

1 **Diabetes-related lower-extremity complications are a leading cause of the global burden**  
2 **of disability**

3 **Short Title:** Diabetic leg complications a leading cause global disability

4

5 Globally ~435 million people have diabetes (1), with 19-34% (~83-148 million) of those  
6 estimated to develop foot ulcers in their lifetime (2). Foot ulcers are typically precipitated by  
7 other diabetes-related lower-extremity complications (DRLECs) including peripheral  
8 neuropathy and peripheral vascular disease (2, 3). Collectively, DRLECs are a leading cause  
9 of infection, hospitalisation and amputation outcomes (2-5); yet, these outcomes are readily  
10 preventable with evidence-based DRLEC care (6, 7). This suggests the burden caused by  
11 DRLECs is a large, yet reducible, cause of the global burden of disease.

12

13 Burden of disease is measured in disability-adjusted life-years (DALYs) (8). One DALY  
14 represents one year of healthy life lost (8). DALYs are estimated by summing the years of  
15 life lost (YLLs) due to premature mortality, and years lived with disability (YLDs) (1, 8).  
16 YLLs are estimated by multiplying the number of deaths from a cause, by the years lost  
17 between the age at death from that cause and the longest normal life expectancy age (8);  
18 YLDs are estimated by multiplying the prevalence of a cause, by a disability weight that  
19 reflects the severity of that cause (1).

20

21 The Global Burden of Disease Study (GBD) has published global YLD, YLL and DALY  
22 estimates for >300 disease and injury causes and >2,600 sequelae in several iterations over  
23 the last decade (GBD2010-GBD2016) (1, 8, 9). Of most interest to the global diabetes  
24 community were ongoing estimates for “diabetes mellitus” and “chronic kidney disease  
25 (CKD) due to diabetes mellitus” (1, 8, 9). However, estimated YLDs, YLLs and DALYs for

26 DRLECs remained hidden within the aggregated “diabetes mellitus” estimates presented in  
27 all these GBD publications, except for the GBD2015 YLD publication (1, 8, 9).

28

29 The GBD2015 YLD publication presented disaggregated findings for “diabetes mellitus” in  
30 three summary sequelae: “uncomplicated diabetes”, “vision loss due to diabetes”, and  
31 “neuropathy and other complications of diabetes” (1). According to GBD2015 methodology,  
32 “neuropathy and other complications of diabetes” consisted of a total of four specific  
33 sequelae, i.e. those with diagnosable neuropathy: i) only, “diabetic neuropathy”; ii) and  
34 current foot ulcer, “diabetic foot due to neuropathy”; iii) and leg amputation with prosthetic  
35 limb, “diabetic neuropathy and amputation with treatment”; iv) and leg amputation without  
36 prosthetic limb, “diabetic neuropathy and amputation without treatment (1). The last three of  
37 these four specific sequelae are exclusively DRLECs, with perhaps “diabetic neuropathy” the  
38 only exception (2,3).

39

40 However, GBD2015 goes on to define “diabetic neuropathy” as being diagnosed via  
41 “validated neuropathy screening, vibration perception threshold test, nerve conduction  
42 velocity, (or) clinical exam only” in people with “pain, tingling and numbness in arms, legs,  
43 hands or feet” (1). That being the case, we suggest that not only do peripheral neuropathies  
44 make up >75% of all diabetic neuropathy cases anyway (10), but the GBD2015 publication is  
45 only referring to the diabetic peripheral neuropathies in its definition of “diabetic neuropathy”  
46 (1). Whilst, diabetic peripheral neuropathies can present in the upper extremity after the  
47 lower extremity, it nearly exclusively disables the lower extremity (10). Because it is defined  
48 by three exclusively and one nearly exclusively DRLEC sequelae (2,3), we suggest that the  
49 GBD2015 summary sequelae of “neuropathy and other complications of diabetes” (1) is  
50 suitable to use for the purposes of reporting the estimated global YLD burden caused by

51 DRLECs. Thus, we report the GBD2015 “neuropathy and other complications of diabetes”  
52 YLD publication findings as DRLECs findings to provide estimates of the magnitude of the  
53 global disability burden of DRLECs and compare these estimates to other causes for the first  
54 time (1).

55

56 First, GBD2015 published that diabetes affected 435 million people (1) (~5.9% of the 7.38  
57 billion global population), ranking it 17<sup>th</sup> of all causes for prevalence (1). When diabetes was  
58 disaggregated into summary sequelae, we estimate DRLECs affected 159 million people  
59 (~2.2%) (1). As such, DRLECs would rank within the top-40 causes for prevalence; lower  
60 than CKD (~4.4%), but higher than ischaemic heart disease (IHD) (~1.5%), and  
61 cerebrovascular disease (CVD) (~0.6%) (1).

62

63 Second, GBD2015 published that diabetes accounted for 33.4 million YLDs, ranking it 6<sup>th</sup> of  
64 all causes for YLDs (1). When diabetes was disaggregated, we estimate DRLECs accounted  
65 for 61% (20.5 million) of YLDs due to diabetes, equalling 2.6% of all 792 million global  
66 YLDs (1). YLDs due to DRLECs would rank within the top-10 causes of global YLDs;  
67 higher than CKD (8.2 million), IHD (7.3 million), and CVD (6.5 million) (Figure 1) (1).

68

69 Third, GBD2015 published that diabetes had the third largest increase (32.5%) of the top-30  
70 level 3 (disease and injury) YLD causes between 2005 and 2015 (1). When diabetes was  
71 disaggregated, we estimate DRLECs would rank as the second largest increase (35.6%) of the  
72 top-30 causes of global YLDs; higher than IHD (30.2%), CKD (23.8%), and CVD (20.7%)  
73 (1).

74

75 After interrogating the GBD2015 YLD publication, we estimate that the disability burden  
76 caused by DRLECs would rank within the top-10 leading causes of the global disability  
77 burden (1). Whilst there is a possibility that our estimated DRLEC disability burden may  
78 contain a small proportion attributable to upper extremity diabetic peripheral neuropathies,  
79 we note we were unable to include additional DRLECs in our YLD estimates as they were  
80 not disaggregated in GBD2015, such as diabetes-related “peripheral vascular disease” (1).  
81 Thus, if anything our DRLEC estimates are likely to be an underestimate. With DRLECs also  
82 resulting in mortality rates worse than many cancers (2,4,5), we recommend future GBD  
83 publications should present YLD, YLL and DALY estimates for “lower-extremity  
84 complications due to diabetes” to highlight the potentially significant overall global burden of  
85 DRLECs to policymakers, as they do for “chronic kidney disease due to diabetes” (1). In the  
86 meantime, these findings highlight the need for policymakers to prioritise policies that  
87 improve evidence-based care for people with DRLEC (6, 7), and thus, potentially reduce a  
88 large cause of the global burden of disease.
