### Abstract

Antagonists of cannabinoid receptor 1 (CB1) have potential for the treatment of several diseases such as obesity, liver disease and diabetes. Recently, development of several CB1 antagonists was halted due to adverse central nervous system (CNS) related side effects observed with rimonabant, the first clinically approved CB1 inverse agonist. However, recent studies indicate that regulation of peripherally expressed CB1 with CNS-sparing compounds is a viable strategy to treat several important disorders. Our efforts aimed at rationally designing peripherally restricted CB1 antagonists have resulted in compounds that have limited blood-brain barrier (BBB) permeability and CNS exposure in preclinical *in vitro* and *in vivo* models. Typically, compounds with high topological polar surface areas (TPSAs) do not cross the BBB passively. Compounds with TPSAs higher than rimonabant (rimonabant TPSA = 50) and excellent functional activity with limited CNS penetration were identified. These compounds will serve as templates for further optimization.

### Keywords

CB1; peripheral; antagonist; cannabinoid; topological polar surface area

### Introduction

The endocannabinoid system (ECS) consists of receptors, transporters, endocannabinoids, and the enzymes involved in synthesis and degradation of endocannabinoids.<sup>1</sup> There have been two cannabinoid receptors (CBRs) identified to date, CB1 and CB2. CB1 and CB2 are both G protein-coupled receptors (GPCRs) and their primary function is to activate inhibitory G proteins (Gi/o).<sup>1–2</sup> The ECS is responsible for many important physiological processes and regulation of these processes holds promise for the treatment of several diseases. ECS components are under evaluation for the treatment of obesity, liver disease, diabetes, pain and inflammation.<sup>2</sup>

The CB1 receptor is expressed throughout the body, however, it is found at much greater concentrations in the central nervous system (CNS). There has been great interest in the use of CB1 antagonists for the treatment of metabolic disorders, such as obesity and diabetes. Rimonabant (SR141716A, **1**, Figure 1), a potent and selective CB1 inverse agonist/antagonist, was clinically approved to treat obesity in Europe. Unfortunately, **1** produced

serious CNS-related side effects such as anxiety, depression and suicidal ideation in patients, leading to its withdrawal from European markets and denial of approval in the United States.<sup>3</sup> Upon discovery of rimonabant's side effects several other CB1 antagonists, such as taranabant, otenabant (**2**), and ibipinabant, were pulled from development due to regulatory concerns.<sup>4</sup>

A strategy to take advantage of the therapeutic potential of CB1 antagonism and avoid the CNS-related adverse effects is to generate CB1 antagonists that do not cross the blood-brain barrier (BBB). This strategy is being pursued by several groups and a small set of CB1 antagonists that do not cross the BBB have been reported (**3–6**, Figure 2).<sup>5</sup> However, none of these peripherally restricted CB1 antagonists have been fully characterized or their efficacy demonstrated clinically.

Our group has pursued a two-pronged strategy to develop peripherally restricted CB1 antagonists. The first strategy involved development of CB1 antagonists that have a permanent charge. Charged compounds do not normally cross the BBB unless they are acted upon by a transporter.<sup>6</sup> Results for this strategy have been previously reported.<sup>7</sup> The second strategy was to target compounds with high topological polar surface areas (TPSAs). It has been shown that compounds with higher TPSAs have lower permeability into the CNS.<sup>8</sup> Higher TPSAs can be achieved by adding polar groups, such as sulfonamide or sulfamide, or by replacing existing functional groups with more polar functional groups. This strategy led to the identification of compounds **7** and **8** that we have previously reported. While these compounds were promising, their selectivity for CB1 over CB2 was only modest. Here we describe our ongoing efforts towards designing peripherally restricted CB1 antagonists with improved properties. This study evolved to include a more empirical approach that was based more on SAR than on computational parameters. We have been able to design, synthesize, and characterize highly selective CB1 antagonists that appear to be peripherally restricted.

## Results

### Ligand design and pharmacological characterization

Compounds were synthesized, purified, characterized and tested as has been described under the “Experimental Section”. All compounds were tested *in vitro* as antagonists using a calcium mobilization assay as has been previously described.<sup>7</sup> The ability of each compound to antagonize functional activation of CB1 was quantitatively measured and expressed as its apparent dissociation affinity constant ( $K_e$ ). Compounds that were found to be potent ( $K_e$  ~100 nM or less) using the functional assay were subsequently characterized using radioligand displacement of either [<sup>3</sup>H]SR141716A or [<sup>3</sup>H]CP55940 at CB1 and CB2. Equilibrium dissociation constant ( $K_i$ ) values were determined at each receptor.

During our studies of charged compounds, carboxylic acids were examined due to the fact that they are negatively charged at the physiological pH. Around the same time, carboxylic acid **9** (Figure 3) was reported by another group to be a CB1 antagonist.<sup>5d</sup> This finding led to the synthesis and evaluation of carboxylic acid **10** (Table 1). Compound **10** was only moderately active ( $K_e$  = 1170 nM). However, examination of the structure of **2** revealed a primary amide at the 4-position of the piperidine ring (Figure 1). This amide was in a similar position as the carboxylic acid functionality of compound **10**, leading to the decision to convert carboxylic acid **10** to amide **11** (Figure 3). Amide **11** lacked the charged nature of a carboxylic acid but it did have hydrogen bonding ability that could lower its permeability into the CNS. Compound **11** was found to be a potent CB1 antagonist having a  $K_e$  of 0.44 nM and was also highly selective for CB1 over CB2 (CB2:CB1 of 1600). Interestingly, the 4-phenylpiperidine-4-carboxamide group was also reported on a closely related pyrrole

scaffold.<sup>5c</sup> Compound **11** was advanced into a Madin-Darby canine kidney cells transfected with the human MDR1 gene (MDCK-mdr1) model of BBB penetration, which is widely used to predict *in vivo* permeability of compounds.<sup>9</sup> The potency, selectivity, and relatively low permeability of compound **11** across the MDCK-mdr1 cells (apical (A) to basal (B), 8%) made it an interesting starting point for further modifications towards designing potent and selective CB1 antagonists that do not cross the BBB.

Compound **11** served as a starting point for several modifications to the amine portion of the pyrazole C-3 carboxamide (Figure 4, Table 2). One of the first modifications of compound **11** studied was the replacement of the phenyl group. Compound **12** was targeted because it represented a hybrid of compounds **11** and **2**. Compound **12** also closely resembles the Sanofi-aventis compound **5**. However, compound **12**'s potency (Ke CB1 = 91 nM) and selectivity (ratio CB2:CB1 of 28.3) did not warrant further investigation of this compound. Next, the reversal of the primary amide of compound **11** became of interest. To realize this, both compounds **13** and **14** needed to be synthesized as precursors of reverse amide compound **15**. However, both compound **13** and **14** were interesting in their own right. Compound **13** added the additional functionality of a carbamate; this was a functionality that had not been pursued in our laboratory, and it also had good potency (Ke CB1 = 20.2 nM) and selectivity (ratio CB2:CB1 of ~50). Compound **14** was of interest because it replaced the primary amide of **11** with a primary amine. This maintained the possibility of hydrogen bonding, and increased the basicity of the molecule. This amine group proved to be detrimental to potency (Ke CB1 = 485 nM). However, the amine group in compound **14** also allowed for the introduction of different functionalities. The amine group of compound **14** was used to make the reverse amide compound **15** which was only weakly active (Ke CB1 = 201 nM). Sulfonamide **16**, which was also made from amine **14**, had higher TPSA compared to compound **11** and was potent but only moderately selective for CB1 over CB2 (Ke CB1 = 3.5 nM, ratio of CB2:CB1 of 5.64). Finally, amine **14** also allowed for the synthesis of urea **17a**. Urea **17a** proved to be a potent CB1 antagonist (Ke CB1 = 2.4 nM) and had good selectivity against CB2 (ratio CB2:CB1 of ~425). Compound **17a** was advanced into the *in vitro* model of BBB permeability (MDCK-mdr1, apical to basal) and was predicted not to cross the BBB (Table 2, <1% transported). These results spawned the synthesis of a small library of ureas **17b–17k**, which had potencies (Ke) ranging from 0.5 nM to >10,000 nM against CB1. Several of these compounds were very selective with five of the ten compounds being over 100-fold selective for CB1 over CB2 (Table 2).

The positive results for compound **17a** also led to the exploration of 4- and 3-aminopiperidine and cyclohexyl amides as different spacers between the pyrazole amide and their polar functionality (Figure 5, Table 3). Structural series **18** was chosen because it offered similar spacing to compound **17a** and presented the opportunity for rapid derivatization off the piperidine nitrogen. Due to the positive results observed for compounds **18a–l** (7 out of the 12 compounds had Ke <100 nM against CB1, and 4 analogues having CB2:CB1 ratios greater than 100), other amino-piperidine linkers were explored. The 1,3-disubstituted aminopiperidine series **19** and **20** explored the importance of the effect of an alternative juxtaposition of substituents and the introduction of stereochemistry versus the 4-aminopiperidine linker of structural series **18**. Both enantiomers were explored to examine the effect of chirality on potency and selectivity. Positive results were obtained with compounds **19a–j**, with three of the ten analogues having Ke values below 100 nM at CB1, and two analogues were over 100-fold selective for CB1 versus CB2. Compounds **20a–j** were also of interest with three of the ten analogues having Ke (CB1) less than 30 nM; in addition three of the ten analogues were over 100-fold selective for CB1 vs CB2. Finally, since sulfonamide **7** and sulfamide **8** have been found to be potentially useful in the development of periphery restricted CB1 antagonists,<sup>7</sup> ureas of

structure **21** were targeted. In general these compounds were only weakly active and compounds **21a–e** were not pursued further.

## Synthesis

Compound **10** (Scheme 1) was prepared by first making the acid chloride of the readily available acid **22**.<sup>10</sup> Acid **22** was treated with oxalyl chloride and a catalytic amount of dimethylformamide (DMF) in dichloromethane to form the desired acid chloride. This acid chloride was then treated with amino acid **23** in the presence of triethylamine to yield compound **10** in 67% yield. Carboxylic acid **10** was converted to amide **11** by the use of (benzotriazol-1-yloxy)tris(dimethylamino)phosphonium hexafluorophosphate (BOP), triethylamine, and ammonium chloride in 46% yield.

Amino amide **12** was made by reacting acid **22** with commercially available piperidine **24** under BOP coupling conditions, and this reaction produced compound **12** in 46% yield (Scheme 2). The protected amine **13** was made by the coupling of acid **22** and readily available amine **25**.<sup>11</sup> The Boc group of compound **13** was removed using 30% trifluoroacetic acid (TFA) in dichloromethane to yield amine **14** in 87% yield. Amine **14** was used as a common intermediate for compounds **15**, **16**, and **17a–k**. Acetyl amide **15** was made by reacting amine **14** with acetic anhydride and pyridine in 71% yield. Sulfonamide **16** was formed by the reaction of **14** with methanesulfonyl chloride and triethylamine in 65% yield. Urea **17a** was synthesized in 45% yield by reacting amine **14**, *tert*-butyl isocyanate, and triethylamine at 40°C in THF. Synthesis of ureas **17b–k** was accomplished by reacting amine **14**, the appropriate isocyanate, and triethylamine in tetrahydrofuran (THF) at room temperature. These reactions proceeded in yields that ranged from 58%–74%.

Compounds **18a**, **19a**, and **20a** were synthesized by the coupling of the appropriate commercially available amine to acid **22** in the presence of BOP and triethylamine in yields ranging from 88%–96% (Scheme 3). Treatment of compounds **18a**, **19a**, and **20a** with trifluoroacetic acid in dichloromethane produced the amines **18b**, **19b**, and **20b**. The amines **18b**, **19b**, and **20b** were reacted with acetic anhydride and pyridine to produce amides **18c**, **19c**, and **20c** respectively in yields ranging from 81%–87%. Sulfonamides **18d**, **19d**, and **20d** were made by reacting amines **18b**, **19b**, and **20b** with methanesulfonyl chloride and triethylamine in THF. Ureas **18f,h–l**, **19e–j**, and **20e–j** were made by reacting the appropriate amine with the appropriate isocyanate in dichloromethane or THF. The *N-tert*-butylpiperidine carboxamide **18f** was converted to the unsubstituted piperidine carboxamide **18g** in 81% yield by stirring **18f** in 50% TFA in dichloromethane.<sup>12</sup> The sulfamide **18e** was synthesized from the reaction of **18b** with excess sulfamide in dioxane at 90° C in 67% yield (Scheme 4).<sup>7</sup> Ureas **21a–e** were made as a mixture of *cis/trans* isomers from the previously described amine **26** in yields ranging from 71%–98%.<sup>7</sup>

## *In vitro* metabolic stability and *in vivo* evaluation of brain penetration

A small set of compounds that were potent, selective and were predicted not to penetrate the CNS as determined using the MDCK-mdr1 assay were tested for *in vitro* metabolic stability (Table 4). Stability was measured in human plasma and human hepatic S9 fractions to gauge any metabolic liabilities that might be present with these compounds. All compounds tested had good stability in plasma. Stabilities of compounds in S9 fractions were more variable than stabilities in plasma. However, all compounds except **17b** displayed metabolic stabilities similar to or greater than compound **1**.

Compounds were prioritized and progressed into *in vivo* experiments in mice for analysis of brain penetration (Table 5). Compound **13** was not progressed due to its relatively low selectivity compared with other compounds found in Table 4, and compound **17b** was not

progressed due to its relatively low stability in S9 fractions. Ureas **17a** and **18f** along with carbamate **18a** were chosen and evaluated *in vivo*. Urea **17a** was bioavailable with either oral or intra-peritoneal (ip) dosing. Brain levels of **17a** were below the lower limit of quantitation when dosed orally and its brain to plasma ratio was 0.03 with ip dosing at one hour. Carbamate **18a** was also bioavailable with either oral or ip dosing. When dosed by ip injection, carbamate **18a** had a brain to plasma ratio of 0.02 at one hour. Urea **18f** was also bioavailable with oral or intra-peritoneal dosing. However, brain to plasma ratios for urea **18f** were 0.16 with oral dosing at one hour and 0.38 with intraperitoneal dosing at one hour. Since unperfused brains were examined and because the volume of blood in the unperfused brain is ~2–4%<sup>13</sup>, these promising results indicated that **17a** and **18a** had little to no permeability into the brain as expected while **18f** was not selective for the periphery.

## Discussion

In this publication we report our ongoing efforts to produce peripherally selective CB1 antagonists that may be useful in treating a wide range of clinical indications. We have now identified several highly selective CB1 antagonists that are metabolically stable with limited oral bioavailability. The addition of polarity to 3-carboxamide position has been found to be advantageous. Sulfonamide **7** came out of our efforts to synthesize CB1 antagonists that had high TPSAs.<sup>7</sup> Those efforts focused on compounds that contained sulfonamide and sulfamide functionality because of the relatively large TPSA for these functional groups. Continued efforts along those lines have yielded more positive results, including two new sulfonamides, **19d**, and **20d**, that are more selective than **7**. Sulfonamide **7** demonstrated modest selectivity for CB1 versus CB2 (16 fold), but both **19d** and **20d** demonstrated over 100-fold selectivity. This improvement in selectivity came with an increase in potency as well; sulfonamide **20d** is 16-fold more potent than **7**.

Sulfonamides and sulfamides were not the only polar functionalities to be utilized. Amides, ureas, and carbamates were also synthesized to increase the polarity. Examples of all three have been found to be potent and selective. However, it should be noted that polar groups caused a loss of activity unless they were accompanied by additional lipophilicity. This is best demonstrated by comparing compounds **18g** to **18h**. The unsubstituted piperidine carboxamide **18g** contained no additional lipophilicity and had poor activity at CB1 (**18g**, Ke CB1 = 4097 nM). With the addition of an ethyl group, such as found in compound **18h**, the activity was significantly increased (**18h**, Ke CB1 = 20.5 nM). The enhancing effects of lipophilicity on potency at CB1 could be also seen in compounds **13–17k**.

The shape of the functional group seemed to have impact on potency. The linear (4-aminopiperidine) linker seemed to be favored over the bent (3-aminopiperidine) linker for potency. Structure **18** was found to be the most potent analogue in 6 out of the 10 examples where structures **18–20** possessed the same substituent. However, it should be noted that those 6 analogues were all ureas or carbamates. Of the analogues that favored the bent (3-aminopiperidine) linker only one contained a urea (**20g**). Amine (**19b** and **20b**), amide (**19c**), and sulfonamide (**20d**) substituents favored the 3-aminopiperidine linker. Of the two bent (**19**, (3S)-3-aminopiperidine; **20**, (3R)-3-aminopiperidine) linkers, the R enantiomer (**20**) was the most favored for activity at CB1. Analogues of structure **20** were found to be more potent than their corresponding analogues of structure **19** seven out of ten times. The 4-amino-4-phenylpiperidine linker present in compounds **13–17k** was by far the most potent linker tested. However, it was difficult to determine if the improved potency observed with the 4-amino-4-phenylpiperidine linker was due to shape or the greater lipophilicity present with this linker.

While maintaining a desirable profile in the MDCK-mdr1 assay, which is predictive of brain penetration, gains were made in selectivity over our previously reported sulfonamide **7**. Fifteen compounds with over 100-fold selectivity (CB1:CB2 Ki vs CP55940) have been identified. These compounds, at least in part, were designed to increase the TPSA over currently known CB1 antagonists in hopes of limiting exposure to the CNS. They were found to have limited permeability (<1%) in the MDCK-mdr1 permeability assay, which serves as *in vitro* measure of CNS permeability. Based on data from the MDCK-mdr1 permeability assay, a set of compounds were chosen for both plasma and metabolic stability studies in human plasma and hepatic S9 fractions. These studies demonstrated that most compounds tested were at least as stable as **1** with low loss of the parent molecule even after two hours of incubation. Further evidence that some of these compounds do not penetrate the CNS was seen in an *in vivo* pharmacokinetics (PK) assay on compounds **17a**, **18a** and **18f**. Of these, **17a** and **18a** had little to no CNS penetration as demonstrated by a very low brain:plasma ratio. Further, both compounds demonstrated limited but clearly detectable oral absorption. Future studies will be aimed at improving the oral bioavailability of this class of compounds as well as exploring other scaffolds. Efficacy studies in disease models where these compounds may be useful are being planned as are more detailed PK studies to establish compound half-lives and dosing regimens.

In conclusion, a series of highly potent and selective CB1 antagonists were synthesized and evaluated leading to the identification of two compounds with limited brain penetration. These compounds will serve as templates for further refinement to enhance their oral bioavailability and to examine the role of peripheral CB1 receptors in various diseases such as obesity, liver fibrosis and diabetes.

## Experimental Section

### Compound synthesis and characterization

**Chemistry**—Reactions were conducted under N<sub>2</sub> atmospheres using oven-dried glassware. All solvents and chemicals used were reagent grade. Anhydrous tetrahydrofuran, dichloromethane, and N,N-dimethylformamide (DMF) were purchased from Aldrich and used as such. Unless otherwise mentioned, all reagents and chemicals were purchased from commercial vendors and used as received. Flash column chromatography was carried out on a Teledyne ISCO CombiFlash Companion system using RediSep Rf prepacked columns. Purity and characterization of compounds were established by a combination of HPLC, TLC, and NMR analytical techniques described below. <sup>1</sup>H and <sup>13</sup>CNMR spectra were recorded on a Bruker Avance DPX-300 (300 MHz) spectrometer and were determined in CHCl<sub>3</sub>-d or MeOH-d<sub>4</sub> with tetramethylsilane (TMS) (0.00 ppm) or solvent peaks as the internal reference unless otherwise noted. Chemical shifts are reported in ppm relative to the solvent signal, and coupling constant (J) values are reported in hertz (Hz). Thin-layer chromatography (TLC) was performed on EMD precoated silica gel 60 F254 plates, and spots were visualized with UV light or I<sub>2</sub> detection. Low-resolution mass spectra were obtained using a Waters Alliance HT/Micromass ZQ system (ESI). All test compounds were greater than 95% pure as determined by HPLC on an Agilent 1100 system using an Agilent Zorbax SB-Phenyl, 2.1×150 mm, 5 μm column with gradient elution using the mobile phases (A) H<sub>2</sub>O containing 0.05% CF<sub>3</sub>COOH and (B) Methanol. A flow rate of 1.0 mL/min was used.

**1-{{5-(4-Chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-1H-pyrazol-3-yl}carbonyl}-4-phenylpiperidine-4-carboxylic acid (10)**: A 2 M solution of oxalyl chloride in dichloromethane (3 eq., 0.19 mL, 0.377 mmol) was added to 5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-1H-pyrazole-3-carboxylic acid (**22**) (1 eq., 48 mg, 0.126 mmol) in dichloromethane (5 mL). Next, 2 drops of anhydrous N,N-dimethylformamide was added

and the reaction was stirred for 2 h. The reaction was concentrated *in vacuo*. The reaction mixture was dissolved in dichloromethane (5 mL). Triethylamine (3 eq., 0.05 mL, 0.377 mmol) and 4-carboxy-4-phenylpiperidin-1-ium chloride (**23**) (1.5 eq., 45.7 mg, 0.189 mmol) was added and the reaction was stirred for 16 h. The reaction was concentrated *in vacuo*. The crude reaction material was then purified by silica gel column chromatography using 0–10% methanol/dichloromethane with 1% acetic acid to yield pure desired product (**10**) (48 mg, 67%). <sup>1</sup>H NMR (300 MHz, CHLOROFORM-*d*) δ ppm 1.87 – 2.09 (m, 2 H), 2.15 (s, 3 H), 2.61 (t, *J*=16.18 Hz, 2 H), 3.21 (t, *J*=12.03 Hz, 1 H), 3.47 (t, *J*=11.94 Hz, 1 H), 4.26 (d, *J*=13.61 Hz, 1 H), 4.57 (d, *J*=13.56 Hz, 1 H), 7.05 (d, *J*=8.34 Hz, 2 H), 7.12 – 7.45 (m, 10 H), [M + H]<sup>+</sup> 568.4.

### Calcium mobilization and radioligand displacement assays

Each compound was pharmacologically characterized using a functional fluorescent CB1 activated Gα<sub>q16</sub>-coupled intracellular calcium mobilization assay in CHO-K1 cells as has been described in our previous publications and apparent affinity (K<sub>e</sub>) values were determined.<sup>7</sup> Briefly, CHO-K1 cells were engineered to co-express human CB1 and Gα<sub>q16</sub>. Activation of CB1 by an agonist then leads to generation of inositol phosphatase 3 (IP<sub>3</sub>) and activation of IP<sub>3</sub> receptors, which leads to mobilization of intracellular calcium. Calcium flux was monitored in a 96-well format using the fluorescent dye Calcein-4 AM in an automated platereader (Flexstation, Molecular Devices). The antagonism of a test compound was measured by its ability to shift the concentration response curve of the synthetic CB1 agonist CP55940 rightwards using the equation:

$$K_e = [\text{Ligand}] / [\text{DR} - 1]$$

where DR is the EC<sub>50</sub> ratio of CP55940 in the presence or absence of a test agent.<sup>14</sup>

Further characterization of select compounds was performed using radioligand displacement of [<sup>3</sup>H]SR141716 and equilibrium dissociation constant (K<sub>i</sub>) values were determined as has been described previously.<sup>7, 15</sup> Selectivity of these compounds at CB1 versus CB2 was also determined by obtaining K<sub>i</sub> values at either receptor using displacement of [<sup>3</sup>H]CP55940 in membranes of CHO-K1 cells over-expressing either receptor. Data reported are average values from 3–6 measurements.

## MDCK-mdr1 permeability assays

MDCK-mdr1 cells obtained from the Netherlands Cancer Institute were grown on Transwell type filters (Corning) for 4 days to confluence in DMEM/F12 media containing 10% fetal bovine serum and antibiotics as has been described previously.<sup>7</sup> Compounds were added to the apical side at a concentration of 3.16  $\mu\text{M}$  in a transport buffer comprising of 1X Hank's balanced salt solution, 25 mM D-glucose and buffered with HEPES to pH 7.4. Samples were incubated for 1 hr at 37°C and carefully collected from both the apical and basal side of the filters. Compounds selected for MDCK-mdr1 cell assays were infused on an Applied Biosystems API-4000 mass spectrometer to optimize for analysis using multiple reaction monitoring (MRM). Flow injection analysis was also conducted to optimize for mass spectrometer parameters. Samples from the apical and basolateral side of the MDCK cell assay were dried under nitrogen on a Turbovap LV. The chromatography was conducted with an Agilent 1100 binary pump with a flow rate of 0.5 mL/min. Mobile phase solvents were A, 0.1% formic acid in water, and B, 0.1% formic acid in methanol. The initial solvent conditions were 10% B for 1 minute, then a gradient was used by increasing to 95% B over 5 minutes, then returning to initial conditions. Data reported are average values from 2–3 measurements.

## *In vitro* stability testing

*In vitro* testing for metabolic stability was conducted in pooled samples of mixed gender human plasma from BioChemed Services, Winchester, VA and human mixed gender pooled hepatic S9 fraction supplied by Xenotech, LLC, Lenexa, KS. Identity of the donors was unknown.

For the hepatic S9 metabolism studies, all samples were tested at 10  $\mu\text{M}$  final concentration in a 1 ml volume containing 1 mg/ml S9. Samples were incubated in a buffer containing 50 mM potassium phosphate, pH 7.4 with 3 mM  $\text{MgCl}_2$  and a NADPH regeneration system comprising of NADP (1 mM), glucose-6-phosphate (5 mM) and glucose-6-phosphate dehydrogenase (1 unit/ml). Triplicate samples were incubated for 0, 15, 30, 60 and 120 min. Reactions were terminated by addition of 3 volumes of acetonitrile and processed as described for the MDCK-mdr1 assays but standard curves were prepared in blank matrix for each compound for quantitative assessment.

The plasma stability studies were conducted at 37°C in a volume of 1 ml plasma per sample. All compounds were tested at 10  $\mu\text{M}$  final concentration at 0, 30 and 60 min after a 5 min pre-incubation. Reactions were terminated by addition of acetonitrile and analyzed as described above.

## Evaluation of compounds *in vivo*

Male Sprague Dawley rats aged 7–8 weeks at time of dosing were acquired from Charles River Laboratories and were dosed by two routes: ip or oral. Oral doses were formulated in corn oil and ip doses were formulated in 1:1:18 ethanol:cremophor:saline, both at 10 mg/kg. Plasma and brain were taken from all rats at 1 hour post-dose. At 30 minutes post-dose, tail vein blood was collected only from rats dosed orally.

Samples were prepared and analyzed as follows: Plasma (50  $\mu\text{L}$ ) was mixed with 10  $\mu\text{L}$  of internal standard, reserpine (1  $\mu\text{g}/\text{mL}$ ), 10  $\mu\text{L}$  of acetonitrile, and 300  $\mu\text{L}$  of acetonitrile, vortexed, and centrifuged at 9000g for 5 minutes. Supernatant, (100  $\mu\text{L}$ ) was mixed with 900  $\mu\text{L}$  of 50:50 methanol:water in autosampler vials. For 30 minute plasma samples, the supernatant was injected without dilution. The left lobe of the brain was homogenized with 50:50 ethanol:water (3:1, v/v) using a Potter Elvehjem type homogenizer. Homogenate (50  $\mu\text{L}$ ) was mixed with 10  $\mu\text{L}$  of internal standard, reserpine (1  $\mu\text{g}/\text{mL}$ ), 10  $\mu\text{L}$  of acetonitrile,

and 300  $\mu$ L of acetonitrile, vortexed and centrifuged at 9000 g for 5 minutes. Supernatant was transferred to inserts and injected without dilution. Standards were prepared as above for each compound in blank plasma, blank liver homogenate, and blank brain homogenate. Standards used were within 15% of nominal, except for 20% at LOQ. Compounds for LC-MS/MS analyses were supplied at 1 mg/mL in methanol. The stock solutions were further diluted to  $\sim$ 100 ng/mL. The 100 ng/mL solutions were used to optimize the mass spectrometer for MRM transitions and mass spectrometer parameters. Infusion and flow injection optimization were also performed.

## Supplementary Material

Refer to Web version on PubMed Central for supplementary material.

## Acknowledgments

The authors would like to thank Ann Gilliam for performing the binding assays, Ms. Sherry Black and Ms. Purvi Patel for help with metabolic stability studies. We express our gratitude to the NIDA drug supply program for providing radiolabeled probes and to Dr. Brian Thomas for supplying the CB1 cells. This research was funded by research grants 1R21AA019740-01 and 1R03AA017514-01 to R. M. from NIAAA.

Exploration of different spacers

**Scheme 1.**Synthesis of compound **11**

**Reagents and conditions:** (a) 1) oxalyl chloride, DMF (cat.), dichloromethane, 2) **23**, triethylamine, dichloromethane; (b) (benzotriazol-1-yloxy)tris(dimethylamino)phosphonium hexafluorophosphate (BOP), triethylamine, ammonium chloride, THF.

**Scheme 2.****Synthesis of analogues of compound 11**

Reagents and conditions: (a) amine, BOP, triethylamine, THF; (b) 30% TFA in dichloromethane; (c) acetic anhydride, pyridine; (d) methanesulfonyl chloride, pyridine; (e) isocyanate, triethylamine, THF, rt or 40 °C.

**Scheme 3.**

Synthesis of compounds with different spacers and functional groups.

Reagents and conditions: (a) amine, BOP, triethylamine, THF; (b) 30% TFA in dichloromethane; (c) acetic anhydride, pyridine; (d) methanesulfonyl chloride, triethylamine, THF; (e) isocyanate, triethylamine, THF, rt; (f) ethyl chloroformate, triethylamine, THF; (g) 50% TFA in dichloromethane.

**Scheme 4.**

Synthesis of compounds with different spacers and functional groups continued.

**Reagents and conditions:** (a) sulfamide, dioxane, 90° C; (b) isocyanate, triethylamine, THF, rt.

**Table 1**Pharmacological assessment of compound **11** with rimonabant **1** and otenabant **2**.
