Background: Diabetes is one of the growing health problems worldwide, and scientists have been striving to find effective treatment methods. In this regard, chalcones have frequently been targeted by many researchers owing to their diverse biological activities.

Methods: Here, the Claisen–Schmidt condensation reaction was applied to synthesize five chalcone derivatives. The chalcone derivatives were evaluated for their relative antidiabetic activities in vivo using streptozotocin (STZ)-induced diabetic mice. Besides, the compounds were assessed for their reduction in postprandial hyperglycemia at 50 and 100 mg/kg dose levels against a standard drug, glibenclamide. In addition, the structure–activity relationship (SAR) was analyzed to determine the effect of structural modification in chalcones activity.

Results: A dose-dependent reduction in postprandial hyperglycemia was observed. The highest reduction in blood glucose level (BGL) was achieved by compound **3** at a dose of 100 mg/kg (39%). This was found to be even higher than glibenclamide (34.5%). In the STZ-induced diabetic animal model, all test compounds showed comparable efficacy with glibenclamide. The SAR analysis revealed that the incorporation of electron-donating groups at position 5 of the benzaldehyde ring and position 2 of the acetophenone ring is promising to increase the antihyperglycemic activities of chalcones.

Conclusion: The chalcone derivatives considered in this study could be used as potential lead compounds in the discovery of effective drugs to treat diabetes mellitus.

Keywords: antidiabetic, chalcone, diabetes mellitus, structure–activity relationship, streptozotocin, characterization, in vivo

Introduction

Diabetes mellitus is a metabolic disorder with various etiologies. The disease is marked by chronic hyperglycemia, which is associated with the disturbances of carbohydrate, protein and fat metabolism arising from defects in insulin secretion, action, or both.¹ The global diabetes prevalence has been steadily increasing over the past three decades.² According to the recent estimation by the International Diabetes Federation (IDF), there were 451 million people with diabetes mellitus in 2017 worldwide and traumatically, this number is expected to rise to 693 million by 2045.³

Being a global concern, several pharmacological and non-pharmacological diabetes treatment methods have been reported by different studies. In line with this, some drugs are already approved and commercially available, while some are under clinical trial.^{4,5} In this aspect, chalcones and their derivatives are considered as one of the promising future antidiabetic drugs and have been targeted by many researchers.^{6,7} Chalcones are

Graphical Abstract

one of the naturally found phytochemicals and are ubiquitous in various plants including the species of *Angelica*, *Glycyrrhiza*, *Humulus* and *Scutellaria*. Many of these plants are widely used as traditional remedies owing to their diverse pharmacological properties. Chalcones are also abundant in edible plants. Besides, they are taken as precursors during flavonoid biosynthesis. The basic chalcone chromophore contains a 1,3-diphenyl-2-propen-1-one structure where two aromatic rings are joined by a three-carbon unit that has an α , β -unsaturated carbonyl system.⁸ This chromophore can be found as either *trans* (E) or *cis* (Z) isomer, and several studies verified that the *E* isomer is more stable than the *Z* isomer.⁹ There are several reactive hydrogens on the basic chalcone structure. This opens opportunities for structural modification and the synthesis of a range of chalcone derivatives. Previous studies have documented that chalcone derivatives show various biological activities including antidiabetic,^{10–13} anti-neoplastic,^{11,14,15} anti-inflammatory,¹⁶ anti-malarial,¹⁷ antioxidant,^{16,18} anti-gout,¹⁹ hypolipidemic,¹³ anti-bacterial,^{16,20} and other related activities.^{9,21–23} In particular, studies on the antidiabetic activities of synthetic and natural chalcones (isolated from plants) showed promising activities on different target sites.²² With these aspects, metochalcone and sofalcone were recently approved as a choleric drug and an anti-ulcer agent, respectively. Furthermore, clinical trials using hesperidin methylchalcone for chronic venous lymphatic insufficiency and hesperidin trimethylchalcone for varicosis led to the relieving of symptoms, reached significant plasma

concentrations, and showed good-tolerance making them good drug candidates.^{21,24}

Despite the diverse studies conducted to find a long-lasting treatment method for diabetes, the signs of progress are challenged by the cost of production, ineffectiveness and affordability. Therefore, there is still a need for discovering and investigating new and effective potential drugs that are easily affordable by diabetic patients. In an effort made to find molecules with promising antidiabetic activities, five chalcone derivatives were synthesized in this study and their relative antidiabetic activities were investigated *in vivo*. In addition, the structure–activity relationship (SAR) was evaluated to view the association of structural modification and antidiabetic activity.

Materials and Methods

Chemistry

All chemicals and reagents used in this research were obtained from commercial suppliers and were of analytical grade. TLC analysis was performed on Silica-gel pre-coated plate (Merck, Germany). Silica gel packed (100–200 mesh size) column chromatography was used for the isolation and purification of the synthesized compounds. IR was recorded on FT-IR spectrometer (SHIMADZU, Japan). ¹H NMR, ¹³C NMR and DEPT-135 spectra were recorded on Bruker 400 MHz and 100 MHz spectrometers (Bruker, Germany). Melting points were determined using the Stuart melting point apparatus (SMP3, VENDOR) and were uncorrected. A glucometer with test strips (i-QARE

DS-W, Taiwan) was used to measure the blood glucose level of mice.

General Procedure for the Synthesis of Compounds

The synthesis of all the chalcone derivatives was achieved using Claisen–Schmidt condensation reaction (Scheme 1).²⁴ For each reaction, equimolar quantities of benzaldehyde derivatives (13 mmol) and acetophenone derivatives (13 mmol) were dissolved in 65 mL absolute ethanol in a 250 mL round-bottom flask equipped with a magnetic stirrer. Then, 60% aq. NaOH (40 mL) was added dropwise and the reaction mixture was stirred at room temperature. The progress of the reaction was monitored by TLC every 2 h using n-hexane: ethyl acetate (3:1) as mobile phase. After completion of the reaction, the mixture was neutralized with 2M HCl and then allowed to cool in an ice bath, whereby a yellow precipitate was formed. The reaction mixture was filtered using a vacuum system, and the resulting solid was then washed with cold water, dried and eluted over silica gel packed column chromatography using the same solvent system to get the target chalcone derivative (Table 1).

Synthesis of (E)-1-(2-Hydroxyphenyl)-3-(3-Methoxy-4-Hydroxy-5-Bromophenyl) Prop-2-En-1-One (Compound 1)

Yellow solid; yield 75%; m.p. 162–163 °C; R_f (n-hexane: ethyl acetate 3:1) 0.243; IR (KBr) (cm^{-1}) (Supplementary Figure S1): 3264 (O-H), 3101 and 3071 (C-H), 1675 (C=O), 1589 (C=C), 970 (E); ^1H NMR (400 MHz, CDCl_3) δ (ppm) (Supplementary Figure S2A and S2B): 7.94 (dd, $J = 8.1, 1.7$ Hz, 1H, 6'-H), 7.80 (d, $J = 15.3$ Hz, 1H, α -H), 7.66 (d, $J = 1.8$ Hz, 1H, 6-H), 7.52 (ddd, $J = 8.6, 7.2, 2.1$ Hz, 1H, 4'-H), 7.38–7.28 (m, 2H, 2-H, β -H), 7.11–7.02 (m, 1H, 3'-H), 6.97 (ddd, $J = 8.2, 7.1, 1.2$ Hz, 1H, 5'-H), 6.65 (s, 1H, 2'-OH), 4.01 (s, 1H, 4-OH), 4.00 (s, 3H, OCH_3);

Synthesis of (E)-1-(2,4-Dichlorophenyl)-3-(4-Hydroxy-3,5-Dimethoxyphenyl) Prop-2-En-1-One (Compound 4)

Yellow solid; yield 73.6%; m.p. 93–94 °C; R_f (n-hexane: ethyl acetate 3:1) 0.148; IR (KBr) (cm^{-1}) ([Supplementary Figure S11](#)): 3317 (O-H), 3117 and 3073 (C-H), 1651 (C=O), 1602 (C=C), 976 (E); ^1H NMR (400 MHz, CDCl_3) δ (ppm) ([Supplementary Figure S12A](#) and [S12B](#)): 7.47 (d, $J = 1.9$ Hz, 1H, 3'-H), 7.41 (d, $J = 8.2$ Hz, 1H, 6'-H), 7.36–7.30 (m, 2H, α -H, 5'-H), 6.95 (d, $J = 16.0$ Hz, 1H, β -H), 6.80 (s, 2H, 2,6-H), 3.95 (s, 1H, OH), 3.91 (s, 6H, 3,5- OCH_3); ^{13}C NMR (100 MHz, CDCl_3) δ (ppm) ([Supplementary Figure S13](#)): 192.74 (C=O), 147.56 (C- β), 147.34 (C-3, C-5), 138.08 (C-2'), 137.62 (C-4), 136.61 (C-1'), 132.22 (C-4'), 130.24 (C-6'), 130.11 (C-3'), 127.25 (C-5'), 125.66 (C-1), 124.02 (C- α), 105.75 (C-2, C-6), 56.38 (OCH_3); DEPT-135 δ (ppm) ([Supplementary Figure S14](#)): 147.56 (CH), 130.24 (CH), 130.11 (CH), 127.25 (CH), 124.02 (CH), 105.75 (CH), 56.38 (O- CH_3).

Synthesis of (E)-1-(2,4-Dichlorophenyl)-3-(5-Bromo-4-Hydroxy-3-Methoxyphenyl) Prop-2-En-1-One (Compound 5)

Yellow solid; yield 71%; m.p. 145–146 °C; R_f (n-hexane: ethyl acetate 3:1) 0.256; IR (KBr) (cm^{-1}) ([Supplementary Figure S15](#)): 3322 (O-H), 3140 and 3092 (C-H), 1656 (C=O), 1607 (C=C), 972 (E); ^1H NMR (400 MHz,

CDCl_3) δ (ppm) ([Supplementary Figure S16A](#) and [S16B](#)): 7.47 (d, $J = 1.9$ Hz, 1H, 3'-H), 7.42 (d, $J = 8.2$ Hz, 1H, 6'-H), 7.36 (d, $J = 2.0$ Hz, 1H, 6-H), 7.34–7.28 (m, 2H, 5'-H, α -H), 7.01 (d, $J = 1.9$ Hz, 1H, 2-H), 6.97 (d, $J = 16.0$ Hz, 1H, β -H), 6.45 (s, 1H, OH), 3.94 (s, 3H, OCH_3); ^{13}C NMR (100 MHz, CDCl_3) δ (ppm) ([Supplementary Figure S17](#)): 192.40 (C=O), 147.44 (C-3), 145.87 (C-2'), 145.50 (C- β), 137.38 (C-4), 136.89 (C-1'), 132.26 (C-4'), 130.33 (C-6'), 130.17 (C-3'), 127.42 (C-1), 127.32 (C-5'), 126.51 (C-6), 124.79 (C- α), 109.08 (C-2), 108.75 (C-5), 56.49 (OCH_3); DEPT-135 δ (ppm) ([Supplementary Figure S18](#)): 145.50 (CH), 130.33 (CH), 130.17 (CH), 127.32 (CH), 126.51 (CH), 124.79 (CH), 109.08 (CH), 56.49 (CH).

Biological Activities

Experimental Animals

Swiss albino mice weighing 25 ± 3 g and of age 6–8 weeks were obtained from the Department of Pharmacology, School of Pharmacy, College of Health Sciences, Mekelle University. The animals were housed in standard cages and maintained on a standard pelleted diet and water. After randomization into various groups and before initiation of the experiment, the mice were acclimatized to the animal house conditions (room temperature of 22 ± 3 °C, relative humidity of 50–60%, and 12 h light and 12 h dark cycle) for 7 days. Ethical clearance was obtained from Mekelle University, College of Health Sciences ethics committee. Besides, the guide for the care and use of laboratory animals was followed for the welfare and treatment of the laboratory animals.²⁵

Induction of Experimental Diabetes

Experimental mice were made diabetic by a single intraperitoneal injection of STZ. STZ was dissolved in 0.1M citrate buffer (pH 4.5) and a calculated amount of freshly prepared solution was injected into overnight fasted animals at a dose of 60 mg/kg body weight intraperitoneally.²⁶ The level of fasting blood glucose (FBG) of each animal was checked 72 hrs later using a glucometer by taking blood samples from the tail vein of the mice. The blood glucose level of each mouse was measured three to four times and those showing average blood glucose levels above 200 mg/dL were finally included in the experiment and named as STZ-induced diabetic mice.^{27,28}

Biological Assays

In vivo Acute Oral Toxicity Test

Oral acute toxicity of the test compounds was investigated using female Swiss albino mice. The mice were fasted for 4 hrs before administering test compounds. After checking the solubility profile of the test compounds at different dose levels, 5% DMSO was used as a vehicle which was prepared using distilled water. The test compounds were given orally in a sequential dose starting at a dose of 10 mg/kg. After observing for signs of toxicity for 48 hrs with special attention to the first 4 hrs, the next dose of 50 mg/kg was administered. Dosing continued up to 500 mg/kg, and their survival was followed up to 14 days. Acute toxicity signs like lacrimation, hair erection, blinking, urination, muscle weakness, sedation and convulsion, reduction in motor activity, diarrhea, coma and death were checked in test mice.²⁹

Oral Glucose Tolerance Test (OGTT) in Normal Mice

OGTT was performed using male Swiss albino mice. After overnight fasting (16 hrs), BGL of each mouse was checked, and those mice with blood glucose levels between 60 and 90 mg/dL were divided into twelve groups of six mice each. Mice of experimental groups took the solution of the synthetic compounds orally dissolved in 5% DMSO at a dose of 50 mg/kg and 100 mg/kg body weight. Animals of the negative control group took an equal amount of DMSO whereas animals of the positive control group took glibenclamide 10 mg/kg body weight orally. A glucose load (2.5 g/kg body weight) was given to each animal orally exactly after 30 minutes post-administration of the test sample/vehicle.¹² The blood glucose profile of each mouse was again determined at 0, 30, 60, 90 and 120 minutes post-administration of glucose using a glucometer. The BGL of each mouse was measured three to four times and the average value was taken. Food but not water was removed from cages during the experimentation.^{12,30}

Dose Optimization

Screening of the test compounds for hypoglycaemic activity was performed at two dose levels (50 mg/kg and 100 mg/kg body weight) in normal healthy mice with the OGTT. A dose that improved glucose tolerance analogous to the standard drug (glibenclamide) was selected for further studies.

In vivo Antidiabetic Activity

STZ-induced diabetic mice were weighed and randomly divided into seven groups of six mice per group per cage. Group 1 received vehicle (5% DMSO), serving as a diabetic control group. Group 2 received the standard drug, glibenclamide, serving as a positive control group. Groups 3–7 were treated with synthesized compounds (1–5) dissolved in DMSO, respectively.

The mice were made to fast overnight and the fasting serum glucose, day 0, levels were calculated. The individual test compounds were administered at a dose of 100 mg/kg per os daily for 21 days at a fixed time. The negative control group received the same volume of the vehicle, whereas the positive control group received glibenclamide at a dose of 10 mg/kg body weight.

During the study, blood samples were taken from all mice on days 0, 7, 14 and 21, and percentage reduction in FBG was calculated. Blood samples were taken three to four times from the tail vein of each mouse on each day and the average value was determined. Glibenclamide was used as a reference drug in the determination of the in vivo antidiabetic activity of the synthesized compounds.

Data and Statistical Analysis

Measurements were made in quintuplicate ($n = 6$) unless otherwise mentioned and data were expressed as mean \pm SEM. One-way analysis of variance (ANOVA) followed by Tukey Post-Hoc test was used to determine the significant differences between groups. Differences were considered to be significant at $p \leq 0.05$. All the statistical analysis was conducted using SPSS-software (version 22). GraphPad prism version 9.1.2 was used for drawing graphs, and MS Excel 2016 was used for calculating AUC.

Results and Discussion

Chemistry

Scheme 1 shows the general synthesis procedure of the target chalcone derivatives. Briefly, compounds 1–5 were synthesized through base-catalyzed Claisen–Schmidt condensations using acetophenones substituted at position 2 or 4 or 2 and 4 and appropriately substituted benzaldehyde derivative. The identities of the compounds were confirmed using IR and several NMR spectral data that agreed with the proposed structures (Supplementary data).

Biological Activities

Bioassay Tests

The acute oral toxicity test was conducted to assess the acute lethal, physical and behavioral changes in response to the oral administration of the newly synthesized compounds. The chalcones were administered in a sequential dose starting from 10 to 500 mg/kg, and the weight of each mouse was recorded before and after receiving treatment. Survival was followed up to 14 days, and no mice showed signs of toxicity. Besides, no death was recorded during the follow-up period. Interestingly, there was no significant difference in the weight of the mice before and after treatments, which signifies that the median lethal dose (LD₅₀) of each of the test compounds was greater than 500 mg/kg.

The blood glucose-lowering effect of each chalcone derivative was tested at 50 and 100 mg/kg dose levels, and their effect on postprandial BGL in normal mice is shown in Table 2. The concentration of blood glucose in mice was measured at six time points, including immediately before administration of the test compounds (–30 min), immediately before glucose load (0 min) and at 30, 60, 90 and 120 min post-administration of glucose. The area under the curve (AUC) of each group was determined by plotting BGL against time, and it was used to determine the overall percentage of lowering in postprandial (post-glucose load) hyperglycemia. The results of AUC were used to compare the test compounds with each other, with the positive control group and the vehicle-treated group. All the test compounds showed significant changes in BGL at both dose levels compared to the negative control group (Figure 1A and B) (Table 2). In all the groups, the peak blood glucose level was seen 30 min post-administration where glibenclamide and the test compounds started to show a significant change in BGL. The highest percent reduction (39%) was seen in mice treated with compound 3 at a dose of 100 mg/kg. This value was even higher than the percent reduction achieved by glibenclamide (34.5%). Mice treated with compounds 1, 2, 4 and 5 showed 25.2, 15.4, 23.6 and 10.7% reductions at a dose of 50 mg/kg, and 34.3, 22.5, 32.5, and 25.4% reductions at a dose of 100 mg/kg, respectively (Tables 2 and 3).

It is evident from Table 3 that the improvements in postprandial hyperglycemia were found to be dose-dependent in all the test compounds. The highest dose-dependent effect was observed for compounds 3 and 4,

while the lowest dose-dependent effect was observed for compound 2.

Table 3 presents the percent reduction in postprandial hyperglycemia of the test compounds at each time point. Once again, compound 3 showed the highest reduction at a dose of 100 mg/kg at each time point, while compounds 1 and 4 showed a reduction comparable to glibenclamide (10 mg/kg). In contrast to glibenclamide, which showed its peak reduction (39.74%) at 120 min post-administration of glucose, all the test compounds showed their highest reduction in BGL at 60 min post-administration of glucose. These findings indicate that the compounds could be primary choices when there is a need for rapid reduction in BGL.

The comparison of test compounds revealed that the postprandial hyperglycemia reductions of compounds 1, 3, and 4 were significantly different from those of compounds 2 and 5 but not with each other at similar dose levels. At a dose of 100 mg/kg, the test compounds showed significant improvements in postprandial glucose tolerance comparable to glibenclamide and, hence, were taken for further antidiabetic activity study using STZ-induced diabetic mice.

The relative long-term effect of the chalcone derivatives on BGL was tested in vivo using STZ-induced diabetic mice. The test compounds and the standard drug were administered daily for 21 days at a fixed time after induction of diabetes. BGL was measured on days 0, 7, 14, and 21 at the same time and the results are shown in Table 4. Both glibenclamide and the test compounds showed significant reductions in BGL on days 7, 14 and 21 compared to the diabetic control group. On each day, all test compounds showed a comparable reduction in fasting BGL compared to the standard drug (glibenclamide), and the highest effect was seen on day 21. By comparison, compound 3 was found to show the highest antidiabetic activity (56.6% reduction) followed by 1 (51.3% reduction). Furthermore, compounds 2, 4 and 5 showed significant antidiabetic activities after 21 days of treatment and showed fasting BGL reductions of 46.6, 51.1, and 50.8%, respectively. Glibenclamide (10 mg/kg) showed a 57.2% reduction, and this value was not significantly different from those of the test compound (100 mg/kg). The test compounds also did not show significant variation with each other in reducing fasting BGL in STZ-induced diabetic mice.

The effects of the synthesized chalcone derivatives on the bodyweight of STZ-induced diabetic mice were also

Table 2 Effect of Test Compounds in Postprandial Hyperglycemia Post-Glucose Load in Normal Mice

Notes: Each value represents mean ± S.E.M, n=6 for each group. *p<0.05, **p<0.01, ***p<0.001, “.” sign shows percent ‘reduction’ *, ***, statistical significance as compared to the negative control group.

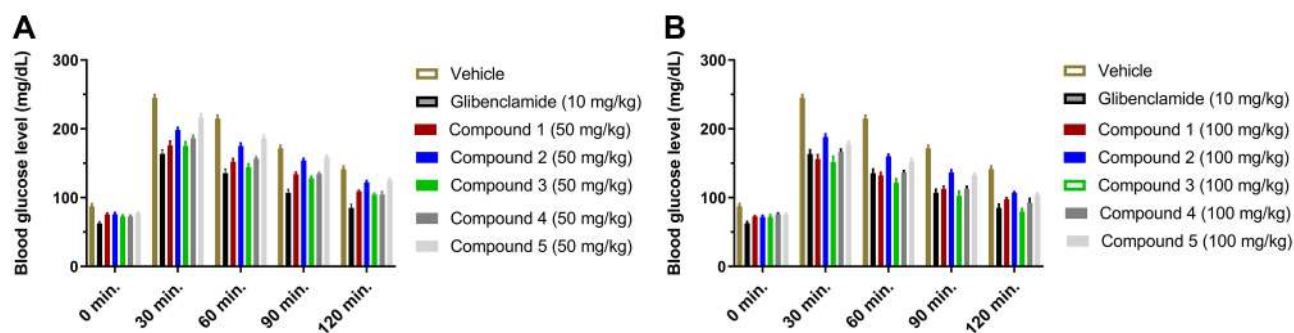

Figure 1 (A) Comparative inhibitory effect of the synthesized compounds in postprandial hyperglycemia post-glucose load in normal mice at a dose of 50 mg/kg. (B) Comparative inhibitory effect of the synthesized compounds in postprandial hyperglycemia post-glucose load in normal mice at a dose of 100 mg/kg.

evaluated and the results are given in Table 5. Daily oral administration of test compounds for 21 days at 100 mg/kg dose showed improvements in body weight. Compared to the diabetic control group that showed significant weight reduction (10.2%), glibenclamide increased the body-weight of the mice by about 11%, whereas compounds 1, 2, 3, 4 and 5 increased body weight by 6.1, 3, 10.3, 6 and 8.1%, respectively. The change in body weight caused by each of the rest test compounds was not significantly different from that of glibenclamide. Compound 2 was an exception in this regard since it showed a significant body weight reduction (4.8%). Likewise, compound 3 showed a weight gain by 0.3%.

SAR of the Synthesized Compounds for Their Antidiabetic Activity

The structural variation of the synthesized chalcones brought significant variation in their antidiabetic activities (Figure 2, Table 1). Compounds 2 and 3, which differ only on the type of substituents at positions 2' and 4', showed a significant difference in reducing postprandial hyperglycemia. The former showed 15.4 and 22.5%, while the latter showed 27.7 and 39% reduction of postprandial hyperglycemia at doses of 50 mg/kg and 100 mg/kg, respectively. These findings indicated that the presence of a hydroxyl group at 2' position improved glucose tolerance. This justification could also be applicable to the

Compound 5	24.77 ± 0.84	24.38 ± 0.82	24.25 ± 0.98	24.50 ± 0.72	+8.1%	−1.1%

Notes: Values are mean ± SEM, n=6, “+” percent increase, “-” percent decrease, DC- diabetic control, **P<0.01, ***P<0.001.

higher activity observed for compound 1 over compound 5 at similar dose levels.

Furthermore, a comparison of compounds 4 and 5 revealed that substitution of a methoxy group at position 5 by bromine resulted in a significant reduction in anti-hyperglycemic activity, from 23.6% to 10.7% at a dose of 50 mg/kg and from 32.5% to 25.4% at a dose of 100 mg/kg (Table 2). These results show that incorporation of an electron-donating group at that position is essential to maximize the anti-hyperglycemic activity of chalcones.

In contrast, changing the hydroxyl group from ortho to para position and adding bromine at position 5' on the benzaldehyde ring did not bring a significant change in reducing postprandial hyperglycemia (Table 3). This was observed by comparing compounds 1 and 2 with compounds 3 and 5, respectively. Likewise, changing the position and type of substituents in the aromatic rings did not show a significant difference in reducing fasting glucose levels in STZ-induced diabetic mice (Table 4).

Conclusion

Five chalcone derivatives were synthesized using the Claisen–Schmidt condensation reaction. The compounds were obtained with high purity and good yield (71–81.5%) and their structure was confirmed using IR, ¹H NMR, ¹³C NMR and DEPT-135 spectroscopic techniques. The OGTT model was carried out using normal mice, and the results showed that compound 3, at a dose of 100 mg/kg body weight, was highly active in reducing postprandial hyperglycemia (39%) compared to glibenclamide (34.5%) and the rest test compounds. At the same dose level, compounds 1 and 4 (34.3% and 32.5%, respectively) showed comparable efficacy with glibenclamide. In contrast, compounds 5 (25.4%) and 2 (22.5%) were relatively less effective in reducing postprandial hyperglycemia. In the STZ-induced diabetes model, all the test compounds showed comparable antidiabetic activity with each other and with glibenclamide on each day as compared to the diabetic control group. The antidiabetic activity in terms of the percent reduction in fasting BGL was in the order of compound 3 (56.6%) > compound 1 (51.3%) > compound 4 (51.1%) > compound

Figure 2 Chemical structure of the synthesized compounds (1–5).

5 (50.8%) > compound **2** (46.6%). Glibenclamide reduced BGL by 57.2%. In general, our results indicated that all the test compounds could be potential lead compounds in the discovery of potent and effective drugs for the treatment of diabetes mellitus.

Acknowledgment

The researchers are very grateful to Dr. Gomati (Ph.D. in Phytochemistry, Mekelle University, Ethiopia) for her unlimited help in arranging the purchasing process of chemicals required for the synthesis. Our sincere appreciation also goes to all beloved family of Welday, especially to Tsega Welday, who helped us by investing their money and precious time in searching and buying chemicals. In addition, the researchers acknowledge Addis Ababa University and Addis Pharmaceutical Factory for

providing NMR and IR services, respectively. This work is done under Mekelle University as part of MSc thesis. This study was Semere Welday's part of MSc work.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Drug Design, Development and Therapy

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also

been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/drug-design-development-and-therapy-journal>
