iii) For any two points $y, z \in B(p, 6 \operatorname{range}(p)) \cap \operatorname{mani}(\sigma), \angle n_{\sigma}(p), y z>\pi / 2-2 \omega$.

Proof If $p$ is weighted, (i) follows from Lemma 3.1(iii)(a), (ii) follows from Lemma 3.1(iii)(b), and (iii) follows from Lemma 3.1(iii) and Lemma 1.3. Suppose that $p$ is unweighted. By Lemma 5.1, $\operatorname{range}(p)=\operatorname{lfs}_{\varepsilon}(p)=\varepsilon f(p)$. Then, (i) and (ii) follow from Lemma 2.1, and (iii) is obtained by applying Lemma 1.3.

### 5.1 Conformity, Preconditions, and Admissibility

Lemma 5.3 below states that the edges between adjacent weighted points are always restricted weighted Delaunay.

Lemma 5.3 Let $S$ be an admissible point set. Let $p$ and $q$ be two adjacent weighted points on some 1-face $\sigma$. Let $\sigma(p, q)$ denote the subcurve between $p$ and $q . V_{p q}$ is the only Voronoi facet in $\operatorname{Vor} S$ that intersects $\sigma(p, q)$ and $V_{p q}$ intersects $\sigma(p, q)$ exactly once.

Proof Let $H_{p q}$ be the bisector of $B_{p}$ and $B_{q}$ with respect to the weighted distance. By Lemma 3.1(iv)(a), $p \notin \operatorname{int} B_{q}$ and $q \notin \operatorname{int} B_{p}$. So $H_{p q}$ lies between $p$ and $q$, which means that $V_{p q}$ can potentially intersect $\sigma(p, q)$. We prove that this definitely happens by showing that no other Voronoi facet can intersect $\sigma(p, q)$. Pick an arbitrary point $z \in \sigma(p, q)$. Since $\sigma(p, q) \subset B_{p} \cup B_{q}$ by Lemma 3.1(iv)(c), the weighted distance of $z$ from $B_{p}$ or $B_{q}$ is negative.

For any unweighted point $s \in S$, since $s \notin B_{p} \cup B_{q},\|s-z\|>0$. This implies that $z$ does not belong to any Voronoi facet partly defined by $s$. Take any weighted point $s \in S$ other than $p$ and $q$. Assume without loss of generality that $z \in B_{p}$. If $s$ is not adjacent to $p, B_{p} \cap B_{s}=\emptyset$ by Lemma 3.1(v), implying that $z \notin B_{s}$. Suppose that $s$ is adjacent to $p$. Since $B_{s} \cap \sigma$ is an open curve by Lemma 3.1(iii)(b), $z \notin \operatorname{int} B_{s}$; otherwise, $p$ would also belong to int $B_{s}$, which is forbidden by Lemma 3.1(iv)(a). We conclude that the weighted distance of $z$ from $B_{s}$ is nonnegative. Thus, $z$ does not lie in any Voronoi facet partly defined by $s$.

Hence, $V_{p q}$ is the only Voronoi facet in Vor $S$ that intersects $\sigma(p, q)$. Without loss of generality, assume that radius $\left(B_{p}\right) \geqslant \operatorname{radius}\left(B_{q}\right)$. So $q \in B(p, 2 \operatorname{range}(p))$. We apply Lemma 5.2(iii) to $B(p, 2 \operatorname{range}(p)) \cap \sigma$. We conclude that $\angle n_{\sigma}(p), p q>$ $\pi / 2-2 \omega$ and for any points $y, z \in B(p, 2 \operatorname{range}(p)) \cap \sigma, \angle n_{\sigma}(p), y z>\pi / 2-2 \omega$. This implies that $\angle p q, y z<4 \omega$. By Lemma 5.2(ii), $B(p, 2 \operatorname{range}(p)) \cap \sigma$ is an open curve, implying that $\sigma(p, q) \subset B(p, 2$ range $(p)) \cap \sigma$. If $\sigma(p, q)$ intersects $V_{p q}$ at two points $y$ and $z$, then $\angle p q, y z=\pi / 2$, an impossibility.

The next lemma shows that the preconditions of Infringed and SurfaceNormal are always satisfied.

Lemma 5.4 The preconditions of Infringed and SurfaceNormal are satisfied when $S$ is an admissible point set.

Proof Consider the call Infringed $(p, \sigma)$. Let $p q$ be any edge that certifies that $(p, \sigma)$ is infringed. By Lemma 5.3, $V_{p q} \cap \operatorname{bd} \sigma=\emptyset$ because either $q \notin \sigma$ or $p \in \operatorname{bd} \sigma$ but $q$ is not an adjacent weighted point in $\operatorname{bd} \sigma$.

Consider the call SurfaceNormal $\left(p, \sigma, \phi_{s}\right)$. If $p \in \operatorname{int} \sigma$, by Lemma 5.3, $V_{p} \cap \mathrm{bd} \sigma$ is empty. So is $\sigma_{p, \phi_{s}} \cap V_{p} \cap \operatorname{bd} \sigma$. Suppose that $p \in \operatorname{bd} \sigma$, i.e., $p$ is weighted. Let $q$ be a weighted point in bd $\sigma$ adjacent to $p$. Let $B(a$, range $(a))$ denote the larger ball among $B_{p}$ and $B_{q}$. It follows that $p, q \in B(a, 2$ range $(a))$. By Lemma 5.2(ii), $B(a, 2$ range $(a)) \cap \mathrm{bd} \sigma$ contains the subcurve $\xi$ in $\operatorname{bd} \sigma$ between $p$ and $q$. By Lemma 5.2(i), for any point $y \in \xi, \angle n_{\sigma}(p), n_{\sigma}(y) \leqslant \angle n_{\sigma}(p), n_{\sigma}(a)+$ $\angle n_{\sigma}(y), n_{\sigma}(a)<4 \omega$. Let $s$ be the other weighted point in bd $\sigma$ adjacent to $p$. Let $\xi^{\prime}$ be the subcurve in $\operatorname{bd} \sigma$ between $p$ and $s$. We can similarly show that $\angle n_{\sigma}(p), n_{\sigma}(z)<4 \omega$ for any point $z \in \xi^{\prime}$. By Lemma 5.3, $V_{p} \cap$ bd $\sigma$ contains only portions of $\xi$ and $\xi^{\prime}$. This implies that $\sigma_{p, \phi_{s}} \cap V_{p} \cap \mathrm{bd} \sigma=\emptyset$ as $\phi_{s}>4 \omega$.

The next result shows that MeshPSC maintains the admissibility of $S$ throughout its execution. The proof depends on the usage of weighted Delaunay triangulation.

Lemma 5.5 MeshPSC never attempts to insert a point in any protecting ball. Hence, the point set $S$ is admissible throughout the execution of MeshPSC.

Proof Each point inserted by Multilntersection and NoDisk lies in the intersection of some Voronoi edge and $|\mathcal{D}|$. Since no three protecting balls intersect by Lemma 3.1(v), all points on a Voronoi edge have positive distance from all vertices, weighted or not. This means that no Voronoi edge intersects a protecting ball. Therefore, the points inserted by Multilntersection and NoDisk must lie outside all protecting balls.

Assume to the contrary that some call $\operatorname{Surface} \operatorname{Normal}\left(p, \sigma, \phi_{s}\right)$ returns a point $x$ that lies inside some protecting ball. So the weighted distance between $x$ and some weighted point is negative. The weighted distance between $x$ and $p$ must also be negative because $\left.x \in V_{p}\right|_{\sigma}$. It follows that $p$ is weighted and $x \in B_{p}$. Then, by Lemma 5.2(i), $\angle n_{\sigma}(p), n_{\sigma}(x)<2 \omega<\phi_{s}$. This is a contradiction because $\angle n_{\sigma}(p), n_{\sigma}(x)=\phi_{s}$ for $x$ to be returned by $\operatorname{SurfaceNormal}\left(p, \sigma, \phi_{s}\right)$.

Consider a call $\operatorname{Infringed}(p, \sigma)$ that returns a point $x \in V_{p q} \cap \sigma$ for some edge $p q \in \operatorname{star}(p, \sigma)$. Assume to the contrary that $x$ lies inside some protecting ball. It follows as in the previous paragraph that $p$ and $q$ are weighted and $x \in B_{p} \cap B_{q}$. In order to trigger Infringed to return a point, $B_{p}$ and $B_{q}$ must be nonconsecutive, but then $B_{p} \cap B_{q}=\emptyset$ by Lemma 3.1(v), contradicting the fact that $x \in B_{p} \cap B_{q}$.

Consider a call CurveNormal $\left(p, \sigma, \phi_{c}\right)$ that returns a point $x \in V_{p q} \cap \sigma$ for some edge $p q \in \operatorname{star}(p, \sigma)$. Assume to the contrary that $x$ lies inside some protecting ball. It follows as before that $p$ and $q$ must be weighted and consecutive and $x \in B_{p} \cap B_{q}$. Since $x \in B_{p}$, by Lemma 5.2(i), $\angle n_{\sigma}(p), n_{\sigma}(x)<2 \omega$. Let $B(a$, range $(a))$ denote the larger of $B_{p}$ and $B_{q}$. So $p, q \in B(a, 2$ range $(a))$. Then, Lemma 5.2(i) and (iii) imply that $\angle n_{\sigma}(p), p q \geqslant \angle n_{\sigma}(a), p q-\angle n_{\sigma}(a), n_{\sigma}(p)>\pi / 2-4 \omega$. It follows that $\angle n_{\sigma}(p), V_{p q}<4 \omega$. Let $\vec{d}_{1}$ and $\vec{d}_{2}$ denote the projections of $n_{\sigma}(p)$ and $n_{\sigma}(x)$ onto the plane of $V_{p q}$. We have $\angle \vec{d}_{1}, \vec{d}_{2} \leqslant \angle n_{\sigma}(p), n_{\sigma}(x)+\angle n_{\sigma}(p), V_{p q}+\angle n_{\sigma}(x), V_{p q} \leqslant$ $2 \cdot \angle n_{\sigma}(p), V_{p q}+2 \cdot \angle n_{\sigma}(p), n_{\sigma}(x)<12 \omega$. However, in order that CurveNormal returns $x$, we have $\angle \vec{d}_{1}, \vec{d}_{2}=\phi_{c}>\phi_{s}+8 \omega>12 \omega$, a contradiction.

### 5.2 Distance Lower Bounds

MeshPSC grows the point set $S$ incrementally, while maintaining its admissibility by Lemma 5.5. Recall that $\varepsilon$ is a number picked from $(0, \lambda \omega / 2500)$ and $\mathrm{lfs}_{\varepsilon}^{*}$ denotes $\min \left\{\operatorname{lfs}_{\varepsilon}(x): x \in|\mathcal{D}|\right\}$. We show that MeshPSC maintains inductively a lower bound of $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ on the distances among the points in $S$. This will allow us to apply the standard packing argument to claim that MeshPSC terminates.

### 5.2.1 Technical Results

We first prove several technical results. The next result states that if the distances among the points in $S$ are $\Omega\left(\right.$ lfs $\left._{\varepsilon}^{*}\right)$ and the orthoradius of a triangle $t$ is small with respect to $\mathrm{lfs}_{\varepsilon}^{*}$, the largest angle of $t$ is bounded.

Lemma 5.6 Let $S$ be an admissible point set. Assume that $\|a-b\| \geqslant 0.03$ lfs* $_{\varepsilon}^{*}$ for any $a, b \in S$. Let $t$ be a triangle in $\left.\operatorname{Del} S\right|_{\sigma}$ for some 2-face $\sigma$. If ortho $(t) \leqslant 0.03 \mathrm{lfs}_{\varepsilon}^{*}$, the largest angle of $t$ is less than $170^{\circ}$.

Proof Let $p, q$, and $s$ denote the vertices of $t$. Since ortho $(t) \leqslant 0.03$ lfs $_{\varepsilon}^{*}$, by Lemma 3.1(v), $t$ has at most two weighted vertices, and they must be adjacent along some 1 -face. Let $\angle p s q$ be the largest angle in $t$. Assume that $\angle p s q>\pi / 2$; otherwise, we are done.

Suppose that $s$ is weighted. So $p$ or $q$ is unweighted, say $p$. Let $H_{p s}$ be the bisector plane of $p$ and $B_{s}$. Since $p$ lies outside $B_{s}, H_{p s}$ lies between $p$ and $s$ and $H_{p s}$ is further from $s$ than $p$. This implies that the distance between $p$ and the orthocenter of $t$ is at least $\frac{1}{2}\|p-s\| \tan (\angle p s q-\pi / 2)$. Thus, $0.03 \mathrm{lfs}_{\varepsilon}^{*} \geqslant$ ortho $(t) \geqslant \frac{1}{2}\|p-s\| \tan (\angle p s q-\pi / 2) \geqslant 0.015$ lfs $_{\varepsilon}^{*} \tan (\angle p s q-\pi / 2)$, which implies that $\angle p s q \leqslant \pi / 2+\arctan (2)<170^{\circ}$.

Suppose that $s$ is unweighted. If both $p$ and $q$ are weighted (i.e., $p$ and $q$ are adjacent), $\angle p s q$ is maximized when $s$ lies on the circle bd $B_{q} \cap$ bd $B_{q}$. By

Lemma 3.1(iv)(b), $\angle p s q<170^{\circ}$ in this case. If $p$ or $q$ is unweighted, say $p$, we can repeat the argument in the previous paragraph to show that $\angle p s q<170^{\circ}$.

Under conditions similar to those in Lemma 5.6, the next result states that $V_{t}$ makes an $O(\omega)$ angle with the surface normals at the vertices of $t$.

Lemma 5.7 Let $S$ be an admissible point set. Assume that $\|a-b\| \geqslant 0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. Let $t$ be a triangle in $\left.\operatorname{Del} S\right|_{\sigma}$ for some 2-face $\sigma$. If ortho $(t) \leqslant 0.03 \mathrm{lfs}_{\varepsilon}^{*}$, $\angle n_{\sigma}(x), V_{t}<26 \omega$ for any vertex $x$ of $t$.

Proof Let $p, q$, and $s$ be the vertices of $t$. Let $\angle p s q$ be the largest angle of $t$. Lemma 5.6 implies that $60^{\circ} \leqslant \angle p s q<170^{\circ}$. Let $C$ be the double cone whose axis is the support line of $n_{\sigma}(s)$ and whose angular aperture is $\pi-4 \omega$.

We use $\alpha$ to denote $\angle n_{\sigma}(s), V_{t}$. We first show that $\alpha<24 \omega$. Assume that $\alpha>2 \omega$; otherwise, we are done. Let $H$ denote the support plane of pqs. Since $\alpha>2 \omega, H \cap C$ is a double wedge. Because range $(s) \geqslant \operatorname{lfs}_{\varepsilon}^{*}$ by Lemma 5.1 and ortho $(t) \leqslant 0.03 \mathrm{lfs}_{\varepsilon}^{*}$, we have $t \subset B(s, r)$, where $r=\operatorname{range}(s)+0.06$ lfs $_{\varepsilon}^{*}<2 \operatorname{range}(s)$. By Lemma 5.2(iii), $B(s, r) \cap \sigma$ intersects the double cone $C$ only at $s$. It follows that $p$ and $q$ do not belong to $H \cap C$. By elementary trigonometry, the angular aperture $\theta$ of $H \cap C$ satisfies the equation:

$$
\tan \frac{\theta}{2}=\frac{\sqrt{\sin (\alpha-2 \omega) \sin (\alpha+2 \omega)}}{\sin (2 \omega)}
$$

If $\alpha \geqslant 24 \omega$, the above equation yields $\theta>170^{\circ}$. So the angular aperture of the open double wedge $H \backslash C$ is less than $10^{\circ}$. Since $\angle p s q \geqslant 60^{\circ}, p$ and $q$ do not lie in the same wedge of $H \backslash C$. It follows that $\angle p s q$ is greater than the angular aperture of $H \cap C$ (i.e., $>170^{\circ}$ ). But this is impossible as $\angle p s q<170^{\circ}$. Hence, $\alpha<24 \omega$.

Since $t \subset B(s, r)$, by Lemma 5.2(i), for any vertex $x$ of $t, \angle n_{\sigma}(x), V_{t} \leqslant$ $\angle n_{\sigma}(s), V_{t}+\angle n_{\sigma}(s), n_{\sigma}(x)<\alpha+2 \omega<26 \omega$.

Lemma 5.8 Let $S$ be an admissible point set. Let $x$ be a point in $\left.V_{p}\right|_{\sigma}$ for some 2face $\sigma$. Let $D$ be the minimum distance between $x$ and the points in $S$. Let $W$ be the minimum weighted distance between $x$ and the points in $S$. If $D$ or $W$ is less than $\mathrm{lfs}_{\varepsilon}^{*}$, then $\|p-x\|<\sqrt{2} \operatorname{range}(p)$.

Proof We have $W<\operatorname{lfs}_{\varepsilon}^{*}$ if $D$ or $W$ is less than lfs $\varepsilon_{\varepsilon}^{*}$. If $p$ is unweighted, $\|p-x\|<$ $\operatorname{lfs}_{\varepsilon}^{*} \leqslant \operatorname{lfs}_{\varepsilon}(p)=\operatorname{range}(p)$. If $p$ is weighted, we have $\|p-x\|^{2}-\operatorname{radius}\left(B_{p}\right)^{2}<$ $\left(\text { lfs }_{\varepsilon}^{*}\right)^{2}$ because $x \in V_{p}$. Then, Lemma 5.1 implies that $\|p-x\|<\left(\operatorname{radius}\left(B_{p}\right)^{2}+\right.$ $\left.\left(\text { lfs }_{\varepsilon}^{*}\right)^{2}\right)^{1 / 2}<\sqrt{2} \operatorname{radius}\left(B_{p}\right)=\sqrt{2} \operatorname{range}(p)$.

Lemma 5.9 Let $S$ be an admissible point set. Let $\sigma$ be a 2-face. Let pq be an edge in $\operatorname{star}(p, \sigma)$ for some point $p \in S \cap \sigma$. If there is a point $\left.x \in V_{p q}\right|_{\sigma}$ such that the minimum distance between $x$ and the points in $S$ is less than $\mathrm{lfs}_{\varepsilon}^{*}$, then $\angle n_{\sigma}(p), V_{p q}<$ $4 \omega$.

Proof By Lemma 5.8, $\|p-x\|<\sqrt{2}$ range $(p)$ and $\|q-x\|<\sqrt{2} \operatorname{range}(q)$. So $\|p-q\|<2 \sqrt{2} \cdot \max \{\operatorname{range}(p)$, range $(q)\}$. Then, we can apply Lemma 5.2 (i) and (iii) to $p$ or $q$ whichever has a larger range and conclude that $\angle n_{\sigma}(p), p q>\pi / 2-4 \omega$. It follows that $\angle n_{\sigma}(p), V_{p q}<4 \omega$.

### 5.2.2 Lower Bounds

In this section we give the proofs that MeshPSC maintains inductively a lower bound of $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ on the distances among the points in $S$. The next lemma shows that the lower bound holds after step 1 of MeshPSC, i.e., protecting the vertices and 1-faces and inserting a point in each 2 -face outside the protecting balls.

Lemma 5.10 Let $S$ be the admissible point set obtained at the end of Step 1 of MeshPSC. For any $p, q \in S,\|p-q\| \geqslant$ lfs $_{\varepsilon}^{*}$.

Proof If $p$ and $q$ belong to different 2-faces, $\|p-q\| \geqslant \max \{g(p), g(q)\} \geqslant$ $\max \{f(p), f(q)\}$ which is greater than lfs* ${ }_{\varepsilon}^{*}$ by Lemma 5.1. Suppose that $p$ and $q$ belong to the same 2 -face. So $p$ or $q$ is weighted. By Lemma 5.1, the radii of protecting balls are greater than lfs* . If $p$ or $q$ is unweighted, say $q$, then $q$ lies outside $B_{p}$ and so $\|p-q\| \geqslant \operatorname{radius}\left(B_{p}\right)>\mathrm{lfs}_{\varepsilon}^{*}$. If both are weighted and $p$ and $q$ are nonadjacent, Lemma 3.1(v) implies that $\|p-q\|>$ lfs $_{\varepsilon}^{*}$. If $p$ and $q$ are weighted and adjacent, by Lemma 3.1(iv)(a), $q \notin$ int $B_{p}$ and so $\|p-q\| \geqslant \operatorname{radius}\left(B_{p}\right)>\operatorname{lfs}_{\varepsilon}^{*}$.

Next, we show that any of the procedure calls within FindViolation $(p, \sigma)$ preserves the lower bound of $0.03 \mathrm{lfs}_{\varepsilon}^{*}$. Multilntersection and NoDisk do so only when the lower bound has been preserved so far. Infringed, SurfaceNormal, and CurveNormal preserve the lower bound without requiring it as a precondition.

Lemma 5.11 Let $S$ be the current admissible point set. If $\|a-b\| \geqslant 0.03$ lfs $_{\varepsilon}^{*}$ for any $a, b \in S$ and Multilntersection $(p, \sigma)$ returns a point $x$, the distance between $x$ and any point in $S$ is at least $0.03 \mathrm{lfs}_{\varepsilon}^{*}$.

Proof The point $x$ belongs to $\left.V_{t}\right|_{\sigma}$ for some triangle $t \in \operatorname{star}(p, \sigma)$ such that $V_{t}$ intersects $\sigma$ more than once. Let $\varphi$ be the function that returns the weighted distance between $p$ and points on $V_{t}$. By the working of Multilntersection $(p, \sigma), \varphi(x)$ is the largest among all points in $\left.V_{t}\right|_{\sigma}$. Assume to the contrary that the minimum distance between $x$ and the points in $S$ is less than 0.03 lfs $_{\varepsilon}^{*}$. So $\varphi(x)<0.03$ lfss $_{\varepsilon}^{*}$ too. Let $y$ be any point in $\left.V_{t}\right|_{\sigma}$ other than $x$. Because $\varphi(y) \leqslant \varphi(x)<0.03$ lfs $_{\varepsilon}^{*}$, Lemma 5.8 im plies that $\max \{\|p-x\|,\|p-y\|\}<\sqrt{2}$ range $(p)$. Then Lemma 5.2(iii) implies that $\angle n_{\sigma}(p), x y>\pi / 2-2 \omega$. However, since ortho $(t) \leqslant \varphi(x)<0.03$ lfs $_{\varepsilon}^{*}$, by Lemma 5.7, $\angle n_{\sigma}(p), x y=\angle n_{\sigma}(p), V_{t}<26 \omega<\pi / 2-2 \omega$, a contradiction.

Lemma 5.12 Let $S$ be the current admissible point set. If $\operatorname{Infringed}(p, \sigma)$ returns $a$ point $x$, the distance between $x$ and any point in $S$ is at least $0.03 \mathrm{lfs}_{\varepsilon}^{*}$.

Proof The point $x$ belongs to $V_{p q}$ for some edge $p q \in \operatorname{star}(p, \sigma)$ that certifies that ( $p, \sigma$ ) is infringed. In other words, there is a ball $B$ centered at $x$ orthogonal to $p$
and $q$, and the weighted distances of $B$ from all weighted and unweighted vertices is nonnegative. In particular, this means that $B$ does not contain any point in $S$, weighted or unweighted. Therefore, it suffices to show that radius $(B) \geqslant 0.03 \mathrm{lfs}_{\varepsilon}^{*}$.

If $q \in \sigma, p$ and $q$ must be nonadjacent weighted points in bd $\sigma$. Then, by Lemma 3.1(v) and Lemma 5.1, the distance between $B_{p}$ and $B_{q}$ is at least $0.06 \mathrm{lfs}_{\varepsilon}^{*}$. So $\operatorname{radius}(B) \geqslant 0.03 \mathrm{lfs}_{\varepsilon}^{*}$. The other case is that $q \notin \sigma$ and so $\|p-q\| \geqslant$ $\max \{g(p), g(q)\}$. If $p$ is weighted, by Lemma 3.1(ii), $\operatorname{radius}\left(B_{p}\right)<5 \lambda g(p)<$ $g(p) / 4 \leqslant\|p-q\| / 4$. Similarly, if $q$ is weighted, $\operatorname{radius}\left(B_{q}\right)<\|p-q\| / 4$. Therefore, irrespective of whether any of $p$ and $q$ is weighted, $B$ must fill a gap of width at least $\|p-q\| / 2 \geqslant g(p) / 2$. It follows that radius $(B) \geqslant g(p) / 4 \geqslant f(p) / 4$, which is greater than $\mathrm{lfs}_{\varepsilon}^{*}$ by Lemma 5.1.

Lemma 5.13 Let $S$ be the current admissible point set. If $\operatorname{SurfaceNormal}\left(p, \sigma, \phi_{s}\right)$ returns a point $x$, the distance between $x$ and any point in $S$ is at least $\mathrm{lfs}_{\varepsilon}^{*}$.

Proof By definition, $\left.x \in V_{p}\right|_{\sigma}$ and $\angle n_{\sigma}(p), n_{\sigma}(x)=\phi_{s}>4 \omega$. If the minimum distance between $x$ and the points in $S$ is less than lfs* , then $\|p-x\|<\sqrt{2} \operatorname{range}(p)$ by Lemma 5.8. But then Lemma 5.2(i) implies that $\angle n_{\sigma}(p), n_{\sigma}(x)<2 \omega$, a contradiction.

Lemma 5.14 Let $S$ be the current admissible point set. If $\operatorname{lnfringed}(p, \sigma)$ and SurfaceNormal $\left(p, \sigma, \phi_{s}\right)$ return null and $\operatorname{CurveNormal}\left(p, \sigma, \phi_{c}\right)$ returns a point $x$, the distance between $x$ and any point in $S$ is at least $\mathrm{lfs}_{\varepsilon}^{*}$.

Proof By definition, $\left.x \in V_{p q}\right|_{\sigma}$ for some edge $p q \in \operatorname{star}(p, \sigma)$. As $\operatorname{Infringed}(p, \sigma)$ returns null, $q \in \sigma$. Assume to the contrary that the minimum distance between $x$ and the points in $S$ is less than $\mathrm{lfs}_{\varepsilon}^{*}$. By Lemma $5.9, \angle n_{\sigma}(p), \vec{d}<4 \omega$, where $\vec{d}$ is the projection of $n_{\sigma}(p)$ onto the plane of $V_{p q}$. Since $\operatorname{SurfaceNormal}\left(p, \sigma, \phi_{s}\right)$ returns null, $\angle n_{\sigma}(p), n_{\sigma}(x)<\phi_{s}$, which implies that $\angle n_{\sigma}(x), \vec{d}<\phi_{s}+4 \omega$. However, as CurveNormal $\left(p, \sigma, \phi_{c}\right)$ returns $x, \angle n_{\sigma}(x), \vec{d} \geqslant \phi_{c}>\phi_{s}+4 \omega$, a contradiction.

The case for $\operatorname{NoDisk}(p, \sigma)$ is more complicated. Let $p$ be a point on a 2 -face $\sigma$. We first show that $\mathrm{bd}\left(V_{p} \cap \sigma\right)$ is a closed curve under certain conditions. We proved a similar result earlier [14] in the context of meshing a smooth closed surface. That proof can be carried over after some modifications. The details can be found in Appendix D.

Lemma 5.15 Let $S$ be the current admissible point set. Assume that $\|a-b\| \geqslant$ $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. Let $p$ be a point in $S \cap \sigma$ for some 2 -face $\sigma$. Suppose that Infringed $(p, \sigma)$ and CurveNormal $\left(p, \sigma, \phi_{c}\right)$ return null and $\operatorname{size}(t, \sigma)<0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any triangle $t \in \operatorname{star}(p, \sigma)$. Then, $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ is a closed curve.

We can then show that any point returned by $\operatorname{NoDisk}(p, \sigma)$ is far from existing vertices.

Lemma 5.16 Let $S$ be the current admissible point set. Assume that $\|a-b\| \geqslant$ $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. Let $p$ be a point in $S \cap \sigma$ for some 2 -face $\sigma$. Suppose
that $\operatorname{Multilntersection~}(p, \sigma)$, Infringed $(p, \sigma)$, and $\operatorname{CurveNormal}\left(p, \sigma, \phi_{c}\right)$ return null. If $\operatorname{NoDisk}(p, \sigma)$ returns a point $x$, the distance between $x$ and any point in $S$ is at least $0.03 \mathrm{lfs}_{\varepsilon}^{*}$.

Proof If the lemma is false, the minimum distance between $x$ and the points in $S$ is less than $0.03 \mathrm{lfs}_{\varepsilon}^{*}$. So is the minimum weighted distance. It follows from the working of $\operatorname{NoDisk}(p, \sigma)$ that $\operatorname{size}(t, \sigma)<0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any triangle $t \in \operatorname{star}(p, \sigma)$. Then, Lemma 5.15 implies that bd $\left.V_{p}\right|_{\sigma}$ is a closed curve. Furthermore, bd $\left.V_{p}\right|_{\sigma}$ is not contained in a single facet of $V_{p}$ because CurveNormal $\left(p, \sigma, \phi_{c}\right)$ returns null. Then, because Multilntersection $(p, \sigma)$ returns null, the triangles in $\operatorname{star}(p, \sigma)$ form a topological disk by the duality between $\left.\mathrm{bd} V_{p}\right|_{\sigma}$ and $\operatorname{star}(p, \sigma)$. But then $\operatorname{NoDisk}(p, \sigma)$ should have returned null, a contradiction.

### 5.3 Termination

We use the distance lower bounds proved in the last section to show the termination of MeshPSC. Furthermore, we establish some topological properties of the resulting restricted Voronoi diagram.

Theorem 5.1 (MeshPSC terminates) The following properties hold for each point $p$ in the final admissible point set.
(i) For any 1- or 2-face $\sigma, V_{p}$ intersects $\sigma$ only if $p \in \sigma$.
(ii) For any 2-face $\sigma$ and for any triangle $t \in \operatorname{star}(p, \sigma),\left.V_{t}\right|_{\sigma}$ is a single point.
(iii) For any 1- or 2-face $\sigma$ and for any edge $e \in \operatorname{star}(p, \sigma),\left.V_{e}\right|_{\sigma}$ is a topological ball of dimension $\operatorname{dim}(\sigma)-1$;
(iv) For any 1- or 2-face $\sigma$ containing $p,\left.V_{p}\right|_{\sigma}$ is a topological ball of dimension $\operatorname{dim}(\sigma)$.

Proof By Lemma 5.10, any two mesh vertices are at distance $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ or more at the end of step 1 of MeshPSC. Afterwards, whenever MeshPSC inserts a new point, its distance from any existing mesh vertex is at least $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ by Lemma 5.11, Lemma 5.12, Lemma 5.13, Lemma 5.14, and Lemma 5.16. Recall that PSC is compact by definition. So a standard packing argument can be used to claim termination.

By Lemma 5.3, $V_{p}$ intersects a 1 -face only if $p$ lies on it. Suppose that $V_{p}$ intersects a 2-face $\sigma$ that does not contain $p$. Recall that MeshPSC inserts an unweighted point in int $\sigma$ during initialization. Walking from $V_{p}$ to the Voronoi cell of this unweighted point, we must encounter two vertices $q \notin \sigma$ and $s \in \sigma$ such that the common facet $V_{q s}$ intersects $\sigma$. But then $\operatorname{Infringed}(s, \sigma)$ should return a point, contradicting the termination of MeshPSC. This proves (i).

The correctness of (ii) follows from the fact that Multilntersection is not applicable.
Let $\tau$ be a 1 -face. We have just shown that $\operatorname{star}(p, \tau)$ is nonempty only if $p \in \tau$. By Lemma 5.3, a facet of $V_{p}$ intersects $\tau$ only if the facet is between $p$ and an adjacent weighted point on $\tau$. Such a facet is $V_{e}$ for some edge $e \in \operatorname{star}(p, \tau)$. Lemma 5.3 further implies that $V_{e}$ intersects $\tau$ in one point. Let $\sigma$ be a 2 -face. By (i) again, $\operatorname{star}(p, \sigma)$ is nonempty only if $p \in \sigma$. For any edge $e \in \operatorname{star}(p, \sigma),\left.V_{e}\right|_{\sigma}$ is a collection of curve(s). There is no closed curve in $\left.V_{e}\right|_{\sigma}$ because $\operatorname{CurveNormal}\left(p, \sigma, \phi_{c}\right)$ returns
null. If there are two open curves in $\left.V_{e}\right|_{\sigma}$, at least three of their endpoints belong to bd $V_{e}$. Since Multilntersection returns null, these curve endpoints belong to distinct boundary edges of $V_{e}$. Each such curve endpoint gives rise to a triangle in $\operatorname{star}(p, \sigma)$ incident to $e$, implying that there are at least three triangles in $\operatorname{star}(p, \sigma)$ incident to $e$. This is a contradiction because $\operatorname{NoDisk}(p, \sigma)$ returns null. Hence, $\left.V_{e}\right|_{\sigma}$ is an open curve. This proves (iii).

Let $\tau$ be a 1 -face containing $p$. Lemma 5.3 implies that $\operatorname{bd} V_{p}$ intersects $\tau$ exactly twice if $p \in \operatorname{int} \tau$, and $\operatorname{bd} V_{p}$ intersects $\tau$ exactly once if $p$ is an endpoint of $\tau$. Therefore, $V_{p} \cap \tau$ is an open curve. Let $\sigma$ be a 2 -face containing $p$. Because $\operatorname{NoDisk}(p, \sigma)$ returns null, the union of the triangles in $\operatorname{star}(p, \sigma)$ is a topological disk. Since Multilntersection and CurveNormal return null, no two curves in bd $\left.V_{p}\right|_{\sigma}$ intersect the same edge of $V_{p}$, and no curve in bd $\left.V_{p}\right|_{\sigma}$ lies within a facet of $V_{p}$. Then, the duality between $\operatorname{star}(p, \sigma)$ and $\left.\mathrm{bd} V_{p}\right|_{\sigma}$ implies that $\left.\mathrm{bd} V_{p}\right|_{\sigma}$ is a closed curve. There is a direction $\vec{d}$ such that for any point $\left.z \in V_{p}\right|_{\sigma}, \angle \vec{d}, n_{\sigma}(z)<\pi / 2$. For example, since SurfaceNormal $\left(p, \sigma, \phi_{s}\right)$ returns null, we can choose $\vec{d}=n_{\sigma}(p)$. It has been proved in [14] that for such a 2 -manifold $\left.V_{p}\right|_{\sigma}$, its projection to a plane orthogonal to $\vec{d}$ is an injective map. Since the projected image is a planar bounded region with a closed boundary curve, it must be a topological disk. The injectivity of the projection makes it a homeomorphism between the projected image and $\left.V_{p}\right|_{\sigma}$. Hence, $\left.V_{p}\right|_{\sigma}$ is a topological disk. This proves (iv).

### 5.4 Topology Preservation

A CW-complex $\mathcal{R}$ is a collection of closed (topological) balls whose interiors are pairwise disjoint and whose boundaries are union of other closed balls in $\mathcal{R}$. A finite set $S \subset|\mathcal{D}|$ has the extended topological ball properties (extended TBP) for $\mathcal{D}$ if there is a CW-complex $\mathcal{R}$ with $|\mathcal{R}|=|\mathcal{D}|$ that satisfies the following conditions for each Voronoi face $F \in \operatorname{Vor} S$ intersecting $|\mathcal{D}|$ :
(C1) The restricted Voronoi face $F \cap|\mathcal{D}|$ is the underlying space of a CW-complex $\mathcal{R}_{F} \subseteq \mathcal{R}$.
(C2) The (closed) balls in $\mathcal{R}_{F}$ that intersect int $F$ are incident to a unique (closed) ball $b_{F} \in \mathcal{R}_{F}$.
(C3) $b_{F} \cap \mathrm{bd} F$ is a sphere of dimension $\operatorname{dim}\left(b_{F}\right)-1$.
(C4) For each $\ell$-ball $b \in \mathcal{R}_{F} \backslash\left\{b_{F}\right\}$ that intersects int $F, b \cap \operatorname{bd} F$ is an $(\ell-1)$-ball.
Figure 3 shows two examples of a Voronoi facet $F$ that satisfy the above conditions.

The result of Edelsbrunner and Shah [21] says that if $S$ has the extended TBP for $\mathcal{D}$, the underlying space of $\left.\operatorname{Del} S\right|_{\mathcal{D}}$ is homeomorphic to $|\mathcal{D}|$. Of course, to apply this result we would require a CW-complex with underlying space $|\mathcal{D}|$. We will see that Vor $S$ restricted to $\mathcal{D}$ provides such a CW-complex when our algorithm terminates.

We first show that the Voronoi faces of Vor $S$ satisfy three properties P1, P2, and P3 listed below at the termination of the algorithm. Let $F$ be a $k$-face of Vor $S$ where $F=V_{p_{1}} \cap \cdots \cap V_{p_{(4-k)}}$.

Fig. $3 F$ is a Voronoi facet. In (a), $F$ intersects a 2 -face in a closed topological interval (1-ball) which is $b_{F}$. Here $b_{F}$ intersects bd $F$ at two points, a 0 -sphere. In (b), $F$ intersects the 1-face in a single point which is $b_{F}$, and for $1 \leqslant i \leqslant 3, F \cap \sigma_{i}$ are closed topological 1-balls incident to $b_{F}$. Here $b_{F} \cap \mathrm{bd} F=\emptyset, \mathrm{a}-1$-sphere

(a)

(b)
(P1) If $F$ intersects an element $\sigma \in \mathcal{D}_{j}$, the intersection is a closed $(k+j-3)$-ball.
(P2) There is a unique element $\sigma_{F} \in \mathcal{D}$ such that the elements intersected by $F$ are $\sigma_{F}$ and those that contain $\sigma_{F}$ in their boundaries.
(P3) $\sigma_{F}$ contains the vertices $p_{1}, \ldots, p_{(4-k)}$.
Property P1 follows from the fact that our algorithm enforces TBP for each 1-face and 2-face (Theorem 5.1). Properties P2 and P3 follow from the following result.

Lemma 5.17 Let $F=V_{p_{1}} \cap \cdots \cap V_{p_{(4-k)}}$ be a $k$-face in Vor $S$ when MeshPSC terminates. Let $E_{F}$ be the set of elements in $\mathcal{D}$ that intersect $F$.
(i) For any $\sigma \in E_{F}, \sigma$ contains $p_{i}$ for $1 \leqslant i \leqslant 4-k$.
(ii) Let $\sigma_{F}$ be an element in $E_{F}$ of lowest dimension. For any $\sigma \in E_{F} \backslash\left\{\sigma_{F}\right\}, \sigma_{F} \subset$ $\operatorname{bd} \sigma$.

Proof For any $\sigma \in E_{F}$, since $\sigma$ intersects $F, \sigma$ intersects $V_{p_{i}}$ for $1 \leqslant i \leqslant 4-k$. So Theorem 5.1(i) implies that $\sigma$ contains $p_{i}$ for $1 \leqslant i \leqslant 4-k$. This proves (i). We conduct a case analysis depending on the dimension of $F$ to prove (ii).

Case 1: $F$ is a Voronoi cell $V_{p}$. Take any element $\sigma \in E_{F} \backslash\left\{\sigma_{F}\right\}$. By (i), $p \in \sigma_{F} \cap \sigma$ which implies that $\sigma_{F} \cap \sigma$ contains an element $\sigma^{\prime}$ in $E_{F}$. If $\sigma_{F} \not \subset \mathrm{bd} \sigma, \operatorname{dim}\left(\sigma^{\prime}\right) \leqslant$ $\operatorname{dim}\left(\sigma_{F}\right)-1$. But this contradicts the definition of $\sigma_{F}$.

Case 2: $F$ is a Voronoi facet $V_{p q}$. Since $p, q \in \sigma_{F}$ by (i), $\operatorname{dim}\left(\sigma_{F}\right) \geqslant 1$. If $p$ or $q$ lies in the interior of a 2-face, $\sigma_{F}$ is this 2-face and $E_{F}$ is the singleton set $\left\{\sigma_{F}\right\}$. So (ii) is trivially true. Suppose that $p, q \in\left|\mathcal{D}_{\leqslant 1}\right|$. We claim that $\sigma_{F}$ is a 1-face. Assume to the contrary that $\sigma_{F}$ is a 2 -face. So $p, q \in \operatorname{bd} \sigma_{F}$ as $p, q \in|\mathcal{D} \leqslant 1|$. The edge $p q$ belongs to $\left.\operatorname{Del} S\right|_{\sigma_{F}}$ as $V_{p q} \cap \sigma_{F}=F \cap \sigma_{F} \neq \emptyset$. The points $p$ and $q$ must be adjacent along bd $\sigma_{F}$; otherwise, $p q$ would trigger $\operatorname{Infringed}\left(p, \sigma_{F}\right)$ to insert a point, contradicting the termination of MeshPSC. As $p$ and $q$ are adjacent, by Lemma 5.3, $F=V_{p q}$ intersects the subcurve of $\operatorname{bd} \sigma_{F}$ between $p$ and $q$. Thus, some 1-face in $\operatorname{bd} \sigma_{F}$ belongs to $E_{F}$. But this contradicts the definition of $\sigma_{F}$. This proves our claim.

The vertices $p$ and $q$ are adjacent along the 1-face $\sigma_{F}$. If not, for some 2-face $\sigma^{\prime}$ containing $\sigma_{F}$ in its boundary, $p q$ would trigger $\operatorname{Infringed}\left(p, \sigma^{\prime}\right)$ to insert a point. This contradicts the termination of MeshPSC.

Since $p$ and $q$ are adjacent along $\sigma_{F}$, by our protecting ball placement strategy, $\sigma_{F}$ is the only 1-face that contains $p$ and $q$. Moreover, $\sigma_{F}$ belongs to the boundary of any 2-face containing $p$ and $q$. For any $\sigma \in E_{F} \backslash\left\{\sigma_{F}\right\}, \sigma$ is a 1- or 2-face containing
$p, q$ by (i). Consequently, since $\sigma \neq \sigma_{F}, \sigma$ must be a 2-face that contains $\sigma_{F}$ in its boundary.

Case 3: $F$ is a Voronoi edge $V_{p q s}$. As in case 2, if $p, q$, or $s$ lies in the interior of a 2-face, $\sigma_{F}$ is this 2-face, and $E_{F}$ is the singleton set $\left\{\sigma_{F}\right\}$. So (ii) is trivially true. We derive a contradiction for the case that $p, q, s \in\left|\mathcal{D}_{\leqslant 1}\right|$. In this case we can show as in case 2 that $\sigma_{F}$ must be a 1 -face. By (i), $p, q, s \in \sigma_{F}$. Since any three vertices on any 1-face cannot be mutually adjacent, two vertices in $\{p, q, s\}$ are nonadjacent along $\sigma_{F}$, say $p$ and $q$. But then the edge $p q$ would trigger $\operatorname{Infringed}\left(p, \sigma^{\prime}\right)$ to insert a point for some 2-face $\sigma^{\prime}$ whose boundary contains $\sigma_{F}$. This contradicts the termination of MeshPSC.

We show that conditions C1-C4 follow from P1 and P2. The proof depends on our assumption of the generic intersection property (GIP): every Voronoi face in Vor $S$ intersects an element of $\mathcal{D}$ transversally, if at all, at the termination of MeshPSC. The assumption of the GIP can be removed by employing a more elaborate analysis and symbolic perturbation in the algorithm; see [14] for details.

Theorem 5.2 The output of MeshPSC is homeomorphic to $|\mathcal{D}|$.
Proof We prove that $S$ has the extended TBP for $\mathcal{D}$ when MeshPSC terminates. Then, the result of Edelsbrunner and Shah implies the theorem. To apply the extended TBP we need a CW-complex whose underlying space is $|\mathcal{D}|$. Upon the termination of MeshPSC, we take $\mathcal{R}$ to be the complex formed by the intersection of the Voronoi faces in Vor $S$ with the elements of $\mathcal{D}$. So $\mathcal{R}$ is a CW-complex according to P1. It immediately follows that a $k$-face $F$ of $\operatorname{Vor} S$ intersects the CW-complex $\mathcal{R}$ in a CWcomplex $\mathcal{R}_{F} \subseteq \mathcal{R}$ satisfying C 1 .

Define $\sigma_{F}$ as in the statement of Lemma 5.17. We identify $b_{F}$ as $\sigma_{F} \cap F$. By the assumption of GIP, $\sigma_{F}$ intersects int $F$, and so $b_{F}$ intersects int $F$. Condition C2 then follows from P2.

If bd $b_{F}$ intersects int $F, \operatorname{bd} \sigma_{F}$ intersects $F$ too. But this would contradict P2 which states that any element other than $b_{F}$ that intersects $F$ contains $\sigma_{F}$ in its boundary. Therefore, bd $b_{F}$ must be contained in bd $F$. The assumption of GIP allows us to conclude that $b_{F} \cap \mathrm{bd} F=\mathrm{bd} b_{F}$. Thus, $b \cap \mathrm{bd} F=\mathrm{bd} b_{F}$ is a sphere of dimension $\operatorname{dim}\left(b_{F}\right)-1$. This establishes condition C3.

Take any ball $b \in \mathcal{R}_{F} \backslash\left\{b_{F}\right\}$ that intersects int $F$. Let $\sigma$ be the element in $\mathcal{D}$ such that $b=\sigma \cap F$. We claim that $\operatorname{bd} \sigma \cap \operatorname{int} F$ is an open $(\ell-1)$-ball, where $\ell=$ $\operatorname{dim}(F)+\operatorname{dim}(\sigma)-3$. The proof involves a case analysis depending on $\operatorname{dim}\left(\sigma_{F}\right)$.

- If $\sigma_{F}$ is a 2-face, $\sigma$ does not exist by P 2 because $\mathcal{D}$ does not contain any element with dimension higher than two. So there is nothing to prove.
- If $\sigma_{F}$ is a 1-face, P 2 implies that $\sigma$ is a 2-face, $F$ does not contain any vertex of $\sigma$, and $F$ does not intersect any 1-face other than $\sigma_{F}$. It follows that bd $\sigma \cap \operatorname{int} F=$ $\sigma_{F} \cap \operatorname{int} F$ which by P 1 is an open $(\ell-1)$-ball as $\operatorname{dim}\left(\sigma_{F}\right)=\operatorname{dim}(\sigma)-1$.
- If $\sigma_{F}$ is a vertex in $\mathcal{D}_{0}, F$ must be the Voronoi cell owned by $\sigma_{F}$. So $F$ does not contain any vertex of $\sigma$ other than $\sigma_{F}$. By P 2 , any 1 -face intersected by $F$ is incident to $\sigma_{F}$. If $\sigma$ is a 1-face, bd $\sigma \cap \operatorname{int} F=\sigma_{F}$, which is an open $(\ell-1)$-ball as $\ell=1$ in this case. If $\sigma$ is a 2 -face, $\operatorname{bd} \sigma \cap \operatorname{int} F$ is equal to $\left(\sigma_{1} \cup \sigma_{2}\right) \cap \operatorname{int} F$, where
$\sigma_{1}$ and $\sigma_{2}$ are the two 1 -faces in $\operatorname{bd} \sigma$ incident to $\sigma_{F}$. Since the other endpoints of $\sigma_{1}$ and $\sigma_{2}$ are outside $F,\left(\sigma_{1} \cup \sigma_{2}\right) \cap \operatorname{int} F$ is an open curve which is an open $(\ell-1)$-ball as $\ell=2$ in this case.
By P1, $b=\sigma \cap F$ is a closed $\ell$-ball, where $\ell=\operatorname{dim}(F)+\operatorname{dim}(\sigma)-3$. So $\operatorname{bd} b$ is an $(\ell-1)$-sphere. Observe that $\operatorname{bd} b=(\mathrm{bd} b \cap \operatorname{int} F) \cup(\mathrm{bd} b \cap \mathrm{bd} F)$. Furthermore, $\mathrm{bd} b=(\mathrm{bd} b \cap \operatorname{int} F)$ and $\mathrm{bd} b \cap \mathrm{bd} F$ are disjoint, $\operatorname{bd} b \cap \mathrm{bd} F=b \cap \mathrm{bd} F$, and $\mathrm{bd} b \cap$ int $F=\operatorname{bd} \sigma \cap \operatorname{int} F$. We have shown in the above that $\operatorname{bd} \sigma \cap \operatorname{int} F$ is an open $(\ell-1)$ ball. Hence, $b \cap \mathrm{bd} F$ must be a closed $(\ell-1)$-ball in order to merge with the open $(\ell-1)$-ball bd $\sigma \cap \operatorname{int} F$ to form the $(\ell-1)$-sphere bd $b$. This proves condition C4.

Non-smooth Features Following the proof of Edelsbrunner and Shah [21] one can construct a homeomorphism $h$ between the underlying spaces of $\mathcal{D}$ and $\left.\operatorname{Del} S\right|_{\mathcal{D}}$ such that $h$ respects each stratum. That is, the restriction of $h$ to $\left|\mathcal{D}_{i}\right|$ is a homeomorphism to the underlying space of $\left.\operatorname{Del} S\right|_{\mathcal{D}_{i}}$. Property P3 ensures that $\left.\operatorname{Del} S\right|_{\mathcal{D}_{i}}$ has all vertices in $\mathcal{D}_{i}$. This property ensures the preservation of non-smooth features. For example, a 1 -face in $\mathcal{D}$ is meshed with a set of Delaunay edges connecting consecutive points sampled on it thereby preserving the "non-smoothness" of the 1-face in the output.

## 6 Mesh Quality Improvements

We introduce two subroutines that enhance MeshPSC to offer bounds on the aspect ratios, normal variation, and dihedral angles in the output mesh. For a triangle $t$, the radius-edge ratio is defined to be the ratio of the circumradius to the shortest edge length of $t$. It is known that the radius-edge ratio of a triangle is bounded if and only if the aspect ratio is bounded. For a point $p$ on a 2 -face $\sigma$, the first subroutine Shape eliminates triangles in $\operatorname{star}(p, \sigma)$ with unweighted vertices and radius-edge ratios at least 1 ; the second subroutine TriangleNormal eliminates triangles in $\operatorname{star}(p, \sigma)$ whose normal deviates from $n_{\sigma}(p)$ by $26 \omega$ or more. Notice that we do not offer any guarantee on the shape of triangles incident to weighted vertices. The pseudocodes of Shape and TriangleNormal are given below.

## Shape ( $p, \sigma$ )

1. If there is a triangle $t \in \operatorname{star}(p, \sigma)$ whose vertices are unweighted and radiusedge ratio is greater than or equal to 1 , return $\left.V_{t}\right|_{\sigma}$.
2. Otherwise, return null.

## TriangleNormal $(p, \sigma)$

1. If there is a triangle $t \in \operatorname{star}(p, \sigma)$ such that $\angle n_{\sigma}(p), V_{t} \geqslant 26 \omega$, return $\left.V_{t}\right|_{\sigma}$.
2. Otherwise, return null.

We modify FindViolation $(p, \sigma)$ to call the subroutines Multilntersection $(p, \sigma)$, $\operatorname{Infringed}(p, \sigma), \operatorname{SurfaceNormal}\left(p, \sigma, \phi_{s}\right), \operatorname{CurveNormal}\left(p, \sigma, \phi_{c}\right)$, Shape $(p, \sigma)$, and TriangleNormal $(p, \sigma)$ in this order. If any call returns a point, stop and return that point. Otherwise, return null. The enhanced algorithm works like MeshPSC by calling the enhanced FindViolation until the admissible point set stops growing. We call this enhanced algorithm QualMeshPSC.

By Theorem 5.1, when FindViolation $(p, \sigma)$ calls $\operatorname{Shape}(p, \sigma)$ or TriangleNormal $(p, \sigma),\left.V_{t}\right|_{\sigma}$ is a point for any triangle $t \in \operatorname{star}(p, \sigma)$. Thus, the subroutines Shape and TriangleNormal are well-defined. The next two lemmas show that termination is still guaranteed.

Lemma 6.1 Let $S$ be the current admissible point set. Assume that $\|a-b\| \geqslant$ $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. If FindViolation $(p, \sigma)$ calls $\operatorname{Shape}(p, \sigma)$ and $\operatorname{Shape}(p, \sigma)$ returns a point $x$, the distance between $x$ and any point in $S$ is at least $0.03 \mathrm{lfs}_{\varepsilon}^{*}$.

Proof The point $x$ returned is $\left.V_{t}\right|_{\sigma}$ for some triangle $t \in \operatorname{star}(p, \sigma)$. Since the radiusedge ratio of $t$ is at least 1 , the distance from $x$ to the vertices of $t$ is at least the shortest edge length of $t$. The invocations of Multilntersection, Infringed, SurfaceNormal, and CurveNormal have kept a distance lower bound of $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ among the vertices. So the distances from $x$ to the vertices of $t$ is at least $0.03 \mathrm{lfs}_{\varepsilon}^{*}$. Because the vertices of $t$ are unweighted, $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ is also a lower bound on the minimum weighted distance between $x$ and the points in $S$. In turn, this implies that the distance between $x$ and any point in $S$ is at least $0.03 \mathrm{lfs}_{\varepsilon}^{*}$.

Lemma 6.2 Let $S$ be the current admissible point set. Assume that $\|a-b\| \geqslant$ $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. If FindViolation $(p, \sigma)$ calls $\operatorname{TriangleNormal}(p, \sigma)$ and TriangleNormal $(p, \sigma)$ returns a point $x$, the distance between $x$ and any point in $S$ is greater than $0.03 \mathrm{lfs}_{\varepsilon}^{*}$.

Proof Let $t$ be the triangle in $\operatorname{star}(p, \sigma)$ such that $\left.V_{t}\right|_{\sigma}=x$. The contrapositive of Lemma 5.7 implies that ortho $(t)>0.03 \mathrm{lfs}_{\varepsilon}^{*}$. So the weighted distance between $x$ and any point in $S$ is greater than $0.03 \mathrm{lfs}_{\varepsilon}^{*}$. So is the distance between $x$ and any point in $S$.

Because a distance lower bound is maintained by Shape and TriangleNormal, QualMeshPSC terminates. The guarantees in Theorem 5.1 and Theorem 5.2 are preserved as Multilntersection, Infringed, SurfaceNormal, and CurveNormal are inapplicable at the termination of QualMeshPSC.

The inapplicability of Shape implies that all output triangles with unweighted vertices have radius-edge ratio less than 1 . The angles of such triangles lie in the range $\left(\frac{\pi}{6}, \frac{2 \pi}{3}\right)$. There is no shape guarantee for output triangles incident on weighted vertices.

TriangleNormal ensures that the normal of any triangle deviates from the surface normals at its vertices by less than $26 \omega$. Furthermore, we prove below that for any 2-face $\sigma$, the dihedral angle between any pair of triangles in $\left.\operatorname{Del} S\right|_{\sigma}$ sharing an edge is greater than $\pi-52 \omega$. Notice that for any edge in $\left.\operatorname{Del} S\right|_{\sigma}$ with both endpoints weighted, the edge is incident to only one triangle in $\left.\operatorname{Del} S\right|_{\sigma}$; and for any edge in $\left.\operatorname{Del} S\right|_{\sigma}$ with an unweighted endpoint, the edge is incident to two triangles in $\left.\operatorname{Del} S\right|_{\sigma}$.

Let $t_{1}$ and $t_{2}$ be two triangles in $\left.\operatorname{Del} S\right|_{\sigma}$ that share an edge $p q$. For $i \in\{1,2\}$, let $z_{i}$ denote $\left.V_{t_{i}}\right|_{\sigma}$, and let $\vec{d}_{i}$ be a unit vector parallel to $V_{t_{i}}$ and making an acute angle with $n_{\sigma}\left(z_{i}\right)$. TriangleNormal ensures that $\angle V_{t_{1}}, V_{t_{2}} \leqslant \angle n_{\sigma}(p), V_{t_{1}}+\angle n_{\sigma}(p), V_{t_{2}}<52 \omega$. Consequently, the dihedral angle between $t_{1}$ and $t_{2}$ is either less than $52 \omega$ or greater
than $\pi-52 \omega$. To complete the argument, it suffices to show that both $t_{1}$ and $t_{2}$ can be oriented in the clockwise order as seen from infinity in $\vec{d}_{1}$ such that $p q$ is assigned opposite orientations.

Since SurfaceNormal $\left(p, \sigma, \phi_{s}\right)$ returns null, $\angle n_{\sigma}(p), n_{\sigma}\left(z_{i}\right)<\phi_{s}<\pi / 16$. So

$$
\begin{align*}
\angle n_{\sigma}\left(z_{i}\right), \vec{d}_{i} & =\angle n_{\sigma}\left(z_{i}\right), V_{t_{i}} \\
& \leqslant \angle n_{\sigma}(p), V_{t_{i}}+\angle n_{\sigma}(p), n_{\sigma}\left(z_{i}\right) \\
& <26 \omega+\phi_{s} \\
& <\pi / 2 . \tag{1}
\end{align*}
$$

Denote by $O_{i}$ the clockwise ordering of the three restricted Voronoi cells locally around $z_{i}$ if we view from infinity in $\vec{d}_{i}$. As $n_{\sigma}\left(z_{i}\right), \vec{d}_{i}<\pi / 2, O_{i}$ is identical to the clockwise ordering of the restricted Voronoi cells locally around $z_{i}$ as seen from infinity in $n_{\sigma}\left(z_{i}\right)$.

If we view from infinity in $\vec{d}_{i}$, the clockwise ordering of $t_{i}$ is consistent with the clockwise ordering of the three Voronoi cells incident to $V_{t_{i}}$. As $n_{\sigma}\left(z_{i}\right), \vec{d}_{i}<\pi / 2$, this ordering is consistent with the clockwise ordering of the three restricted Voronoi cells locally around $z_{i}$ as seen from infinity in $n_{\sigma}\left(z_{i}\right)$. We conclude that $O_{i}$ is consistent with the clockwise ordering of $t_{i}$ as seen from infinity in $\vec{d}_{i}$.

By Theorem 5.1, $\left.V_{p q}\right|_{\sigma}$ is an open curve with endpoints $z_{1}$ and $z_{2}$. Therefore, the ordering of the two restricted Voronoi cells incident to $\left.V_{p q}\right|_{\sigma}$ in $O_{1}$ is the reverse of that in $O_{2}$. This implies that $p q$ is assigned opposite orientations when we orient $t_{i}$ in the clockwise order as viewed from $\vec{d}_{i}$ for $i \in\{1,2\}$. Since $\operatorname{SurfaceNormal}\left(p, \sigma, \phi_{s}\right)$ returns null,

$$
\begin{aligned}
\angle \vec{d}_{1}, \vec{d}_{2} & \leqslant \angle n_{\sigma}\left(z_{1}\right), \vec{d}_{1}+\angle n_{\sigma}\left(z_{2}\right), \vec{d}_{2}+\angle n_{\sigma}(p), n_{\sigma}\left(z_{1}\right)+\angle n_{\sigma}(p), n_{\sigma}\left(z_{2}\right) \\
& <\angle n_{\sigma}\left(z_{1}\right), \vec{d}_{1}+\angle n_{\sigma}\left(z_{2}\right), \vec{d}_{2}+2 \phi_{s} \\
& \stackrel{(1)}{<} 52 \omega+4 \phi_{s} \\
& <\pi / 2 .
\end{aligned}
$$

So the clockwise ordering of $t_{2}$ remains the same if we change the viewpoint to infinity in $\vec{d}_{1}$. In all, if we orient $t_{1}$ and $t_{2}$ in the clockwise order as seen from $\vec{d}_{1}, p q$ is assigned two opposite orientations.

We summarize with the following theorem.
Theorem 6.1 Let $\omega \in(0,0.01]$. QualMeshPSC terminates with the following guarantees.

- The output mesh is homeomorphic to $|\mathcal{D}|$.
- Each mesh triangle with unweighted vertices has radius-edge ratio less than 1.
- Let $S$ be the output vertex set. For each element $\sigma \in \mathcal{D}$, the vertices of $\left.\operatorname{Del} S\right|_{\sigma}$ belong to $\sigma$, and $\left.\operatorname{Del} S\right|_{\sigma}$ is homeomorphic to $\sigma$.
- For each mesh triangle, the angle between its normal and the surface normal at any of its vertex is less than $26 \omega$.
- For each mesh edge with an unweighted endpoint, the two mesh triangles incident to it make a dihedral angle greater than $\pi-52 \omega$.

## 7 Conclusions

We have presented a Delaunay refinement algorithm to mesh PSC which preserves topology as well as non-smooth features. We did not handle explicitly threedimensional elements in PSC. Our algorithm can be extended to handle these inputs. This will require further analysis along the line of [27, 30]. Our bound of 0.01 for $\lambda$ and $\omega$ is very small. So is the lower bound of $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ on the distances among the points inserted during Delaunay refinement, where $\varepsilon=\lambda \omega / 2500$. We believe that these pessimistic bounds are not the tightest possible and that the algorithm performs better in practice. A main question is how to make this algorithm practical. The main bottlenecks in practice are the surface normal and curve normal variation tests. Can these be eliminated or replaced with some other easier computations? Some answer to this question has been provided in [13] recently. We propose to handle parametric surfaces by first implicitizing them [24]. It is an interesting question whether our algorithm can be adapted to work directly with parametric surfaces. Our analysis guarantees homeomorphism between the input and the output. A stronger and more desirable condition would be to ensure an isotopy between the two. Does it require a different approach? Or, is it true that topological ball property indeed guarantees an isotopy at least for surfaces in three dimensions? We leave these questions as open.

## Appendix A: Background Results

Proof of Lemma 1.1 If $\sigma$ is a 1-face, $B(x, r) \cap \operatorname{mani}(\sigma)$ may be split by the endpoints of $\sigma$ into at most three subcurves, one of which is $B(x, r) \cap \sigma$. Suppose that $\sigma$ is a 2 -face. If $x \in \operatorname{int} \sigma$, since $B(x, r)$ avoids 1 -faces in this case by assumption, $B(x, r) \cap \sigma=B(x, r) \cap \operatorname{mani}(\sigma)$, and we are done. Suppose that $x \in \operatorname{bd} \sigma$. We claim that $B(x, r) \cap \mathrm{bd} \sigma$ is an open curve.

By assumption, $B(x, r)$ avoids any 1-face that does not contain $x$. If $x$ is incident to only one 1-face $\sigma_{1}$ (i.e., $x \in \operatorname{int} \sigma_{1}$ ), $B(x, r) \cap \mathrm{bd} \sigma=B(x, r) \cap \sigma_{1}$, and we have just shown that $B(x, r) \cap \sigma_{1}$ is an open curve. If $x$ is a common endpoint of two 1-faces $\sigma_{1}$ and $\sigma_{2}$ in bd $\sigma, B(x, r)$ does not contain any vertex of $\sigma_{i}$ other than $x$ as $B(x, r)$ avoids other 1-faces by assumption. We know that $B(x, r) \cap \sigma_{1}$ and $B(x, r) \cap \sigma_{2}$ are open curves, and so they concatenate to form one open curve. This proves our claim.

Since $B(x, r) \cap \mathrm{bd} \sigma$ is an open curve, it splits $B(x, r) \cap \operatorname{mani}(\sigma)$ into two topological disks, one of which is $B(x, r) \cap \sigma$.

Proof of Lemma 1.2 We use $\mathcal{C}$ to denote $H \cap B \cap \operatorname{mani}(\sigma)$. No curve in $\mathcal{C}$ is closed. Otherwise, the tangent to some point $z \in \mathcal{C}$ would be parallel to the projection $\vec{d}$ of $n_{\sigma}(x)$ on $H$, implying that $\angle n_{\sigma}(x), n_{\sigma}(z) \geqslant \angle n_{\sigma}(z), \vec{d}-\angle n_{\sigma}(x), \vec{d} \geqslant \pi / 2-\theta$. But
this is a contradiction because $\angle n_{\sigma}(x), n_{\sigma}(z)<\theta$. Notice that the endpoints of each curve in $\mathcal{C}$ lie on the boundary of $B$.

Notice that $y$ is the center of $H \cap B$ and some curve in $\mathcal{C}$ passes through $y$. Assume to the contrary that $\mathcal{C}$ consists of at least two open curves. Then, there exists a concentric disk $D$ inside the disk $H \cap B$ such that $D$ is tangent to some curve in $\mathcal{C}$ at a point $z$. Let $\ell$ be the support line of $y z$. Since $\ell$ intersects $B \cap \operatorname{mani}(\sigma)$ at $y$ and $z$, we can find a point $z^{\prime} \in \ell \cap B \cap \operatorname{mani}(\sigma)$ such that $z$ and $z^{\prime}$ are consecutive intersections points in $\ell \cap B \cap \operatorname{mani}(\sigma)$. As $B$ is convex, $z$ and $z^{\prime}$ are also consecutive intersection points in $\ell \cap \operatorname{mani}(\sigma)$. We have $\angle n_{\sigma}(z), \ell=\angle n_{\sigma}(z), H \leqslant \angle n_{\sigma}(x), H+\angle n_{\sigma}(x), n_{\sigma}(z)<$ $2 \theta$ by assumption. Also, $\angle n_{\sigma}\left(z^{\prime}\right), \ell \leqslant \angle n_{\sigma}(z), \ell+\angle n_{\sigma}(z), n_{\sigma}\left(z^{\prime}\right) \leqslant \angle n_{\sigma}(z), \ell+$ $\angle n_{\sigma}(x), n_{\sigma}(z)+\angle n_{\sigma}(x), n_{\sigma}\left(z^{\prime}\right)<4 \theta$. If we walk along $\ell$, we enter mani $(\sigma)$ at $z$ and exit mani $(\sigma)$ at $z^{\prime}$ or vice versa. We conclude that $\angle n_{\sigma}(z), n_{\sigma}\left(z^{\prime}\right)>\pi-6 \theta$ because $n_{\sigma}(z)$ and $n_{\sigma}\left(z^{\prime}\right)$ are outward surface normals. But this is a contradiction because $\angle n_{\sigma}(z), n_{\sigma}\left(z^{\prime}\right) \leqslant \angle n_{\sigma}(x), n_{\sigma}(z)+\angle n_{\sigma}(x), n_{\sigma}\left(z^{\prime}\right)<2 \theta \leqslant \pi-6 \theta$ as $\theta \leqslant \pi / 8$.

Proof of Lemma 1.3 Consider (i). We claim that $z$ lies strictly inside the double cone with apex $y$, angular aperture $2 \theta$, and axis through $y$ parallel to the tangent to $\operatorname{mani}(\sigma)$ at $x$. This claim immediately implies that $\angle n_{\sigma}(x), y z>\pi / 2-\theta$. Assume to the contrary that the claim is false. Since $\angle n_{\sigma}(x), n_{\sigma}(y)<\theta$ by assumption, the tangent to mani $(\sigma)$ at $y$ lies strictly inside the double cone. This implies that if we walk along the subcurve of $B(x, r) \cap \operatorname{mani}(\sigma)$ from $y$ to $z$, we stay inside the double cone initially. We must reach the double cone boundary for the first time at some point $z_{1}$ after leaving $y$. Let $H$ be the plane tangent to the double cone at $z_{1}$. We translate $H$ to a plane that is tangent to the subcurve between $y$ and $z_{1}$ at a point $z_{2}$. So $\angle n_{\sigma}(x), n_{\sigma}\left(z_{2}\right) \geqslant \theta$. Because $z_{2}$ lies on the subcurve between $y$ and $z_{1}, z_{2} \in$ $B(x, r) \cap \operatorname{mani}(\sigma)$. So by assumption, $\angle n_{\sigma}(x), n_{\sigma}\left(z_{2}\right)<\theta$, a contradiction.

Consider (ii). We are done if $\angle n_{\sigma}(x), y z>\pi / 2-\theta$ for any point $z \in B\left(x, \frac{1}{3} r\right) \cap$ $\operatorname{mani}(\sigma)$. Otherwise, because $B\left(x, \frac{1}{3} r\right) \cap \operatorname{mani}(\sigma)$ is connected, by continuity, there exists a point $z_{1} \in B\left(x, \frac{1}{3} r\right) \cap \operatorname{mani}(\sigma)$ such that $\angle n_{\sigma}(x), y z_{1}=\pi / 2-\theta$. Let $H$ be the plane containing $y z_{1}$ and parallel to $n_{\sigma}(x)$. Notice that $B\left(y,\left\|y-z_{1}\right\|\right) \subset$ $B\left(y, \frac{2}{3} r\right) \subset B(x, r)$. By Lemma 1.2, $H \cap B\left(y, \frac{2}{3} r\right) \cap \operatorname{mani}(\sigma)$ is an open curve, and let $\xi$ be its subcurve between $y$ and $z_{1}$. The tangent to $\xi$ at some point $z_{2}$ is parallel to $y z_{1}$ and thus it makes an angle $\pi / 2-\theta$ with the support line of $n_{\sigma}(x)$. So $\angle n_{\sigma}(x), n_{\sigma}\left(z_{2}\right) \geqslant \theta$. But this is a contradiction because $\angle n_{\sigma}(x), n_{\sigma}\left(z_{2}\right)<\theta$ by assumption.

## Appendix B: The Computation of $d_{\omega}(x), g(x)$, and $b(x)$

Let $x$ be a point on a 1-face. We discuss the details of computing $d_{\omega}(x), g(x)$, and $b(x)$.

Computing $d_{\omega}(x)$ for a Noncritical $\omega$ For any 1- or 2-face $\sigma$ containing $x$, we compute the $\omega$-deviation radius of $x$ with respect to $\sigma$ as follows.

Suppose that $\sigma$ is a 1-face. Let $E_{1}(z)=0$ and $E_{2}(z)=0$ be the equations of the two given surfaces whose intersection contains $\sigma$. For any point $z \in \operatorname{mani}(\sigma)$,
$\angle n_{\sigma}(x), n_{\sigma}(z)=\omega$ if and only if the angle between the tangents at $x$ and $z$ is $\omega$. Define $G(z)=\nabla E_{1}(z) \times \nabla E_{2}(z)$. We solve the following system for $z: E_{1}(z)=0$, $E_{2}(z)=0,\langle G(x), G(z)\rangle=\|G(x)\| \cdot\|G(z)\| \cdot \cos \omega$. Then, we return the distance between $x$ and the closest solution.

Suppose that $\sigma$ is a 2-face. Let $E_{\sigma}(z)=0$ be the equation of mani $(\sigma)$. Define $G_{\sigma}(z)=\left\langle\nabla E_{\sigma}(x), \nabla E_{\sigma}(z)\right\rangle /\left(\left\|\nabla E_{\sigma}(x)\right\| \cdot\left\|\nabla E_{\sigma}(z)\right\|\right)$. Then, $\sigma_{x, \omega}=\{z \in \operatorname{mani}(\sigma):$ $\left.\cos \left(\angle n_{\sigma}(x), n_{\sigma}(z)\right)=\cos \omega\right\}$ is described by the system $E_{\sigma}(z)=0, G_{\sigma}(z)=\cos \omega$. If $\nabla G_{\sigma}(z)$ is not parallel to $\nabla E_{\sigma}(z)$ for any point $z \in \sigma_{x, \omega}, \sigma_{x, \omega}$ is a collection of disjoint smooth closed curves by the implicit function theorem. If $\nabla G_{\sigma}(z)$ is parallel to $\nabla E_{\sigma}(z)$ for some point $z \in \sigma_{x, \omega}, \cos \omega$ is a critical value for the function $G_{\sigma}(z)$ restricted to mani $(\sigma)$. We can decide whether $\cos \omega$ and hence $\omega$ is critical by testing the solvability of the following system of equations: $E_{\sigma}(z)=0, G_{\sigma}(z)=$ $\cos \omega, \nabla G_{\sigma}(z) \times \nabla E_{\sigma}(z)=0$. If the system is solvable, $\omega$ is critical; otherwise, $\omega$ is not critical.

Suppose that $\omega$ is not critical. For each smooth closed curve in $\sigma_{x, \omega}$, its closest point to $x$ is a tangential contact point with $B(x, r)$ for some $r>0$. Each contact point $z$ is characterized by the fact that $x z$ is orthogonal to the tangent to $\sigma_{x, \omega}$ at $z$. Thus, it suffices to find all the tangential contact points and pick the one closest to $x$. The tangent at a point $z \in \sigma_{x, \omega}$ is parallel to $\nabla G_{\sigma}(z) \times \nabla E_{\sigma}(z)$. Thus, we solve the system $E_{\sigma}(z)=0, G_{\sigma}(z)=\cos \omega,\left\langle\nabla G_{\sigma}(z) \times \nabla E_{\sigma}(z),(x-z)\right\rangle=0$ and return the distance between $x$ and the closest solution.

The minimum distance returned over all faces containing $x$ is $d_{\omega}(x)$.

Perturbation The previous computation of $d_{\omega}(x)$ cannot be performed if $\omega$ is found critical with respect to some 2 -face $\sigma$ containing $x$. We can get around this problem by exploiting the strong version of the Sard's theorem [34].

Since $\operatorname{mani}(\sigma)$ is assumed to be $C^{3}$-smooth, the function $G_{\sigma}(z)=\left\langle\nabla E_{\sigma}(x)\right.$, $\left.\nabla E_{\sigma}(z)\right\rangle /\left(\left\|\nabla E_{\sigma}(x)\right\| \cdot\left\|\nabla E_{\sigma}(z)\right\|\right)$ is $C^{2}$-smooth. Under these conditions, the strong version of Sard's theorem states that the critical values of the restriction of $G_{\sigma}(z)$ to $\operatorname{mani}(\sigma)$ are isolated [34]. This allows us to perturb $\omega$ to a noncritical value slightly less than $\omega$. The details are as follows.

We set $\alpha$ to be a positive constant as small as we wish. We check as before whether $\omega-\alpha$ is critical for any 2 -face containing $x$. That is, for any 2 -face $\sigma$ containing $x$, we check whether the system $E_{\sigma}(z)=0, G_{\sigma}(z)=\cos (\omega-\alpha), \nabla G_{\sigma}(z) \times \nabla E_{\sigma}(z)=0$ is solvable. If $\omega-\alpha$ is not critical for any 2 -face containing $x$, we set $\bar{\omega}=\omega-\alpha$ and compute $d_{\bar{\omega}}(x)$. If $\omega-\alpha$ is critical for some 2 -face containing $x$, we halve $\alpha$ and test the criticality of $\omega-\alpha$ again. By the strong version of the Sard's theorem, we must eventually find a small enough $\alpha$ such that $\omega-\alpha$ is not critical for any 2 -face containing $x$.

Computing $g(x)$ The minimum distance between $x$ and other faces not containing $x$ is $g(x)$. The distances from $x$ to other vertices can easily be computed in linear time. For any 1- or 2-face $\sigma$ not containing $x$, we compute the distance between $x$ and int $\sigma$ as follows.

Suppose that $\sigma$ is a 1-face. Let $E_{1}(z)=0$ and $E_{2}(z)=0$ be the equations of the two given surfaces $\Sigma_{1}$ and $\Sigma_{2}$ whose intersection contains $\sigma$. Any ball centered at
$x$ is tangent to a curve in $\Sigma_{1} \cap \Sigma_{2}$ at a point $z$ if and only if $x z$ is orthogonal to the tangent to $\Sigma_{1} \cap \Sigma_{2}$ at $z$. We find all such contact points $z$ by solving the system $E_{1}(z)=0, E_{2}(z)=0,\left\langle\nabla E_{1}(z) \times \nabla E_{2}(z),(x-z)\right\rangle=0$. Then, we return the distance between $x$ and the closest contact point on $\sigma$.

Suppose that $\sigma$ is a 2-face. Let $E(z)=0$ be the equation of mani $(\sigma)$. Any ball centered at $x$ is tangent to $\operatorname{mani}(\sigma)$ at a point $z$ if and only if $x z$ is normal to mani $(\sigma)$. We find all such tangential contact points $z$ by solving the system $E(z)=0, \nabla E(z) \times$ $(x-z)=0$. Then, we return the distance between $x$ and the closest contact point on $\sigma$.

Computing $b(x)$ For any 1- or 2-face $\sigma$ containing $x$, we determine the largest value $b_{\sigma}(x)>0$ such that for any $r<b_{\sigma}(x), B(x, r) \cap \operatorname{mani}(\sigma)$ is a closed ball of dimension $\operatorname{dim}(\sigma)$. This computation is similar to the computation of $g(x)$. The only difference is that we now return the distance between $x$ and the closest contact point instead of the closest contact point on $\sigma$. Afterwards, $b(x)=\min _{x \in \sigma} b_{\sigma}(x)$.

## Appendix C: Proof of Lemma 3.1

In Sect. C. 1 we first prove some properties of the protecting balls constructed. Then, we use these properties to show in Sect. C. 2 that the protecting ball construction procedure terminates correctly. Lemma 3.1(i) is obvious by construction. Lemma 3.1(ii)(v) are proved in Sects. C.3-C.6.

Throughout this section we use $\sigma$ to denote the 1-face that we are processing. We use $u=x_{1}$ and $v$ to denote the endpoints of $\sigma$, and $\left(x_{2}, \ldots, x_{m-1}, y_{m}, x_{0}\right)$ to denote the protecting ball centers in int $\sigma$. The quantities $r_{k}$ and $r_{0 k}$ are defined as in Sect. 3. Although the value $m$ is used in Sect. C.1, the results in Sect. C. 1 hold independent of whether the protecting ball construction procedure terminates or not. If the procedure were not to terminate, $m$ would be equal to $\infty$.

We define the host of $x_{k}$ as follows. For $1 \leqslant k \leqslant m$, if $r_{k}=\lambda \mathrm{f}_{\omega_{j}}\left(x_{j}\right)+\lambda\left\|x_{j}-x_{k}\right\|$ for some $0 \leqslant j \leqslant k$, define $\operatorname{host}\left(x_{k}\right)=x_{k}$; otherwise, define $\operatorname{host}\left(x_{k}\right)=x_{b}$, where $b=\max \left\{i: i<k\right.$ and $\left.\operatorname{host}\left(x_{i}\right)=x_{i}\right\}$. Notice that $\operatorname{host}\left(x_{1}\right)=x_{1}, \operatorname{host}\left(x_{2}\right)=x_{2}$, and if $\operatorname{host}\left(x_{k}\right) \neq x_{k}, r_{k}=\left\|x_{k-1}-x_{k}\right\| / 2$.

## C. 1 Technical Lemmas

We know that if $\operatorname{host}\left(x_{k}\right) \neq x_{k}, r_{k}=\left\|x_{k-1}-x_{k}\right\| / 2$. The case of $\operatorname{host}\left(x_{k}\right)=x_{k}$ is discussed below.

Lemma C. $1 \forall 2 \leqslant k \leqslant m$, if $\operatorname{host}\left(x_{k}\right)=x_{k}, r_{k}=\min _{0 \leqslant j \leqslant k}\left\{\lambda \mathrm{f}_{\omega_{j}}\left(x_{j}\right)+\lambda\left\|x_{j}-x_{k}\right\|\right\}$.
Proof The lemma is true by construction for $k \geqslant 3$. It suffices to show that $\left\|x_{i}-x_{2}\right\| \geqslant \mathrm{f}_{\omega_{2}}\left(x_{2}\right)$ for $i \in\{0,1\}$ so that $\lambda \mathrm{f}_{\omega_{2}}\left(x_{2}\right)<\min _{0 \leqslant i \leqslant 1}\left\{\lambda \mathrm{f}_{\omega_{i}}\left(x_{i}\right)+\right.$ $\left.\lambda\left\|x_{i}-x_{2}\right\|\right\}$. It follows from definition that $\left\|x_{1}-x_{2}\right\|=\left\|u-x_{2}\right\| \geqslant \mathrm{f}_{\omega_{2}}\left(x_{2}\right)$. Observe that $\lambda\|u-v\| \geqslant \max \{\lambda g(u), \lambda g(v)\} \geqslant \max \left\{\lambda \mathrm{f}_{\omega_{u}}(u), \lambda \mathrm{f}_{\omega_{v}}(v)\right\}=\max \left\{\left\|u-x_{2}\right\|\right.$, $\left.\left\|v-x_{0}\right\|\right\}$. So $\left\|x_{0}-x_{2}\right\| \geqslant\|u-v\|-\left\|u-x_{2}\right\|-\left\|v-x_{0}\right\| \geqslant(1-2 \lambda)\|u-v\| \geqslant$
$(1-2 \lambda) \mathrm{f}_{\omega_{u}}(u)$. Since $\mathrm{f}_{\omega_{2}}\left(x_{2}\right) \leqslant\left\|u-x_{2}\right\|=\lambda \mathrm{f}_{\omega_{u}}(u),\left\|x_{0}-x_{2}\right\| \geqslant(1-2 \lambda) \mathrm{f}_{\omega_{2}}\left(x_{2}\right) / \lambda>$ $\mathrm{f}_{\omega_{2}}\left(x_{2}\right)$ as $\lambda \leqslant 0.01$.

We relate radius $\left(B_{x_{k}}\right)$ to radius $\left(B_{\operatorname{host}\left(x_{k}\right)}\right)$ and prove a bound on $\left\|x_{k}-\operatorname{host}\left(x_{k}\right)\right\|$.
Lemma C. $2 \forall 1 \leqslant k \leqslant m$, if $\operatorname{host}\left(x_{k}\right)=x_{b}, r_{k}=\left(\frac{3}{5}\right)^{k-b} r_{b}$ and $\left\|x_{b}-x_{k}\right\| \leqslant 3 r_{b}$.
Proof The lemma is trivial if $x_{b}=x_{k}$. Assume that $x_{b} \neq x_{k}$ and so $k \geqslant 3$. For $b<$ $i \leqslant k, r_{i}=\frac{1}{2}\left\|x_{i-1}-x_{i}\right\|$ as $\operatorname{host}\left(x_{i}\right) \neq x_{i}$. Because $r_{b+1}=\frac{1}{2}\left\|x_{b}-x_{b+1}\right\|=\frac{3}{5} r_{b}$, a simple induction shows that $r_{i}=\left(\frac{3}{5}\right)^{i-b} r_{b}$ for $b<i \leqslant k$. We have $\left\|x_{b}-x_{k}\right\| \leqslant$ $\sum_{i=b+1}^{k}\left\|x_{i-1}-x_{i}\right\| \leqslant 2 r_{b} \sum_{j=1}^{\infty}\left(\frac{3}{5}\right)^{j}=3 r_{b}$.

We show that the radii of protecting balls vary gradually along int $\sigma$.

## Lemma C. 3

(i) $\forall 2 \leqslant k \leqslant m, \forall 0 \leqslant j \leqslant k, r_{k} \leqslant r_{j}+\lambda\left\|x_{j}-x_{k}\right\|$.
(ii) $\forall 2 \leqslant k<m, r_{k}=\frac{5}{6}\left\|x_{k}-x_{k+1}\right\|$ and $r_{k+1} \leqslant \frac{5+6 \lambda}{6}\left\|x_{k}-x_{k+1}\right\|=\frac{5+6 \lambda}{5} r_{k}$.
(iii) $\forall 2 \leqslant k \leqslant m, r_{0 k} \geqslant r_{k}-\lambda\left\|x_{k}-x_{0}\right\|$.

Proof Consider (i). For $0 \leqslant j \leqslant k$, by definition, $r_{j} \geqslant \lambda \mathrm{f}_{\omega_{i_{j}}}\left(x_{i_{j}}\right)+\lambda\left\|x_{j}-x_{i_{j}}\right\|$ for some $i_{j} \leqslant j$. If $\operatorname{host}\left(x_{k}\right)=x_{k}$, by Lemma C.1, $r_{k} \leqslant \lambda \mathrm{f}_{\omega_{i_{j}}}\left(x_{i_{j}}\right)+\lambda\left\|x_{k}-x_{i_{j}}\right\| \leqslant$ $\lambda \mathrm{f}_{\omega_{i j}}\left(x_{i_{j}}\right)+\lambda\left\|x_{j}-x_{i_{j}}\right\|+\lambda\left\|x_{j}-x_{k}\right\| \leqslant r_{j}+\lambda\left\|x_{j}-x_{k}\right\|$. Suppose that host $\left(x_{k}\right)=$ $x_{b}$ for some $b<k$. For $b \leqslant j<k$, since $\operatorname{host}\left(x_{j}\right)=x_{b}$, Lemma C. 2 implies that $r_{k}=\left(\frac{3}{5}\right)^{k-b} r_{b}<\left(\frac{3}{5}\right)^{j-b} r_{b}=r_{j}$. For $0 \leqslant j<b, r_{j}+\lambda\left\|x_{j}-x_{k}\right\| \geqslant r_{j}+$ $\lambda\left\|x_{j}-x_{b}\right\|-\lambda\left\|x_{b}-x_{k}\right\|$. We have shown that $r_{b} \leqslant r_{j}+\lambda\left\|x_{j}-x_{b}\right\| \operatorname{as} \operatorname{host}\left(x_{b}\right)=x_{b}$. Also, $\left\|x_{b}-x_{k}\right\| \leqslant 3 r_{b}$ by Lemma C.2. Thus, $r_{j}+\lambda\left\|x_{j}-x_{k}\right\| \geqslant(1-3 \lambda) r_{b}=$ $(1-3 \lambda) 5^{k-b} r_{k} / 3^{k-b} \geqslant r_{k}$ as $\lambda \leqslant 0.01$. This proves (i). For $2 \leqslant k<m, r_{k}=$ $\frac{5}{6}\left\|x_{k}-x_{k+1}\right\|$ by construction, and by (i), $r_{k+1} \leqslant r_{k}+\lambda\left\|x_{k}-x_{k+1}\right\|$ $=\frac{5+6 \lambda}{6}\left\|x_{k}-x_{k+1}\right\|=\frac{5+6 \lambda}{5} r_{k}$. This proves (ii). By definition, there exists $0 \leqslant j \leqslant k$ such that $r_{0 k}=r_{j}+\lambda\left\|x_{j}-x_{0}\right\|$, so by (i), $r_{0 k} \geqslant r_{k}-\lambda\left\|x_{j}-x_{k}\right\|+\lambda\left\|x_{j}-x_{0}\right\| \geqslant$ $r_{k}-\lambda\left\|x_{k}-x_{0}\right\|$. This proves (iii).

## C. 2 Proof of Termination

The next lemma shows the correctness of our strategy of defining $x_{k}$ for $3 \leqslant k \leqslant m$.
Lemma C. 4 For $3 \leqslant k \leqslant m, B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right) \cap \sigma$ is an open curve, and $x_{k}$ is its only endpoint that satisfies $\angle x_{k-2} x_{k-1} x_{k}>\pi / 2$. Also, $x_{k}$ lies between $x_{k-1}$ and $v$ along $\sigma$.

Proof Let $x_{b}=\operatorname{host}\left(x_{k-2}\right)$. Choose any number $r$ from the range $\left(7 \lambda \mathrm{f}_{\omega_{b}}\left(x_{b}\right), \mathrm{f}_{\omega_{b}}\left(x_{b}\right)\right)$. By Lemma 2.5(ii)(b), $B\left(x_{b}, r\right) \cap \sigma$ is an open curve. Moreover, since $k \geqslant 3$, we have $x_{b} \in \operatorname{int} \sigma$. Then, as $\mathrm{f}_{\omega_{b}}\left(x_{b}\right) \leqslant g\left(x_{b}\right)$ by definition, the endpoints of $B\left(x_{b}, r\right) \cap \sigma$ lie on the boundary of $B\left(x_{b}, r\right)$.

We first show that $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right) \subset B\left(x_{b}, r\right)$. If $k=3, x_{b}=x_{1}$ and $\left\|x_{1}-x_{2}\right\|+$ $\frac{6}{5} r_{2} \leqslant r_{1}+\frac{6}{5} r_{1}<3 r_{1}=3 \lambda \mathrm{f}_{\omega_{1}}\left(x_{1}\right)<r$. If $k>3$, Lemma C. 2 and Lemma C.3(ii)
imply that $\left\|x_{b}-x_{k-2}\right\|+\frac{6}{5} r_{k-2}+\frac{6}{5} r_{k-1}<7 r_{b} \leqslant 7 \lambda \mathrm{f}_{\omega_{b}}\left(x_{b}\right)<r$. We conclude that $\left\|x_{b}-x_{k-1}\right\|+\frac{6}{5} r_{k-1}<r$, which implies that $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right) \subset B\left(x_{b}, r\right)$.

Next, we show that $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right) \cap \sigma$ is an open curve. Suppose not. Then, we can walk from $x_{k-1}$ along $B\left(x_{b}, r\right) \cap \sigma$ so that we leave $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right)$ at a point $y$ and reenter $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right)$ later. Thus, after leaving $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right)$ at $y$, we must return to another point $y^{\prime}$ on the plane $H$ tangent to $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right)$ at $y$. We can translate $H$ to a plane that is tangent to the subcurve between $y$ and $y^{\prime}$ at a point $z$. Notice that $x_{k-1} y \perp H$ which implies that $x_{k-1} y$ is parallel to $n_{\sigma}(z)$. But this is a contradiction because, by applying Lemma 2.5(ii)(a) and (iii) to $B\left(x_{b}, r\right) \cap \sigma$, we get $\angle n_{\sigma}(z), x_{k-1} y \geqslant \angle n_{\sigma}\left(x_{b}\right), x_{k-1} y-\angle n_{\sigma}\left(x_{b}\right), n_{\sigma}(z)>\pi / 2-2 \omega$.

Since $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right) \cap \sigma$ is an open curve, it has one endpoint $x_{k}$ between $x_{k-1}$ and $v$ and one endpoint $z^{\prime}$ between $u$ and $x_{k-1}$. We have $\angle x_{k-2} x_{k-1} x_{k} \geqslant$ $\angle n_{\sigma}\left(x_{k-1}\right), x_{k-1} x_{k-2}+\angle n_{\sigma}\left(x_{k-1}\right), x_{k-1} x_{k} \geqslant \angle n_{\sigma}\left(x_{b}\right), x_{k-1} x_{k-2}+\angle n_{\sigma}\left(x_{b}\right)$, $x_{k-1} x_{k}-2 \cdot \angle n_{\sigma}\left(x_{b}\right), n_{\sigma}\left(x_{k-1}\right)$. Thus, by Lemma 2.5(ii)(a) and (iii), we conclude that $\angle x_{k-1} x_{k-1} x_{k}>\pi-4 \omega$, which is greater than $\pi / 2$. On the other hand, $\angle x_{k-2} x_{k-1} z^{\prime} \leqslant \pi-\angle n_{\sigma}\left(x_{k-1}\right), x_{k-1} x_{k-2}-\angle n_{\sigma}\left(x_{k-1}\right), x_{k-1} z^{\prime} \leqslant \pi-\angle n_{\sigma}\left(x_{b}\right)$, $x_{k-1} x_{k-2}-\angle n_{\sigma}\left(x_{b}\right), x_{k-1} z^{\prime}+2 \cdot \angle n_{\sigma}\left(x_{b}\right), n_{\sigma}\left(x_{k-1}\right)<4 \omega$, which is less than $\pi / 2$.

We prove in Lemma C. 5 below that the protecting ball construction procedure terminates correctly. Properties (i)-(iii) will be needed in some subsequent proofs.

## Lemma C. 5

(i) $\frac{2}{1+\lambda} r_{m-1}<\left\|x_{m-1}-x_{0}\right\|<5 r_{m-1}$.
(ii) $\max \left\{\left\|x_{m-1}-y_{m}\right\|,\left\|y_{m}-x_{0}\right\|\right\}<\min \left\{4 r_{0 m-1}, 5 r_{m-1}\right\}$.
(iii) $0.09 r_{m-1} \leqslant 0.1 r_{0 m-1} \leqslant \operatorname{radius}\left(B_{y_{m}}\right)<\min \left\{5 \lambda g\left(y_{m}\right), 4 r_{0 m-1}, 5 r_{m-1}\right\}$.
(iv) The protecting ball construction procedure terminates correctly.

Proof We claim that $B_{x_{2}} \cap B\left(x_{0}, r_{0}\right)=\emptyset$. By Lemma 2.5(i), $r_{0}=\lambda \mathrm{f}_{\omega_{0}}\left(x_{0}\right) \leqslant$ $\lambda g\left(x_{0}\right) \leqslant \lambda\left\|v-x_{0}\right\|$. Similarly, $r_{2} \leqslant \lambda\left\|u-x_{2}\right\|$ and $\lambda\|u-v\| \geqslant \max \{\lambda g(u), \lambda g(v)\} \geqslant$ $\max \left\{\lambda \mathrm{f}_{\omega_{u}}(u), \lambda \mathrm{f}_{\omega_{v}}(v)\right\}=\max \left\{\left\|u-x_{2}\right\|,\left\|v-x_{0}\right\|\right\}$. Thus, $\left\|u-x_{2}\right\|+r_{2}+r_{0}+$ $\left\|v-x_{0}\right\| \leqslant 2 \lambda(1+\lambda)\|u-v\|<\|u-v\|$. This implies our claim.

Since $r_{02} \leqslant r_{0}$, by our claim, the protecting ball construction starts with the right condition that $B_{x_{2}} \cap B\left(x_{0}, r_{02}\right)=\emptyset$. By Lemma C.4, our procedure correctly defines $x_{k}$ for $3 \leqslant k \leqslant m$. For $2 \leqslant k<m$, since $B_{x_{k}} \cap B\left(x_{0}, r_{0 k}\right)=\emptyset,\left\|x_{k}-x_{0}\right\|>r_{k}+r_{0 k} \geqslant$ $2 r_{k}-\lambda\left\|x_{k}-x_{0}\right\|$ by Lemma C.3(iii). Thus, $\left\|x_{k}-x_{0}\right\|>\frac{2}{1+\lambda} r_{k}>\frac{6}{5} r_{k}$. It follows that the protecting ball construction procedure never advances beyond $x_{0}$. This also proves the first inequality in (i) by substituting $k=m-1$. For $k \geqslant 3$, both the distance advanced along $\sigma$ by $B_{x_{k}}$ and $r_{0 k}$ are bounded away from zero. Thus, we must eventually place the ball $B\left(x_{m}, r_{m}\right)$ that overlaps with $B\left(x_{0}, r_{0 m}\right)$.

We claim that

$$
\begin{equation*}
\left\|x_{m-1}-x_{0}\right\|<4 r_{0 m-1} \leqslant 4 r_{0} . \tag{2}
\end{equation*}
$$

By Lemma C.3(iii), $r_{m-1} \leqslant r_{0 m-1}+\lambda\left\|x_{m-1}-x_{0}\right\|$. Then, by Lemma C.3(i) and (ii), $r_{m} \leqslant r_{m-1}+\lambda\left\|x_{m-1}-x_{m}\right\|=\frac{5+6 \lambda}{5} r_{m-1} \leqslant \frac{5+6 \lambda}{5} r_{0 m-1}+\frac{5 \lambda+6 \lambda^{2}}{5}\left\|x_{m-1}-x_{0}\right\|$. Substituting these inequalities into $\left\|x_{m-1}-x_{0}\right\| \leqslant \frac{6}{5} r_{m-1}+r_{m}+r_{0 m}$ (recall that
$B\left(x_{m}, r_{m}\right)$ overlaps with $B\left(x_{0}, r_{0 m}\right)$ ), we get $\left\|x_{m-1}-x_{0}\right\| \leqslant \frac{11+6 \lambda}{5} r_{0 m-1}+r_{0 m}+$ $\frac{11 \lambda+6 \lambda^{2}}{5}\left\|x_{m-1}-x_{0}\right\|$. Since $r_{0 m} \leqslant r_{0 m-1}$, we get $\left\|x_{m-1}-x_{0}\right\| \leqslant \frac{16+6 \lambda}{5} r_{0 m-1}+$ $\frac{11 \lambda+6 \lambda^{2}}{5}\left\|x_{m-1}-x_{0}\right\| \Rightarrow\left\|x_{m-1}-x_{0}\right\| \leqslant \frac{16+6 \lambda}{5-11 \lambda-6 \lambda^{2}} r_{0 m-1}<4 r_{0 m-1} \leqslant 4 r_{0}$. This proves (2).

By (2) and the definition of $r_{0 m-1},\left\|x_{m-1}-x_{0}\right\|<4 r_{0 m-1} \leqslant 4 r_{m-1}+$ $4 \lambda\left\|x_{m-1}-x_{0}\right\| \Rightarrow\left\|x_{m-1}-x_{0}\right\|<\frac{4}{1-4 \lambda} r_{m-1}<5 r_{m-1}$. This proves the second inequality in (i).

Since $4 r_{0}=4 \lambda \mathrm{f}_{\omega_{0}}\left(x_{0}\right)<\mathrm{f}_{\omega_{0}}\left(x_{0}\right)$, by Lemma 2.5(ii), $B\left(x_{0}, 4 r_{0}\right) \cap \sigma$ is an open curve, and for any point $y \in B\left(x_{0}, 4 r_{0}\right) \cap \sigma, \angle n_{\sigma}\left(x_{0}\right), n_{\sigma}(y)<\omega$. By Lemma 2.5(iii), $\angle n_{\sigma}\left(x_{0}\right), x_{0} x_{m-1}>\pi / 2-\omega$, which implies that $n_{\sigma}\left(x_{0}\right)$ makes an angle less than $\omega$ with the bisector plane of $B_{x_{0}}$ and $B_{x_{m-1}}$. It follows that $B\left(x_{0}, 4 r_{0}\right) \cap \sigma$ contains the subcurve between $x_{m-1}$ and $x_{0}$, which intersects the bisector plane of $B_{x_{m-1}}$ and $B_{x_{0}}$ exactly once. This intersection point is $y_{m}$ and $\left\|y_{m}-x_{0}\right\| \leqslant 4 r_{0}$. This proves that the procedure terminates correctly, i.e., (iv) is true.

Since $B\left(x_{0}, 4 r_{0}\right) \cap \sigma$ contains the subcurve between $x_{m-1}$ and $x_{0}$, by Lemma 2.5(ii)(a) and (iii), $\angle x_{m-1} y_{m} x_{0} \geqslant \angle n_{\sigma}\left(y_{m}\right), y_{m} x_{m-1}+\angle n_{\sigma}\left(y_{m}\right), y_{m} x_{0}>$ $\angle n_{\sigma}\left(x_{0}\right), y_{m} x_{m-1}+\angle n_{\sigma}\left(x_{0}\right), y_{m} x_{0}-2 \cdot \angle n_{\sigma}\left(x_{0}\right), n_{\sigma}\left(y_{m}\right)>\pi-4 \omega>\pi / 2$. Thus, $\max \left\{\left\|x_{m-1}-y_{m}\right\|,\left\|y_{m}-x_{0}\right\|\right\}<\left\|x_{m-1}-x_{0}\right\|$. Then (ii) follows from (i) and (2).

Since $B_{x_{m-1}} \cap B\left(x_{0}, r_{0 m-1}\right)=\emptyset$ and radius $\left(B_{x_{0}}\right)=\frac{4}{5} r_{0 m-1}$, the distance between $B_{x_{m-1}}$ and $B_{x_{0}}$ is at least $\frac{1}{5} r_{0 m-1}$. Because $B_{y_{m}}$ covers the gap between $B_{x_{m-1}}$ and $B_{x_{0}}$, we get $\operatorname{radius}\left(B_{y_{m}}\right) \geqslant 0.1 r_{0 m-1}$. By (i) and Lemma C.3(iii), $r_{0 m-1} \geqslant r_{m-1}-$ $\lambda\left\|x_{m-1}-x_{0}\right\| \geqslant r_{m-1}-5 \lambda r_{m-1} \geqslant 0.9 r_{m-1}$. Thus, radius $\left(B_{y_{m}}\right) \geqslant 0.1 r_{0 m-1} \geqslant$ $0.09 r_{m-1}$. This proves the first two inequalities in (iii).

Since $x_{0}$ lies outside $B_{y_{m}}$, by (ii), radius $\left(B_{y_{m}}\right)<\left\|y_{m}-x_{0}\right\|<\min \left\{4 r_{0 m-1}, 5 r_{m-1}\right\}$. This proves part of the third inequality in (iii). Starting with $\left\|y_{m}-x_{0}\right\|<4 r_{0 m-1} \leqslant$ $4 r_{0}$, we get $\left\|y_{m}-x_{0}\right\|<4 r_{0}=4 \lambda \mathrm{f}_{\omega_{0}}\left(x_{0}\right) \leqslant 4 \lambda g\left(x_{0}\right)$. Since $g$ is 1-Lipschitz over int $\sigma$ by Lemma 2.2, $\left\|y_{m}-x_{0}\right\|<4 \lambda g\left(y_{m}\right)+4 \lambda\left\|y_{m}-x_{0}\right\| \Rightarrow \operatorname{radius}\left(B_{y_{m}}\right)<\left\|y_{m}-x_{0}\right\|<$ $\frac{4 \lambda}{1-4 \lambda} g\left(y_{m}\right)<5 \lambda g\left(y_{m}\right)$.

## C. 3 Lemma 3.1(ii)

The next result implies that $u=x_{1}$ does not influence the setting of $r_{k}$ for $3 \leqslant k<m$ and $r_{0 m-1}$.

Lemma C. $6 \forall 3 \leqslant k<m, \lambda \mathrm{f}_{\omega_{1}}\left(x_{1}\right)+\lambda\left\|x_{1}-x_{k}\right\|>\lambda \mathrm{f}_{\omega_{2}}\left(x_{2}\right)+\lambda\left\|x_{2}-x_{k}\right\|$ and $r_{1}+\lambda\left\|x_{1}-x_{0}\right\|>r_{2}+\lambda\left\|x_{2}-x_{0}\right\|$.

Proof Because $\lambda \leqslant 0.01$ and $\mathrm{f}_{\omega_{2}}\left(x_{2}\right) \leqslant\left\|x_{1}-x_{2}\right\|, \mathrm{f}_{\omega_{1}}\left(x_{1}\right)=\frac{1}{\lambda}\left\|x_{1}-x_{2}\right\|>$ $\mathrm{f}_{\omega_{2}}\left(x_{2}\right)+\left\|x_{1}-x_{2}\right\|$. It follows immediately that $\lambda \mathrm{f}_{\omega_{1}}\left(x_{1}\right)+\lambda\left\|x_{1}-x_{k}\right\|>\lambda \mathrm{f}_{\omega_{2}}\left(x_{2}\right)+$ $\lambda\left\|x_{2}-x_{k}\right\|$ and $r_{1}+\lambda\left\|x_{1}-x_{0}\right\|=\lambda \mathrm{f}_{\omega_{1}}\left(x_{1}\right)+\lambda\left\|x_{1}-x_{0}\right\|>\lambda \mathrm{f}_{\omega_{2}}\left(x_{2}\right)+\lambda\left\|x_{1}-x_{2}\right\|+$ $\lambda\left\|x_{1}-x_{0}\right\| \geqslant r_{2}+\lambda\left\|x_{2}-x_{0}\right\|$.

We are ready to prove Lemma 3.1(ii).

Proof of Lemma 3.1(ii) For any $p \in\left\{u, x_{2}, v\right\}$, since radius $\left(B_{p}\right)=\lambda \mathrm{f}_{\bar{\omega}}(p)$, where $\bar{\omega}=\omega_{u}, \omega_{2}$ or $\omega_{v}$ depending on the identity of $p$, by Lemma $2.5(\mathrm{i})$, radius $\left(() \mathcal{B}_{p}\right) \in$ $\left[\frac{1}{2} \lambda \bar{\omega} f(p), \lambda g(p)\right] \subseteq\left[\frac{99}{200} \lambda \omega f(p), \lambda g(p)\right]$ because $\bar{\omega} \in[0.99 \omega, \omega]$.

Consider $B_{x_{k}}$ for any $3 \leqslant k<m$. By definition, there exists $0 \leqslant j \leqslant k$ such that $r_{k} \geqslant \lambda \mathrm{f}_{\omega_{j}}\left(x_{j}\right)+\lambda\left\|x_{j}-x_{k}\right\|$, which is at least $\frac{1}{2} \lambda \omega_{j} f\left(x_{j}\right)+\lambda\left\|x_{j}-x_{k}\right\| \geqslant$ $\frac{99}{200} \lambda \omega f\left(x_{j}\right)+\lambda\left\|x_{j}-x_{k}\right\|$ by Lemma $2.5(\mathrm{i})$ and the fact that $\omega_{j} \geqslant 0.99 \omega$. We can choose $j>1$ by Lemma C. 6 and so $x_{j}, x_{k} \in \operatorname{int} \sigma$. Because $f$ is 1 -Lipschitz over int $\sigma$ by Lemma 2.2, $r_{k} \geqslant \frac{99}{200} \lambda \omega f\left(x_{j}\right)+\lambda\left\|x_{j}-x_{k}\right\|>\frac{99}{200} \lambda \omega f\left(x_{k}\right)$. This proves the lower bound. Let $x_{b}=\operatorname{host}\left(x_{k}\right)$. Since $k \geqslant 3, b \geqslant 2$ and so $x_{b}, x_{k} \in \operatorname{int} \sigma$. By Lemma C. 2 and Lemma 2.5(i), $r_{k}=\left(\frac{3}{5}\right)^{k-b} r_{b} \leqslant\left(\frac{3}{5}\right)^{k-b} \lambda \mathrm{f}_{\omega_{b}}\left(x_{b}\right) \leqslant\left(\frac{3}{5}\right)^{k-b} \lambda g\left(x_{b}\right)$. Since $g$ is 1-Lipschitz over int $\sigma$ by Lemma 2.2, $r_{k} \leqslant\left(\frac{3}{5}\right)^{k-b} \lambda g\left(x_{k}\right)+\left(\frac{3}{5}\right)^{k-b} \times$ $\lambda\left\|x_{b}-x_{k}\right\|$. By Lemma C. $2,\left(\frac{3}{5}\right)^{k-b} \lambda\left\|x_{b}-x_{k}\right\| \leqslant\left(\frac{3}{5}\right)^{k-b} 3 \lambda r_{b}=3 \lambda r_{k}$. This yields $r_{k} \leqslant\left(\frac{3}{5}\right)^{k-b} \frac{\lambda}{1-3 \lambda} g\left(x_{k}\right)<2 \lambda g\left(x_{k}\right)$ as $\lambda \leqslant 0.01$.

Consider $B_{x_{0}}$. We have radius $\left(B_{x_{0}}\right)=0.8 r_{0 m-1} \leqslant 0.8 r_{0}=0.8 \lambda \mathrm{f}_{\omega_{0}}\left(x_{0}\right) \leqslant$ $0.8 \lambda g\left(x_{0}\right)$. By definition and Lemma C.6, $r_{0 m-1}=r_{j}+\lambda\left\|x_{j}-x_{0}\right\|$ for some $j \leqslant m-1$ and $x_{j} \in$ int $\sigma$. We already know that $r_{j} \geqslant \frac{99}{200} \lambda \omega f\left(x_{j}\right)$. So $0.8 r_{0 m-1} \geqslant$ $0.8 \cdot\left(\frac{99}{200} \lambda \omega f\left(x_{j}\right)+\lambda\left\|x_{j}-x_{0}\right\|\right)>0.8 \cdot \frac{99}{200} \lambda \omega f\left(x_{0}\right)=\frac{99}{250} \lambda \omega f\left(x_{0}\right)$ because $f$ is 1-Lipschitz over int $\sigma$.

Consider $B_{y_{m}}$. By Lemma C.5(iii), radius $\left(B_{y_{m}}\right)<5 \lambda g\left(y_{m}\right)$. By Lemma C.5(ii), $f\left(y_{m}\right) \leqslant f\left(x_{0}\right)+\left\|y_{m}-x_{0}\right\|<f\left(x_{0}\right)+4 r_{0 m-1}$. We have shown in the previous paragraph* that $0.8 r_{0 m-1}>0.8 \cdot \frac{99}{200} \lambda \omega f\left(x_{0}\right)$. So $f\left(y_{m}\right)<\frac{200}{99 \lambda \omega} r_{0 m-1}+4 r_{0 m-1}=$ $\frac{200+396 \lambda \omega}{99 \lambda \omega} r_{0 m-1}$. Then, Lemma C.5(iii) implies that radius $\left(B_{y_{m}}\right) \geqslant 0.1 r_{0 m-1}>$ $\frac{99 \lambda \omega}{10(200+396 \lambda \omega)} f\left(y_{m}\right)>\frac{\lambda \omega}{21} f\left(y_{m}\right)$ as $\lambda \leqslant 0.01$ and $\omega \leqslant 0.01$.

## C. 4 Lemma 3.1(iii)

The next lemma shows that a ball $B(p, r)$ satisfies Lemma 3.1(iii) assuming that certain conditions are satisfied.

Lemma C. 7 Let $p$ and $p^{\prime}$ be two points point on the 1-face $\sigma$. Let $r^{\prime}<\mathrm{f}_{\omega}\left(p^{\prime}\right)$. Let $E$ be the set consisting of $\sigma$ and the 2-faces incident to $\sigma$. For any $r<g(p)$ such that $B(p, r) \subset B\left(p^{\prime}, \frac{1}{3} r^{\prime}\right)$, the following results hold.
(i) For any $\tau \in E$ and for any point $z \in B(p, r) \cap \operatorname{mani}(\tau), \angle n_{\tau}(p), n_{\tau}(z)<2 \omega$.
(ii) For any $\tau \in E, B(p, r) \cap \operatorname{mani}(\tau)$ and $B(p, r) \cap \tau$ are closed balls of dimension $\operatorname{dim}(\tau)$.

Proof Since $r^{\prime}<\mathrm{f}_{\omega}\left(p^{\prime}\right)$ and $B(p, r) \subset B\left(p^{\prime}, \frac{1}{3} r^{\prime}\right)$, for any point $z \in B(p, r) \cap$ $\operatorname{mani}(\tau), \angle n_{\tau}(p), n_{\tau}(z) \leqslant \angle n_{\tau}\left(p^{\prime}\right), n_{\tau}(p)+\angle n_{\tau}\left(p^{\prime}\right), n_{\tau}(z)<2 \omega$ by Lemma 2.5(ii)(a). This proves (i).

Take any $\tau \in E$. Assume to the contrary that $B(p, r) \cap \operatorname{mani}(\tau)$ is not a closed ball of dimension $\operatorname{dim}(\tau)$. Then, there exists a concentric ball $B \subset B(p, r)$ such that $B$ is tangent to $B(p, r) \cap \operatorname{mani}(\tau)$ at a point $q$. We have $\angle n_{\tau}(p), p q \leqslant$ $\angle n_{\tau}(p), n_{\tau}(q)<2 \omega$ by (i). (Note that $\angle n_{\tau}(p), p q=\angle n_{\tau}(p), n_{\tau}(q)$ if $\tau$ is a 2face and $\angle n_{\sigma}(p), p q \leqslant \angle n_{\sigma}(p), n_{\sigma}(q)$.) However, as $p, q \in B\left(p^{\prime}, \frac{1}{3} r^{\prime}\right) \cap \operatorname{mani}(\tau)$
and $r^{\prime}<\mathrm{f}_{\omega}\left(p^{\prime}\right)$, by Lemma 2.5(ii)(a), (iii), and (iv), $\angle n_{\tau}(p), p q \geqslant \angle n_{\tau}\left(p^{\prime}\right), p q-$ $\angle n_{\tau}\left(p^{\prime}\right), n_{\tau}(p)>\pi / 2-2 \omega$, a contradiction.

Because $B(p, r) \cap \operatorname{mani}(\tau)$ is a closed ball and $r<g(p)$ by assumption, we can invoke Lemma 1.1 to conclude that $B(p, r) \cap \tau$ is a closed ball of dimension $\operatorname{dim}(\tau)$.

The next two lemmas show that the conditions of Lemma C. 7 can be satisfied for $y_{m}$ and $x_{k}$ for $3 \leqslant k<m$.

Lemma C. 8 Let $r \leqslant 20 \cdot \operatorname{radius}\left(B_{y_{m}}\right)$. Let $r^{\prime}=0.9 \mathrm{f}_{\omega_{v}}(v)$. Then $r<g\left(y_{m}\right)$ and $B\left(y_{m}, r\right) \subset B\left(v, \frac{1}{3} r^{\prime}\right)$. Hence, $B\left(y_{m}, r\right)$ and $B\left(v, r^{\prime}\right)$ satisfy the conditions of Lemma C.7.

Proof It follows from Lemma C.5(iii) that $r<g\left(y_{m}\right): r \leqslant 20 \operatorname{radius}\left(B_{y_{m}}\right)<$ $100 \lambda g\left(y_{m}\right) \leqslant g\left(y_{m}\right)$ as $\lambda \leqslant 0.01$. We have

$$
\begin{equation*}
r_{0 m-1} \leqslant r_{0}=\lambda \mathrm{f}_{\omega_{0}}\left(x_{0}\right) \leqslant \lambda\left\|x_{0}-v\right\|=\lambda^{2} \mathrm{f}_{\omega_{v}}(v) . \tag{3}
\end{equation*}
$$

By Lemma C.5(iii) and (3), $r \leqslant 20$ radius $\left(B_{y_{m}}\right)<80 r_{0 m-1} \leqslant 80 \lambda^{2} \mathrm{f}_{\omega_{v}}(v)$. We have $\left\|y_{m}-v\right\| \leqslant\left\|x_{0}-v\right\|+\left\|y_{m}-x_{0}\right\|=\lambda \mathrm{f}_{\omega_{v}}(v)+\left\|y_{m}-x_{0}\right\|$, which is less than $(\lambda+$ $\left.4 \lambda^{2}\right) \mathrm{f}_{\omega_{v}}(v)$ by Lemma C.5(ii) and (3). Therefore, $\left\|y_{m}-v\right\|+r<\left(\lambda+84 \lambda^{2}\right) \mathrm{f}_{\omega_{v}}(v)<$ $0.3 \mathrm{f}_{\omega_{v}}(v)=r^{\prime} / 3$ as $\lambda \leqslant 0.01$. So $B\left(y_{m}, r\right) \subset B\left(v, \frac{1}{3} r^{\prime}\right)$.

Lemma C. 9 Let $3 \leqslant k<m$. Let $x_{b}=\operatorname{host}\left(x_{k}\right)$. Let $r \leqslant 20 \cdot \operatorname{radius}\left(B_{x_{k}}\right)$. Let $r^{\prime}=$ $0.9 \mathrm{f}_{\omega_{b}}\left(x_{b}\right)$. Then $r<g\left(x_{k}\right)$ and $B\left(x_{k}, r\right) \subset B\left(x_{b}, \frac{1}{3} r^{\prime}\right)$. Hence, $B\left(x_{k}, r\right)$ and $B\left(x_{b}, r^{\prime}\right)$ satisfy the conditions of Lemma C.7.

Proof Recall that $r_{k}=\operatorname{radius}\left(B_{x_{k}}\right)$ for $3 \leqslant k<m$. By Lemma 3.1(ii), $r \leqslant 20 r_{k}<$ $100 \lambda g\left(x_{k}\right) \leqslant g\left(x_{k}\right)$ as $\lambda \leqslant 0.01$. We have $\left\|x_{b}-x_{k}\right\|+r \leqslant\left\|x_{b}-x_{k}\right\|+20 r_{k}$, which is at most $3 r_{b}+20 r_{b}=23 r_{b}$ by Lemma C.2. Since $23 r_{b} \leqslant 23 \lambda \mathrm{f}_{\omega_{b}}\left(x_{b}\right)<0.3 \mathrm{f}_{\omega_{b}}\left(x_{b}\right)$ as $\lambda \leqslant 0.01$, we conclude that $B\left(x_{k}, r\right) \subset B\left(x_{b}, 0.3 \mathrm{f}_{\omega_{b}}\left(x_{b}\right)\right)=B\left(x_{b}, \frac{1}{3} r^{\prime}\right)$.

We are ready to prove Lemma 3.1(iii).
Proof of Lemma 3.1(iii) Take any $p \in\left\{u, x_{0}, x_{2}, v\right\}$. For any $c \leqslant 20$, since $c$. radius $\left(B_{p}\right) \leqslant c \lambda \mathrm{f}_{\omega}(p)<\mathrm{f}_{\omega}(p)$, Lemma 2.5(ii) implies that Lemma 3.1(iii) holds for $p$. By Lemma C. 8 and Lemma C.7, Lemma 3.1(iii) holds for $y_{m}$. Similarly, by Lemma C. 9 and Lemma C.7, Lemma 3.1(iii) holds for $x_{k}$ for $3 \leqslant k<m$.

## C. 5 Lemma 3.1(iv)

## C.5.1 Proof of Lemma 3.1(iv)(a)

By construction, $x_{0}$ and $x_{2}$ lie on the boundaries of $B_{v}$ and $B_{u}$, respectively. Since $\operatorname{radius}\left(B_{x_{0}}\right) \leqslant r_{0}=\lambda \mathrm{f}_{\omega_{0}}\left(x_{0}\right)<g\left(x_{0}\right) \leqslant\left\|x_{0}-v\right\|, v$ lies outside $B_{x_{0}}$. Similarly, $u$ lies outside $B_{x_{2}}$.

For $3 \leqslant k<m, x_{k}$ lies on the boundary of $B\left(x_{k-1}, \frac{6}{5} r_{k-1}\right)$ and hence outside $B_{x_{k-1}}$. By Lemma C.3(ii), for $3 \leqslant k<m,\left\|x_{k-1}-x_{k}\right\| \geqslant \frac{6}{5+6 \lambda} r_{k}>r_{k}$ as $\lambda \leqslant 0.01$. So $x_{k-1}$ lies outside $B_{x_{k}}$.

Since $B_{x_{m-1}} \cap B_{x_{0}}=\emptyset$, they do not intersect their bisector plane. It follows that $y_{m}$ lies outside $B_{x_{m-1}}$ and $B_{x_{0}}$. Since $B_{y_{m}}$ is orthogonal to $B_{x_{m-1}}$ and $B_{x_{0}}, x_{m-1}$ and $x_{0}$ lie outside $B_{y_{m}}$.

## C.5.2 Proof of Lemma 3.1(iv)(b) and Lemma 3.1(iv)(c)

We first show two lemmas.

Lemma C. 10 Let $B(a, r)$ and $B\left(a^{\prime}, r^{\prime}\right)$ be two protecting balls such that $a, a^{\prime} \in \sigma$ and $B\left(a^{\prime}, r^{\prime}\right) \subset B(a, 4 r)$. Let $\sigma\left(a, a^{\prime}\right)$ denote the subcurve between $a$ and $a^{\prime}$. For any point $z \in \sigma\left(a, a^{\prime}\right), \angle z a a^{\prime}<4 \omega$ and $\angle z a^{\prime} a<8 \omega$.

Proof Note that $B(a, 4 r) \cap \sigma$ is an open curve by Lemma 3.1(iii)(b). As $a^{\prime} \in B(a, 4 r)$ by assumption, it follows that $\sigma\left(a, a^{\prime}\right) \subset B(a, 4 r) \cap \sigma$. We apply Lemma 3.1(iii) and then Lemma 1.3(i) to $B(a, 4 r) \cap \sigma$. This allows us to conclude that:

$$
\begin{gather*}
\angle n_{\sigma}(a), a a^{\prime}>\pi / 2-2 \omega,  \tag{4}\\
\forall z \in \sigma\left(a, a^{\prime}\right), \quad \angle n_{\sigma}(a), a z>\pi / 2-2 \omega,  \tag{5}\\
\angle n_{\sigma}\left(a^{\prime}\right), a a^{\prime} \geqslant \angle n_{\sigma}(a), a a^{\prime}-\angle n_{\sigma}(a), n_{\sigma}\left(a^{\prime}\right)>\pi / 2-4 \omega,  \tag{6}\\
\forall z \in \sigma\left(a, a^{\prime}\right), \quad \angle n_{\sigma}\left(a^{\prime}\right), a^{\prime} z \geqslant \angle n_{\sigma}(a), a^{\prime} z-\angle n_{\sigma}(a), n_{\sigma}\left(a^{\prime}\right)>\pi / 2-4 \omega . \tag{7}
\end{gather*}
$$

For any point $z \in \sigma\left(a, a^{\prime}\right)$, (4) and (5) imply that $\angle z a a^{\prime}<4 \omega$; (6) and (7) imply that $\angle z a^{\prime} a<8 \omega$.

Lemma C. 11 Let $B(a, r)$ and $B\left(a^{\prime}, r^{\prime}\right)$ be two consecutive protecting balls such that $a, a^{\prime} \in \operatorname{int} \sigma$ and $r \geqslant r^{\prime}$. For any point $b$ on the circle $\operatorname{bd} B(a, r) \cap \operatorname{bd} B\left(a^{\prime}, r^{\prime}\right)$, $\angle b a a^{\prime} \geqslant \arctan (0.09)>8 \omega$.

Proof Consider the pairs of adjacent weighted points $\left\{\left(x_{k}, x_{k+1}\right): 2 \leqslant k \leqslant m-2\right\}$. We have $\left\|a-a^{\prime}\right\|=\left\|x_{k}-x_{k+1}\right\|=\frac{6}{5} r_{k}$. By construction, $r_{k+1} \geqslant \frac{1}{2}\left\|x_{k}-x_{k+1}\right\|=$ $\frac{3}{5} r_{k}$. By Lemma C.3(ii), $r_{k+1} \leqslant \frac{5+6 \lambda}{5} r_{k}<\frac{6}{5} r_{k}=\left\|a-a^{\prime}\right\|$. This implies that

$$
\begin{gather*}
r^{\prime} \geqslant 3 r / 5,  \tag{8}\\
\left\|a-a^{\prime}\right\| \leqslant 6 r / 5 . \tag{9}
\end{gather*}
$$

Drop a perpendicular from $b$ to the point $b^{\prime}$ on $a a^{\prime}$. If $\angle b a^{\prime} a \geqslant \pi / 4$, by (8), $\left\|b-b^{\prime}\right\|=r^{\prime} \sin \angle b a^{\prime} a \geqslant 3 r /(5 \sqrt{2})$, which implies that $\angle b a a^{\prime}=$ $\arcsin \left(\left\|b-b^{\prime}\right\| / r\right) \geqslant \arcsin (3 /(5 \sqrt{2}))>\arctan (0.09)$. If $\angle b a^{\prime} a<\pi / 4,\left\|a-b^{\prime}\right\|=$ $\left\|a-a^{\prime}\right\|-r^{\prime} \cos \angle b a^{\prime} a$. So by (8) and (9), $\left\|a-b^{\prime}\right\| \leqslant 6 r / 5-3 r /(5 \sqrt{2})<0.8 r$. Thus, $\angle b a a^{\prime}=\arccos \left(\left\|a-b^{\prime}\right\| / r\right)>\arccos (0.8)>\arctan (0.09)$.

Consider the pair $\left(x_{m-1}, y_{m}\right)$. By construction, radius $\left(B_{x_{m-1}}\right)=r_{m-1}$. By Lemma C.5(iii), $0.09 r_{m-1} \leqslant \operatorname{radius}\left(B_{y_{m}}\right)<5 r_{m-1}$. This implies that $r^{\prime} \geqslant 0.09 r$. Since $B_{x_{m-1}}$ and $B_{y_{m}}$ are orthogonal, $\angle a b a^{\prime}=\pi / 2$. So $\angle b a a^{\prime}=$ break $\arctan \left(r^{\prime} / r\right) \geqslant$ $\arctan (0.09)$.

Consider the pair $\left(y_{m}, x_{0}\right)$. By construction, radius $\left(B_{x_{0}}\right)=0.8 r_{0 m-1}$. By Lemma C.5(iii), $0.1 r_{0 m-1} \leqslant \operatorname{radius}\left(B_{y_{m}}\right)<4 r_{0 m-1}$. This implies that $r^{\prime} \geqslant 0.125 r$. Since $B_{y_{m}}$ and $B_{x_{0}}$ are orthogonal, $\angle a b a^{\prime}=\pi / 2$. So $\angle b a a^{\prime}=\arctan \left(r^{\prime} / r\right) \geqslant$ $\arctan (0.125)$.

Proof of Lemma 3.1(iv)(b) Let $B_{p}$ and $B_{q}$ be two consecutive protecting balls. Assume that $\operatorname{radius}\left(B_{p}\right) \geqslant \operatorname{radius}\left(B_{q}\right)$. Take any point $b$ on the circle $\mathrm{bd} B_{p} \cap \mathrm{bd} B_{q}$. We have $\angle b q p \geqslant \angle b p q$ as $\operatorname{radius}\left(B_{p}\right) \geqslant \operatorname{radius}\left(B_{q}\right)$. If $p, q \in \operatorname{int} \sigma, \angle b p q \geqslant$ $\arctan (0.09)$ by Lemma C. 11 and so $\angle p b q \leqslant \pi-2 \arctan (0.09)<170^{\circ}$. The remaining case is that $p$ is an endpoint of $\sigma$ as radius $\left(B_{p}\right) \geqslant \operatorname{radius}\left(B_{q}\right)$ by assumption. That is, $p=u$ and $q=x_{2}$, or $p=v$ and $q=x_{0}$. In this case, since $q \in \operatorname{bd} B_{p}$ and $\operatorname{radius}\left(B_{q}\right) \leqslant \operatorname{radius}\left(B_{p}\right), \angle p b q<\pi / 2$.

Proof of Lemma 3.1(iv)(c) Let $B_{p}$ and $B_{q}$ be two consecutive protecting balls. Let $\sigma(p, q)$ denote the subcurve of $\sigma$ between $p$ and $q$. We show that $\sigma(p, q) \subset B_{p} \cup B_{q}$ by examining the possibilities for $p$ and $q$.

Consider the pairs $\left\{\left(u, x_{2}\right),\left(x_{0}, v\right)\right\}$. Because $x_{2} \in \operatorname{bd} B_{u}$ and $B_{u} \cap \sigma$ is an open curve by Lemma 3.1(iii)(b), $B_{u} \cap \sigma$ is exactly the subcurve between $u$ and $x_{2}$. Similarly, $B_{v} \cap \sigma$ is exactly the subcurve between $x_{0}$ and $v$.

The remaining possible pairs are adjacent weighted points in int $\sigma$. Let $B(a, r)$ denote the larger of $B_{p}$ and $B_{q}$. Let $B\left(a^{\prime}, r^{\prime}\right)$ denote the smaller one. Notice that both $B_{p}$ and $B_{q}$ are contained in $B(a, 3 r)$. By Lemma C.10, $\sigma(p, q)$ stays inside the cone with apex $a$, axis $a a^{\prime}$, and angular aperture $8 \omega$. Thus, Lemma C. 11 implies that $\sigma(p, q)$ enters $B\left(a^{\prime}, r^{\prime}\right)$ before leaving $B(a, r)$. After $\sigma(p, q)$ enters $B\left(a^{\prime}, r^{\prime}\right)$, $\sigma(p, q)$ cannot leave $B\left(a^{\prime}, r^{\prime}\right)$ and reenter $B\left(a^{\prime}, r^{\prime}\right)$ later because $B\left(a^{\prime}, r^{\prime}\right) \cap \sigma$ is an open curve by Lemma 3.1(iii)(b). Hence, $\sigma(p, q) \subset B_{p} \cup B_{q}$.

## C.5.3 Proof of Lemma 3.1(iv)(d)

Let $z$ be a point on the subcurve $\sigma(p, q)$. If $z=p$ or $q$, by Lemma 3.1(ii), the ball centered at $z$ with radius $\frac{\lambda \omega}{2500} f(z)$ lies within $B_{z}$, and we are done. Assume that $z \in \operatorname{int} \sigma(p, q)$ in the following.

Let $B(a, r)$ denote the larger of $B_{p}$ and $B_{q}$. Let $B\left(a^{\prime}, r^{\prime}\right)$ denote the smaller one. Let $H$ be the plane containing the circle bd $B_{p} \cap \mathrm{bd} B_{q}$. Let $C$ be the circle in $H$ concentric to bd $B_{p} \cap \mathrm{bd} B_{q}$ such that the angular aperture of the cone $K$ formed by connecting $a$ to $C$ is $16 \omega$. Since $r \geqslant r^{\prime}$, the angular aperture of the cone $K^{\prime}$ formed by connecting $a^{\prime}$ to $C$ is at least $16 \omega$. Refer to Fig. 4.

Notice that both $B_{p}$ and $B_{q}$ are contained in $B(a, 3 r)$. By Lemma C.10, $\sigma(p, q)$ resides in $K \cup K^{\prime}$, which means that the minimum distance between $\sigma(p, q)$ and $\operatorname{bd}\left(B_{p} \cup B_{q}\right)$ is at least the minimum distance between $K \cup K^{\prime}$ and $\mathrm{bd}\left(B_{p} \cup B_{q}\right)$. Denote the latter distance by $D$. Observe that $D$ is equal to the distance between $C$ and bd $B_{p} \cap \mathrm{bd} B_{q}$. So by Lemma C.11,

$$
\begin{equation*}
D \geqslant r \sin (\arctan (0.09))-r \sin (8 \omega)>0.009 r . \tag{10}
\end{equation*}
$$

Fig. 4 Proof of Lemma 3.1(iv)(d)

By Lemma 3.1(iv)(c), $\sigma(p, q) \subset B_{p} \cup B_{q}$, which is contained in $B(a, 3 r)$. Therefore, for any point $z \in \sigma(p, q)$,

$$
\begin{gather*}
\|a-z\| \leqslant 3 r  \tag{11}\\
\left\|a^{\prime}-z\right\| \leqslant\left\|a-a^{\prime}\right\|+\|a-z\| \leqslant 5 r . \tag{12}
\end{gather*}
$$

Suppose that $a \in \operatorname{int} \sigma$. As $f$ is 1-Lipschitz over int $\sigma, f(z) \leqslant f(a)+\|a-z\| \leqslant$ $f(a)+3 r$ by (11). By Lemma 3.1(ii), $r \geqslant \frac{\lambda \omega}{21} f(a) \Rightarrow f(z) \leqslant \frac{21+3 \lambda \omega}{\lambda \omega} r<\frac{22}{\lambda \omega} r$ as $\lambda \leqslant 0.01$ and $\omega \leqslant 0.01$. Substituting this lower bound of $r$ into (10) yields $D>$ $0.009 r>\frac{\lambda \omega}{2500} f(z)$.

If $a$ is an endpoint of $\sigma$, then $a^{\prime} \in \operatorname{int} \sigma$ and $a^{\prime}$ lies on the boundary of $B(a, r)$. So $f\left(a^{\prime}\right) \leqslant r$. We have $f(z) \leqslant f\left(a^{\prime}\right)+\left\|a^{\prime}-z\right\| \leqslant r+\left\|a^{\prime}-z\right\|$, which is at most $6 r$ by (12). Substituting this lower bound of $r$ into (10) yields $D>0.009 r \geqslant$ $0.0015 f(z)$.

## C. 6 Lemma 3.1(v)

We first show that the distance between two protecting balls $B_{p}$ and $B_{q}$ is at least $0.06 \cdot \min \left\{\operatorname{radius}\left(B_{p}\right)\right.$, radius $\left.\left(B_{q}\right)\right\}$ under certain conditions.

Lemma C. 12 Let $(p, s, q)$ be three weighted points in this order on the 1-face $\sigma$ (not necessarily consecutive). If $\|p-s\| \geqslant(1+\mu) \cdot \operatorname{radius}\left(B_{p}\right)$ for some $\mu \geqslant 0.02$, the distance between $B_{p}$ and $B_{q}$ is at least $0.06 \cdot \min \left\{\operatorname{radius}\left(B_{p}\right)\right.$, radius $\left.\left(B_{q}\right)\right\}$.

Proof Let $d\left(B_{p}, B_{q}\right)$ denote the distance between $B_{p}$ and $B_{q}$. We derive a contradiction below assuming that $d\left(B_{p}, B_{q}\right)<0.06 \cdot \min \left\{\operatorname{radius}\left(B_{p}\right)\right.$, radius $\left.\left(B_{q}\right)\right\}$.

By Lemma 3.1(iv)(a), for any protecting ball $B_{z}$ where $z \in \sigma, B_{z}$ does not strictly contain any weighted point adjacent to $z$. By Lemma 3.1(iii)(b), $B_{p} \cap \sigma$ and $B_{q} \cap \sigma$ are open curves. Therefore, $B_{p}$ cannot strictly contain $s$; otherwise, $B_{p}$ would have to contain a weighted point adjacent to $p$. Similarly, $B_{q}$ cannot strictly contain $s$.

Refer to Fig. 5. Let $\theta_{1}=\angle s p q$ and $\theta_{2}=\angle s q p$. By the assumption that $d\left(B_{p}, B_{q}\right)<0.06 \cdot \min \left\{\operatorname{radius}\left(B_{p}\right)\right.$, $\left.\operatorname{radius}\left(B_{q}\right)\right\}$, both $B_{p}$ and $B_{q}$ are contained in $B(a, 4 r)$, where $B(a, 4 r)$ denotes the larger of $B_{p}$ and $B_{q}$. Then, Lemma C. 10 implies that $\theta_{1}<8 \omega, \theta_{2}<8 \omega$ and $\angle p s q>\pi / 2$.

Let $\ell$ be the line through $s$ perpendicular to $q s$. Let $\ell^{\prime}$ be the line between $p$ and $s$, perpendicular to $p s$, and at distance $\mu \cdot \operatorname{radius}\left(B_{p}\right)$ from $s$. We have length $(\ell \cap p q s) \geqslant$

Fig. 5 Proof of Lemma C. 12

$\|p-s\| \sin \theta_{1} \geqslant(1+\mu) \sin \theta_{1} \cdot \operatorname{radius}\left(\boldsymbol{B}_{p}\right)$. Thus, $d \geqslant(1+\mu) \sin \theta_{1} \cos \left(\theta_{1}+\theta_{2}\right)$. radius $\left(B_{p}\right)$ and so $d / d^{\prime} \geqslant(1+\mu) \cos \theta_{1} \cos \left(\theta_{1}+\theta_{2}\right)$. In Fig. 5, $d\left(B_{p}, B_{q}\right) \geqslant d^{\prime \prime}$ and $d^{\prime \prime}=\operatorname{radius}\left(B_{p}\right) \cdot\left(\frac{d}{d^{\prime} \cos \theta_{1}}-1\right)$. Therefore,

$$
\begin{equation*}
d\left(B_{p}, B_{q}\right) \geqslant \operatorname{radius}\left(B_{p}\right) \cdot\left((1+\mu) \cos \left(\theta_{1}+\theta_{2}\right)-1\right) . \tag{13}
\end{equation*}
$$

As $\omega \leqslant 0.01$ and $\max \left\{\theta_{1}, \theta_{2}\right\}<8 \omega, \cos \left(\theta_{1}+\theta_{2}\right) \geqslant \cos (16 \omega) \geqslant 0.987$. By this lower bound of $\cos \left(\theta_{1}+\theta_{2}\right)$ and the assumption that $\mu \geqslant 0.02$, inequality (13) yields $d\left(B_{p}, B_{q}\right) \geqslant \operatorname{radius}\left(B_{p}\right) \cdot(0.987+0.987 \mu-1)>0.06 \operatorname{radius}\left(B_{p}\right)$. This contradicts our assumption that $d\left(B_{p}, B_{q}\right)<0.06 \cdot \min \left\{\operatorname{radius}\left(B_{p}\right)\right.$, $\left.\operatorname{radius}\left(B_{q}\right)\right\}$.

Proof of Lemma 3.1(v) Let $B_{p}$ and $B_{q}$ be two nonconsecutive protecting balls. We use $d\left(B_{p}, B_{q}\right)$ to denote the distance between $B_{p}$ and $B_{q}$.

If $p$ and $q$ belong to different 1 -faces, then $\|p-q\| \geqslant \max \{g(p), g(q)\}$. For any $x \in\{p, q\}$, Lemma 3.1(ii) implies that radius $\left(B_{x}\right)<5 \lambda g(x)<g(x) / 4$. Therefore, $d\left(B_{p}, B_{q}\right) \geqslant\|p-q\|-g(p) / 4-g(q) / 4>0.5 \cdot \max \{g(p), g(q)\}$.

Suppose that $p$ and $q$ belong to the same 1 -face $\sigma$. We prove Lemma 3.1(v) in this case by verifying that the conditions of Lemma C. 12 are satisfied for all pairs of nonadjacent weighted points on $\sigma$. We use $R_{p q}$ to denote 0.06 . $\min \left\{\operatorname{radius}\left(B_{p}\right)\right.$, radius $\left.\left(B_{q}\right)\right\}$.

Consider the pairs of weighted points $\left\{\left(x_{j}, x_{k}\right): 1 \leqslant j \leqslant k-2<m-2\right\}$. By Lemma C.3(ii), $\left\|x_{k-1}-x_{k}\right\| \geqslant \frac{6}{5+6 \lambda} r_{k}=\left(1+\frac{1-6 \lambda}{5+6 \lambda}\right) r_{k}$. Since $\lambda \leqslant 0.01, \frac{1-6 \lambda}{5+6 \lambda}>0.02$. So we can apply Lemma C. 12 to $(p, s, q)=\left(x_{k}, x_{k-1}, x_{j}\right)$ to obtain $d\left(B_{p}, B_{q}\right) \geqslant$ $R_{p q}$.

Consider the pairs of weighted points $\left\{\left(u, y_{m}\right),\left(u, x_{0}\right),(u, v)\right\}$. We have $x_{0} \in$ $B\left(v, \lambda \mathrm{f}_{\omega_{v}}(v)\right) \subset B\left(v, 0.3 \mathrm{f}_{\omega_{v}}(v)\right)$. By Lemma C.8, $y_{m} \in B\left(v, 0.3 \mathrm{f}_{\omega_{v}}(v)\right)$. Since $\|u-v\| \geqslant \max \{g(u), g(v)\} \geqslant \max \left\{\mathrm{f}_{\omega_{u}}(u), \mathrm{f}_{\omega_{v}}(v)\right\}$, for any $q \in\left\{y_{m}, x_{0}, v\right\}, d\left(B_{u}, B_{q}\right)$ $\geqslant(1-\lambda-0.3)\|u-v\| \geqslant \frac{1-\lambda-0.3}{\lambda} \operatorname{radius}\left(B_{u}\right)>20 \operatorname{radius}\left(B_{u}\right)$.

Consider the pairs of weighted points $\left\{\left(x_{k}, q\right): 2 \leqslant k \leqslant m-2\right.$ and $\left.q \in\left\{y_{m}, x_{0}, v\right\}\right\}$. By Lemma C.3(ii), $\left\|x_{k}-x_{k+1}\right\|=6 r_{k} / 5$. So we can apply Lemma C. 12 to $(p, s, q)=$ $\left(x_{k}, x_{k+1}, q\right)$ to obtain $d\left(B_{p}, B_{q}\right) \geqslant R_{p q}$.

The remaining set of weighted points to be considered is $\left\{\left(x_{m-1}, x_{0}\right),\left(x_{m-1}, v\right)\right.$, $\left.\left(y_{m}, v\right)\right\}$. Since $B_{x_{m-1}} \cap B\left(x_{0}, r_{0 m-1}\right)=\emptyset$ and radius $\left(B_{x_{0}}\right)=\frac{4}{5} r_{0 m-1}, d\left(B_{x_{m-1}}, B_{x_{0}}\right)$ $>\frac{1}{5} \operatorname{radius}\left(B_{x_{0}}\right)$. By Lemma C.5(i), $\left\|x_{m-1}-x_{0}\right\|>\frac{2}{1+\lambda} r_{m-1}>1.9 r_{m-1}$ as $\lambda \leqslant 0.01$. So we can apply Lemma C. 12 to $(p, s, q)=\left(x_{m-1}, x_{0}, v\right)$ to obtain $d\left(B_{p}, B_{q}\right) \geqslant$ $R_{p q}$. To bound $d\left(B_{y_{m}}, B_{v}\right)$, we first relate radius $\left(B_{y_{m}}\right)$ and $\left\|y_{m}-x_{0}\right\|$. Since $B_{y_{m}}$ and
$B_{x_{0}}$ are orthogonal, radius $\left(B_{y_{m}}\right)=\sqrt{\left\|y_{m}-x_{0}\right\|^{2}-\left(\frac{4}{5} r_{0 m-1}\right)^{2}}$. By Lemma C.5(ii), $\left\|y_{m}-x_{0}\right\| \leqslant 4 r_{0 m-1}$. Thus, radius $\left(B_{y_{m}}\right) \leqslant \sqrt{24 / 25}\left\|y_{m}-x_{0}\right\| \Rightarrow\left\|y_{m}-x_{0}\right\|>$ $1.02 \operatorname{radius}\left(B_{y_{m}}\right)$. So we can apply Lemma C. 12 to $(p, s, q)=\left(y_{m}, x_{0}, v\right)$ to obtain $d\left(B_{p}, B_{q}\right) \geqslant R_{p q}$.

## Appendix D: Lemma 5.15

We first prove four topological results in the next section. Afterwards, we use them to prove Lemma 5.15.

## D. 1 Technical Lemmas

The next lemma states that for any edge $e \in \operatorname{star}(p, \sigma)$ where $p$ is a point on a 2 -face $\sigma,\left.V_{e}\right|_{\sigma}$ is an open curve under certain conditions. So each facet of $V_{p}$ contributes at most one curve to bd ( $V_{p} \cap \sigma$ ).

Lemma D. 1 Let $S$ be the current admissible point set. Assume that $\|a-b\| \geqslant$ $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. Let $p$ be a point in $S \cap \sigma$ for some 2 -face $\sigma$. Suppose that $\operatorname{Infringed}(p, \sigma)$ and $\operatorname{CurveNormal}\left(p, \sigma, \phi_{c}\right)$ return null and $\operatorname{size}(t, \sigma)<0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any triangle $t \in \operatorname{star}(p, \sigma)$. Then, $\left.V_{e}\right|_{\sigma}$ is an open curve for any edge $e \in \operatorname{star}(p, \sigma)$.

Proof Take an edge $p q \in \operatorname{star}(p, \sigma)$. As Infringed $(p, \sigma)$ returns null, $q \in \sigma$. No curve in $\left.V_{p q}\right|_{\sigma}$ is closed; otherwise, CurveNormal $\left(p, \sigma, \phi_{c}\right)$ would return a point. So $\left.V_{p q}\right|_{\sigma}$ is a collection of open curve(s). Take any open curve $\xi$ in $\left.V_{p q}\right|_{\sigma}$. If $V_{p q}$ avoids bd $\sigma$, both endpoints of $\xi$ belong to bd $V_{p q}$. Otherwise, $V_{p q}$ intersects bd $\sigma$ exactly once by Lemma 5.3, and so at least one endpoint of $\xi$ belongs to bd $V_{p q}$.

Assume that $\left.V_{p q}\right|_{\sigma}$ consists of two or more open curves. We derive a contradiction below. There are at least three distinct curve endpoints $x_{1}, x_{2}$, and $x_{3}$ in bd $V_{p q}$. By assumption, the weighted distance between $p$ and $x_{i}$ is less than $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for $1 \leqslant i \leqslant 3$. Then, $x_{i} \in B(p, \sqrt{2}$ range $(p))$ for $1 \leqslant i \leqslant 3$ by Lemma 5.8 and $\angle n_{\sigma}(p), V_{p q}<4 \omega$ by Lemma 5.9. Also, by Lemma 5.7, $n_{\sigma}(p)$ makes an angle less than $26 \omega$ radians with the Voronoi edges containing $x_{1}, x_{2}$ and $x_{3}$.

If any two points in $\left\{x_{1}, x_{2}, x_{3}\right\}$ lie on the same edge of $V_{p q}$, say $x_{1}$ and $x_{2}$, then $x_{1} x_{2}$ is parallel to that edge and so $\angle n_{\sigma}(p), x_{1} x_{2}<26 \omega$. This is a contradiction because $\angle n_{\sigma}(p), x_{1} x_{2}>\pi / 2-2 \omega$ by Lemma 5.2(iii).

Suppose that $x_{1}, x_{2}$, and $x_{3}$ lie on three distinct Voronoi edges. The support lines of these three edges bound a convex polygon $Q$ containing $V_{p q}$. ( $Q$ is possibly unbounded.) Refer to Fig. 6. Let $\vec{d}$ be the projection of $n_{\sigma}(p)$ onto the plane of $V_{p q}$. We have $\angle n_{\sigma}(p), \vec{d}=\angle n_{\sigma}(p), V_{p q}<4 \omega$. So each side of $Q$ makes an angle less than $4 \omega+26 \omega=30 \omega$ radians with $\vec{d}$. Thus, the angle at some vertex of $Q$ is obtuse, say the vertex between $x_{1}$ and $x_{2}$. It follows that $\angle \vec{d}, x_{1} x_{2}<30 \omega$. However, Lemma 5.2(iii) implies that $\angle \vec{d}, x_{1} x_{2} \geqslant \angle n_{\sigma}(p), x_{1} x_{2}-\angle n_{\sigma}(p), \vec{d}>\pi / 2-6 \omega$, a contradiction.

The next result shows that $\mathrm{bd}\left(V_{p} \cap \sigma\right)$ is not far from $p$ under certain conditions.

Fig. 6 The convex polygon denotes $V_{p q}$

Lemma D. 2 Let $S$ be the current admissible point set. Assume that $\|a-b\| \geqslant$ $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. Let $p$ be a point in $S \cap \sigma$ for some 2 -face $\sigma$. Suppose that Infringed $(p, \sigma)$ and $\operatorname{CurveNormal}\left(p, \sigma, \phi_{c}\right)$ return null and $\operatorname{size}(t, \sigma)<0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any triangle $t \in \operatorname{star}(p, \sigma)$. Then, $\operatorname{bd}\left(V_{p} \cap \sigma\right) \subset B(p, 6 \operatorname{range}(p))$.

Proof If $p$ is unweighted, $V_{p}$ avoids bd $\sigma$ by Lemma 5.3. So $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ contains the curves in $\left\{\left.V_{p q}\right|_{\sigma}\right.$ : edge $\left.p q \in \operatorname{star}(p, \sigma)\right\}$. If $p$ is weighted, $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ contains the above curves as well as $V_{p} \cap \mathrm{bd} \sigma$.

When $p$ is weighted, by Lemma 5.3, bd $V_{p}$ intersects bd $\sigma$ exactly twice. So $V_{p} \cap$ $\mathrm{bd} \sigma$ is an open curve. Then, it follows from Lemma 3.1(iv)(c) that $V_{p} \cap \mathrm{bd} \sigma \subset B_{p} \subset$ $B(p, 6$ range $(p))$.

Take an edge $p q \in \operatorname{star}(p, \sigma)$. By Lemma D.1, $\left.V_{p q}\right|_{\sigma}$ is an open curve. Let $x_{1}$ and $x_{2}$ be its endpoints. If $x_{i} \in \operatorname{bd} V_{p q}$, by assumption, the weighted distance between $p$ and $x_{i}$ is less than $\mathrm{lfs}_{\varepsilon}^{*}$. Then, $\left\|p-x_{i}\right\|<\sqrt{2} \operatorname{range}(p)$ by Lemma 5.8. If $x_{i} \in$ int $V_{p q}, p$ must be weighted and $x_{i} \in V_{p} \cap \mathrm{bd} \sigma \subset B_{p}$. Hence, $\max _{1 \leqslant i \leqslant 2}\left\|p-x_{i}\right\|<$ $\sqrt{2} \operatorname{range}(p)$ and $\left\|x_{1}-x_{2}\right\| \leqslant\left\|p-x_{1}\right\|+\left\|p-x_{2}\right\|<2 \sqrt{2} \operatorname{range}(p)$.

For any point $\left.z \in \operatorname{int} V_{p q}\right|_{\sigma}$, since CurveNormal $\left(p, \sigma, \phi_{c}\right)$ returns null, $\angle x_{1} z x_{2}>$ $\pi-4 \phi_{c}>\pi-\pi / 4-16 \omega>\pi / 2$. Therefore, $\max _{1 \leqslant i \leqslant 2}\left\|x_{i}-z\right\| \leqslant\left\|x_{1}-x_{2}\right\|<$ $2 \sqrt{2}$ range $(p)$. Hence, $\|p-z\| \leqslant\left\|p-x_{1}\right\|+\left\|x_{1}-z\right\|<6 \operatorname{range}(p)$.

Lemma D. 2 motivates us to examine $B(p, \operatorname{6range}(p)) \cap \sigma$ which contains bd $\left(V_{p} \cap\right.$ $\sigma)$. The next results shows that $V_{p}$ contains a topological disk in $B(p, 6 \operatorname{range}(p)) \cap \sigma$ under certain conditions.

Lemma D. 3 Let $S$ be the current admissible point set. Assume that $\|a-b\| \geqslant$ $0.03 \mathrm{lfs}_{\varepsilon}^{*}$ for any $a, b \in S$. Let $p$ be a point in $S \cap \sigma$ for some 2 -face $\sigma$. Suppose that $\operatorname{size}(t, \sigma)<0.03$ lfs $_{\varepsilon}^{*}$ for any triangle $t \in \operatorname{star}(p, \sigma)$. Let $D \subset B(p, 6 \operatorname{range}(p)) \cap \sigma$ be a topological disk such that $\operatorname{bd} D \subset \operatorname{bd} V_{p}, \operatorname{bd} D$ intersects some edge of $V_{p}$, and int $D \cap \mathrm{bd} V_{p}=\emptyset$. Then $D \subset V_{p}$.

Proof By assumption, bd $D$ intersects an edge of $V_{p}$. So bd $D$ intersects $V_{t}$ for some triangle $t \in \operatorname{star}(p, \sigma)$. By assumption, ortho $(t) \leqslant \operatorname{size}(t, \sigma)<0.03$ lfs $_{\varepsilon}^{*}$. So $\angle n_{\sigma}(p), V_{t}<26 \omega$ by Lemma 5.7. Assume to the contrary that $D \not \subset V_{p}$. As int $D \cap$ bd $V_{p}=\emptyset$, we conclude that int $D$ is outside $V_{p}$. The closed curve bd $D$ splits bd $V_{p}$ into two topological disks, and let $U$ be one of them. So $D \cup U$ is a topological sphere.

Fig. 7 Proof of Lemma D. 3

Refer to Fig. 7. Let $\ell$ be a line outside $V_{p}$, parallel to $V_{t}$, and arbitrarily close to $V_{t}$. Since int $D$ is outside $V_{p}, \ell$ must intersect int $D$ at a point $y$. As $D \cup U$ is a closed surface, $\ell$ must intersect $D \cup U$ at another point $z$. Moreover, as $\ell$ is outside $V_{p}, z$ must belong to $D$. Since $y z$ is parallel to $\ell, \angle n_{\sigma}(p), y z=\angle n_{\sigma}(p), V_{t}<26 \omega$. However, since $y, z \in B(p, 6 \operatorname{range}(p)) \cap \sigma$, Lemma 5.2(iii) implies that $\angle n_{\sigma}(p), y z>$ $\pi / 2-2 \omega$, a contradiction.

The possibility that $V_{p}$ may intersect $\operatorname{bd} \sigma$ complicates the analysis because $\mathrm{bd}\left(V_{p} \cap \sigma\right)$ needs not be a subset of $\mathrm{bd} V_{p}$. Nonetheless, the next result shows that if $\mathrm{bd}\left(V_{p} \cap \sigma\right)$ contains two or more curves, we can always find a "most nested curve" in $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ that lies on bd $V_{p}$.

Lemma D. 4 Let $S$ be the current admissible point set. Let p be a point in $S \cap \sigma$ for some 2 -face $\sigma$. Let $M=B(p, 6 \operatorname{range}(p)) \cap \operatorname{mani}(\sigma)$. Suppose that $\operatorname{bd}\left(V_{p} \cap \sigma\right) \subset M$ and $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ contains two or more closed curves. There exists a closed curve $\zeta$ in $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ such that $\zeta \subset$ bd $V_{p}$ and the topological disk bounded by $\zeta$ in $M$ does not contain other curves in $\operatorname{bd}\left(V_{p} \cap \sigma\right)$.

Proof By Lemma 5.2(ii), $M$ is a topological disk. So each closed curve $\xi$ in $\operatorname{bd}\left(V_{p} \cap\right.$ $\sigma$ ) bounds a topological disk in $M$, which we denote by $D_{\xi}$. Pick a most nested curve $\xi$ in $\operatorname{bd}\left(V_{p} \cap \sigma\right)$, i.e., $D_{\xi}$ does not contain other curves in $\operatorname{bd}\left(V_{p} \cap \sigma\right)$. If $\xi$ does not contain $p, \xi$ lies on the boundary of bd $V_{p}$, and we are done.

Suppose that $\xi$ contains $p$. So $p$ is weighted. By Lemma 5.3, bd $V_{p}$ intersects $\mathrm{bd} \sigma$ exactly twice. Thus, $V_{p} \cap \mathrm{bd} \sigma$ is an open curve contained in $\xi$, and any curve in $\mathrm{bd}\left(V_{p} \cap \sigma\right)$ other than $\xi$ must avoid bd $\sigma$. It follows from Lemma 3.1(iii)(b) that $B(p, 6 \operatorname{range}(p)) \cap \operatorname{bd} \sigma$ is an open curve, which cuts across $M$. We have just shown that for any curve $\eta$ in $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ other than $\xi, \eta$ cannot cross $B(p, 6 \operatorname{range}(p)) \cap$ $\operatorname{bd} \sigma$. This implies that $D_{\eta}$ cannot contain $\xi$. Hence, either $\eta$ or the "most nested curve" in bd ( $V_{p} \cap \sigma$ ) inside $D_{\eta}$ satisfies the lemma.

## D. 2 Proof of Lemma 5.15

Assume that bd ( $V_{p} \cap \sigma$ ) consists of two or more closed curves. We derive a contradiction in the following.

Let $M=B(p, 6 \operatorname{range}(p)) \cap \operatorname{mani}(\sigma)$. By Lemma D.2, $\operatorname{bd}\left(V_{p} \cap \sigma\right) \subset M$. By Lemma 5.2(ii), $M$ is a topological disk. Lemma D. 4 implies that there is a closed

Fig. 8 The line $\ell$ in the plane of $V_{e}$ is normal to $V_{e} \cap \sigma$ at $x$. So $n_{\sigma}(x)$ projects onto $\ell$

curve $\zeta$ in $\operatorname{bd}\left(V_{p} \cap \sigma\right)$ such that $\zeta \subset \operatorname{bd} V_{p}$ and $\zeta$ bounds a topological disk $D_{\zeta}$ in $M$ that lies inside $V_{p}$.

Consider the support planes of the facets of $V_{p}$ intersected by $\zeta$. Each such plane bounds a halfspace containing $V_{p}$. Let $Q$ denote the polytope at the common intersection of all these halfspaces. So $V_{p} \subseteq Q$.

Since $M \backslash D_{\zeta}$ is connected, we can find a path $\gamma$ in $M$ that connects $D_{\zeta}$ to another curve in bd $\left(V_{p} \cap \sigma\right)$ such that the interior of $\gamma$ avoids $D_{\zeta}$. Since $D_{\zeta} \subset V_{p}, \gamma$ must leave $V_{p}$ and $Q$ when it leaves $D_{\zeta}$. So $\gamma$ must return to $V_{p}$ later in order to reach $\mathrm{bd}\left(V_{p} \cap \sigma\right)$ again. This implies that $\gamma$ must return to $\mathrm{bd} Q$ at some point $y$. By construction, the boundary facet of $Q$ containing $y$ must have the same support plane as some facet $V_{e}$ of $V_{p}$ that $\zeta$ intersects. Let $H_{e}$ denote the support plane of $V_{e}$. Let $x$ be the point in $V_{e} \cap \zeta$ closest to $y$. By Lemma D.1, $V_{e} \cap \zeta=V_{e} \cap \sigma$, and it is an open curve. We consider the two cases of $x$ lying in the interior of $V_{e} \cap \sigma$ and $x$ being an endpoint of $V_{p} \cap \sigma$. We derive a contradiction in each case, thus completing the proof.

Suppose that $x$ lies in the interior of $V_{e} \cap \sigma$. Any endpoint of $V_{e} \cap \sigma$ lies on an edge of $V_{p}$. So the weighted distances between $p$ and the endpoints of $V_{e} \cap \sigma$ are less than lfs $\varepsilon_{\varepsilon}^{*}$ by the assumption of the lemma. Then, Lemma 5.9 implies that $\angle n_{\sigma}(p), H_{e}<$ $4 \omega$. Since $x \in \operatorname{int}\left(V_{e} \cap \sigma\right), x y$ is normal to $V_{e} \cap \sigma$. So $\angle n_{\sigma}(x), H_{e}=\angle n_{\sigma}(x), x y$. By Lemma 5.2(i) and (iii), we get $\angle n_{\sigma}(p), H_{e} \geqslant \angle n_{\sigma}(x), x y-\angle n_{\sigma}(p), n_{\sigma}(x) \geqslant$ $\angle n_{\sigma}(p), x y-2 \angle n_{\sigma}(p), n_{\sigma}(x)>\pi / 2-6 \omega$, a contradiction.

Suppose that $x$ is an endpoint of $V_{e} \cap \sigma$. Refer to Fig. 8. So $x$ lies on some edge of $V_{p}$. Let this edge be $V_{t}$ for some triangle $t \in \operatorname{star}(p, \sigma)$. Since $x$ is the closest point to $y, x y$ must lie inside a sharp wedge bounded by $V_{t}$ and the line in $H_{e}$ normal to $V_{e} \cap \sigma$ at $x$. Observe that $\angle n_{\sigma}(x), x y \leqslant \angle n_{\sigma}(x), V_{t}$ in this case. By Lemma 5.2(i) and (iii), we have $\angle n_{\sigma}(x), x y \geqslant \angle n_{\sigma}(p), x y-\angle n_{\sigma}(p), n_{\sigma}(x)>\pi / 2-4 \omega$. On the other hand, by Lemma 5.7, $\angle n_{\sigma}(x), V_{t} \leqslant \angle n_{\sigma}(p), V_{t}+\angle n_{\sigma}(p), n_{\sigma}(x)<28 \omega$, a contradiction.
