Abstract

We give a formal account of a calculus for modeling service-based systems, suitable to describe both service composition (orchestration) and the protocol that services run when invoked (conversation). The calculus includes primitives for defining and invoking services, for isolating conversations between clients and servers, and for orchestrating services.

The calculus is equipped with a reduction and a labeled transition semantics related by an equivalence result. To hint how the structuring mechanisms of the language can be exploited for static analysis we present a simple type system guaranteeing the compatibility between client and server protocols, an application of bisimilarity to prove equivalence among services, and we discuss deadlock-avoidance.

1 Introduction

Enterprise application integration, either to reuse legacy code, or to combine third-party software modules, has long been tackled by several middleware proposals, namely using message brokers or workflow management systems. As the popularity of using the Web increased, traditional middleware was forced to provide integration across companies over it. The technologies developed lay in the concept of *Web service*: a way of exposing (to the Web) the functionalities performed by internal systems and making them discoverable and accessible through the Web [1]. Web services emerged as the main paradigm to program applications on the Web. An important reason is that currently available standards [2, 3, 7, 11] allow to easily orchestrate different services (distributed and belonging to different or-

ganizations) to achieve required business goals, maximizing interoperability.

While standards and programming tools are continuously improving, the formal bases of Service Oriented Computing (SOC) are still uncertain: there is an urgent need for models and techniques allowing the development of applications in a safe manner, while checking that systems provide the required functionalities. These techniques should be able to deal with the different aspects of services (seen in the abstract context of global computing [9]), including their dynamic behavior.

Process calculi are an important tool to give precise semantics to system specifications, and they come equipped with a rich toolbox of analysis techniques (type systems, bisimulations, ...). Nevertheless, how to use process calculi to model service oriented systems is not yet clear. When defining a calculus for SOC, different aspects influence the choice of primitives and of their behavior, and a careful trade-off between expressiveness and suitability to analysis should be found. Our main concerns have been:

Expressiveness of the language: the calculus should be able to express in a direct way the different kinds of interactions that characterize SOC: invocations of services, client-server conversations and interactions among different client-server pairs. We use three different classes of operators to this end: services, sessions, and streams. We show via examples that these are enough to model various kinds of SOC scenarios. We stress in particular the importance of the third kind of interaction, which is the heart of orchestration. Other constructs such as, e.g., tuple spaces or shared memory would be as expressive as streams, but would be difficult to analyze.

Expressiveness of the analysis: the elements to be analyzed should correspond to explicit elements in the calculus. Concerning the classes above, service definition is fundamental to speak about service availability. It also allows easy extensions for service discovery based on quality of service. Sessions instead allow to analyze client-server compatibility and to study behavioral-based service discovery. Other mechanisms, such as BPEL correlation sets [2], would make these analyses more complex, since they rely on runtime values for determining the communication patterns.

Computability of the analysis: static analysis should be decidable, possibly also efficient to compute. Thus the allowed communication patterns should be constrained whenever this does not destroy expressiveness. In our calculus streams and sessions are static, and the dynamism is concentrated in service invocation. To stress the effect of these considerations on the design decisions, we give some “proof of concept” analyses to illustrate how to exploit the features of the calculus.

This paper proposes SSCC (Stream-based Service Centered Calculus), a calculus for modeling service-based systems, inspired by SCC [4] and Orc [13, 16], and developed with the above considerations in mind.

We introduced SSCC after having tried to use SCC and failed. While proposing interesting concepts, like sessions, and featuring services as first class entities, SCC looks not fully adequate (at least as presented in [4]) for service composition. In fact the only way for a session to interact with other client-server pairs is the **return** primitive, and the functional style of invocation is not adequate for modeling complex patterns of interactions such as van der Aalst workflow patterns [20]. To overcome these problems we introduced streams and we allowed non persistent service invocations. This enhances the expressiveness of the calculus and makes it easier to program.

Another source of inspiration was Orc [16], a basic programming model for orchestration of Web services. Here a few coordination constructs are used to model the most common patterns, and a satisfying expressiveness is claimed by presenting a formalization of all van der Aalst workflow patterns [8]. However, in order to model the more challenging patterns, special sites (the basic computation entity in Orc) are required, acting e.g. as semaphores. This is a coordination concern, and in our opinion should be addressed within the language. Thus we introduced more basic mechanisms to tackle all the coordination concerns inside the calculus (most of Orc operators can be expressed as macros in our model). Also, we introduced conversations, which are absent in Orc, to model service behavior (Orc leaves this unspecified). It is thus not possible to develop for Orc analysis techniques to ensure, e.g., deadlock freedom, as this would require analyzing the behavior of the sites involved.

Among the calculi, π -calculus (and its variants) has been

frequently used in SOC. However we claim that general purpose concurrent calculi are not suitable for our aims, since the different communication patterns are mixed, and most of the interesting properties not reflected in the term. Thus these calculi do not satisfy the requirements above. Different proposals used types, e.g. session types [10, 12, 19, 22], to solve this problem, but since they allow free π -calculus communications the analysis is difficult. We consider our proposal as some kind of tamed π -calculus, with a good trade-off between expressiveness for SOC systems and suitability to analyze SOC-related properties.

Other calculi tailored for SOC exist, and we briefly compare with them.

Carbone et al. [6] aim at capturing the principles behind Web service based business processes. A global description of communication behavior needs to be complemented by an “endpoint-based” description of each participant to the protocol, a projection of the global scenario. We are at the same abstraction level of the endpoint calculus, but this one relies on shared memory and general communication mechanisms, making it more difficult to analyze.

Lapadula et al. introduce C \ddot{O} WS [15], a process calculus for Web service orchestration. For isolating interactions between partners, C \ddot{O} WS uses message correlation, the approach of WS-BPEL [2]. Our approach based on sessions is dual to this, and ensures more structured communication.

Busi et al. [5] propose SOCK, a process calculus inspired in Web services specifications. SOCK is composed by different layers, taking care of particular aspects such as service behavior, state, and interactions between different sessions of the same service. SOCK also uses message correlation to define client-server interactions. SOCK is quite complex since it closely follows current standards in SOC technologies, but we want to explore more in depth the semantic issues of SOC without the additional complexity needed to model industrial standards.

Proofs for the results presented herein, and an encoding of van der Aalst workflow patterns [20], can be found in a technical report [14].

2 A motivating example

We start with a simple process to deliver the price for a given date at a given hotel.

```
(date) <query-the-hotel-db>.price
```

The parentheses in (date) indicate the reception of a value, and an identifier alone, as in price, means publishing a value. Hotel bologna may turn this conversation into a service, by writing:

```
bologna  $\Rightarrow$  (date) <query-the-hotel-db>.price
```

A client is supposed to meet the expectations of the service by providing a date and requesting a price:

```
bologna  $\Leftarrow$  31Jul2007.(price) <use-price>
```

When the service provider (\Rightarrow) and the service client (\Leftarrow) get together, by means, e.g., of parallel composition, a *conversation* takes place, and values are exchanged in both directions.

Now suppose that a broker comes to the market trying to provide better deals for its clients. The broker asks prices to three hotels that it knows of, waits for two results, and publishes the best offer of the two. Calling the services for a given date is as above:

```
bologna  $\Leftarrow$  date.(price1) ... |
azores  $\Leftarrow$  date.(price2) ... |
lisbon  $\Leftarrow$  date.(price3) ...
```

In order to collect the prices, we introduce a *stream* constructor, playing the role of a *service orchestrator*. The various prices are fed into the stream; a different process reads the stream. We write it as follows.

```
stream
bologna  $\Leftarrow$  date.(price1).feed price1 |
azores  $\Leftarrow$  date.(price2).feed price2 |
lisbon  $\Leftarrow$  date.(price3).feed price3
as f in
f(x).f(y).<publish-the-min-of-x-and-y>
```

To write price1 into a stream we use the syntax **feed** price1. To read a value from stream f we use f(x).<use-x>. Writing is an anonymous operation (feeds to the nearest enclosing stream), whereas reading is named. The above pattern is so common that we provide a special syntax for it, inspired by **Orc** (the various abbreviations used in this paper are summarized in Figure 7).

```
(call bologna(date) |
call azores(date) |
call lisbon(date)) >2
x y > <publish-the-min-of-x-and-y>
```

To complete the example we rely on a min service, chaining the first two answers, and publishing the result.

```
broker  $\Rightarrow$  (date).(
(call bologna(date) |
call azores(date) |
call lisbon(date)) >2
x y > call min(x,y) >1 m > m)
```

Notice that a client interacts with the broker as if it was interacting with a particular hotel. The downside is that the client does not know which hotel offers the best price; we leave it to the reader to adapt the example as required.

Further examples can be found in Section 4.

3 The SSCC calculus

This section presents the syntax and the operational semantics of SSCC.

Processes are built using three kinds of identifiers: *service names* ranged over by a, b, x, y, \dots , *stream names* ranged over by f, g, \dots , and *process variables* ranged over

$P, Q ::=$	<i>Processes</i>
$P Q$	Parallel composition
$(\nu a)P$	Name restriction
$\mathbf{0}$	Terminated process
X	Process variable
$\text{rec } X.P$	Recursive process definition
$a \Rightarrow P$	Service definition
$a \Leftarrow P$	Service invocation
$v.P$	Value sending
$(x)P$	Value reception
$\text{stream } P \text{ as } f \text{ in } Q$	Stream
$\text{feed } v.P$	Feed the process' stream
$f(x).P$	Read from a stream
$u, v ::=$	<i>Values</i>
a	Service name
unit	Unit value

Figure 1. The syntax of SSCC

by X, Y, \dots . The grammar in Figure 1 defines the *syntax of processes*.

The first five cases of the grammar introduce standard process calculi operators: parallel composition, restriction (only for service names), the terminated process, and recursion. We then have two constructs to *build services*: definition (or provider) and invocation (or client). Both are defined by their name a and protocol P . Service definition and service invocation are symmetric (differently from [4]). *Service protocols* are built using value sending and receiving, allowing bidirectional communication between clients and servers. Finally there are the three constructs for *service orchestration*, which constitute the main novelty of SSCC. The stream construct declares a stream f for communication from P to Q . P can insert a value v into the stream using $\text{feed } v.P'$, and Q can read from there using $f(x).Q'$. Notice that stream names cannot be communicated, thus they model static channels.

Processes at runtime exploit an extended syntax: the interaction of a service definition and a service invocation produces an active session. Also, values in the stream are stored together with the stream definition. We introduce a fourth kind of identifier: *session names*, use r, s, \dots to range over them, and use n, m, \dots to range over both session and service names. The grammar in Figure 2 defines the *syntax of runtime processes*.

We use $r \bowtie P$ to denote both $r \triangleleft P$ and $r \triangleleft P$, and we assume that when multiple \bowtie appear in the same rule they are instantiated in the same way, and that if \bowtie appears too then it denotes the opposite instantiation. The constructor $\text{stream } P \text{ as } f \text{ in } Q$ in Figure 1 is an abbrevia-

$P, Q ::=$	<i>Processes</i>
...	as in Figure 1
$r \triangleright P$	Server session
$r \triangleleft P$	Client session
$(\nu r)P$	Session restriction
$\text{stream } P \text{ as } f = \vec{v} \text{ in } Q$	Stream with values

Figure 2. The run-time syntax of SSCC

$\mathcal{C}[] ::=$	\bullet $\mathcal{C}[] Q$ $P \mathcal{C}[]$
	$(\nu n)\mathcal{C}[]$ $\text{stream } \mathcal{C}[] \text{ as } f = \vec{v} \text{ in } Q$
	$\text{stream } P \text{ as } f = \vec{v} \text{ in } \mathcal{C}[]$ $r \bowtie \mathcal{C}[]$
$\mathcal{D}[], [] ::=$	$\mathcal{C}'[] \mathcal{C}''[]$ $\text{stream } \mathcal{C}'[] \text{ as } f = \vec{v} \text{ in } \mathcal{C}''[]$

Figure 4. Active and double contexts

tion of stream $P \text{ as } f = \langle \rangle$ in Q in Figure 2.

Streams can be considered either ordered or unordered. An unordered stream is a multiset, while an ordered one is a queue. In most cases the difference is not important. We write $w :: \vec{v}$ for the stream obtained by adding w to \vec{v} , and $\vec{v} :: w$ for a stream from which w can be removed. In the latter case \vec{v} is what we get after removing w . The semantics that we present can deal with both ordered and unordered streams, by just changing the definition of ‘::’.

As for bindings, name x is bound in $(x)P$ and in $f(x).P$; name n is bound in $(\nu n)P$; stream f is bound in $\text{stream } P \text{ as } f \text{ in } Q$ with scope Q ; and process variable X is bound in $\text{rec } X.P$. All bound identifiers are α -convertible. Notation $\text{fn}(P)$ denotes the set of free (service or session) names in P . Similarly, $\text{bn}(P)$ is the set of bound names. We require processes to have no free process variables.

SSCC exploits a standard structural congruence, simply adding to that of the π -calculus axioms that deal with scope extrusion for sessions and streams.

Definition 3.1 (Structural congruence) *The rules in Figure 3, together with the commutative monoid rules for $(P, |, \mathbf{0})$, inductively define the structural congruence relation on processes.*

Interactions can happen in different active contexts. Since all our interactions are binary, we introduce also two-holes contexts, which we call double contexts. The grammar in Figure 4 generates *active and double contexts*. Applying a double context to two processes P_1 and P_2 produces the process obtained by replacing the first (in the prefix visit of the syntax tree) hole \bullet with P_1 and the second hole \bullet with P_2 .

Definition 3.2 (Reduction semantics) *The rules in Figure 5, together with symmetric rules of R-COMM and of*

R-SYNC (swapping the processes in the two holes of $\mathcal{D}[], []$), inductively define the reduction relation on processes.

Rule R-SYNC allows a service invocation and a service definition to interact. This interaction produces a pair of complementary sessions, distinguished by a fresh restricted name r . Notice that both the service invocation and the service definition disappear. Rule R-COMM allows communication between corresponding sessions. Then there are the two rules dealing with streams: rule R-FEED puts a value in the stream while rule R-READ takes a value from the stream. Finally rule R-CONG allows reductions to happen inside arbitrary active contexts, and rule R-STR exploits structural congruence.

The reduction semantics is intuitive, but one based on a labeled transition system (LTS, for short) is more convenient for some proofs and allows to exploit bisimulation-based techniques.

Definition 3.3 (LTS semantics) *The rules in Figure 6, together with symmetric versions of rules L-SESS-COM-STREAM and L-SERV-COM-STREAM, inductively define the labeled transition system on processes.*

We highlight some aspects that may be less clear, explaining at the same time the labels used. We use μ as metavariable for labels. Label $\uparrow v$ denotes the output of value v . Dually, $\downarrow v$ is the input of value v . We use $\uparrow v$ to denote either $\uparrow v$ or $\downarrow v$. Also, $a \Rightarrow (r)$ and $a \Leftarrow (r)$ denote respectively the invocation and the reception of an invocation of a service a . Here r is the name of the new session to be created and it is bound. Also, $\uparrow v$ denotes the feeding of v to a stream, while $f \downarrow v$ is the read of value v from stream f . Notice that the value taken in input in rules L-RECEIVE and L-READ is guessed: this is an early semantics. When an input or an output label crosses a session construct (rule L-SESS-VAL), we have to add to the label its name and whether it is a server or client session (for example $\downarrow v$ may become $r \triangleleft \downarrow v$). Notice that we can have two contexts causing interaction: parallel composition and stream. The label denoting a conversation step in a free session r is $r\tau$, and a label τ is obtained only when r is restricted (rule L-SESS-RES). Thus a τ action can be obtained in four cases: a communication inside a restricted session, a service invocation, a feed or a read from a stream. Finally, bound actions $(a)\mu$ are like the respective free counterparts μ , but here a is extruded. There is no need to deal explicitly with these actions since, if the interaction is internal to the system, structural congruence can be used to broaden the scope of a .

We conclude this section with a theorem relating the reduction and the LTS semantics.

Theorem 3.1 (Correspondence theorem) *For each P and Q , $P \rightarrow Q$ if and only if $P \xrightarrow{\tau} Q$.*

$$\begin{aligned}

\end{aligned}$$

Figure 7. Derived constructs

4 Further examples

This section explores examples that highlight the versatility of SSCC. We start by discussing a few macros (see Figure 7) that speed up modeling and suggest how Orc can be mapped in SSCC. The first one invokes an activity (a service which gives back one result) and makes the result available via a feed. The second macro models sequential composition, with parameter passing. The third one more closely models Orc sequential composition, since an instance of Q is executed for each value received from P . The last macro allows to define permanent services.

Example 4.1 (Fork-join) *This example shows that named streams can be handy. Fork-join is a pattern that spawns two threads, and resumes computation after receiving a value from each thread. In the example below, services a and b are run in parallel; **call** a feeds the first result produced by the service into stream f , and similarly for **call** b*

and stream g .

$$\begin{aligned}
\text{fork-and-join } \star \Rightarrow (a)(b)(& \\
\text{stream call } a \text{ as } f \text{ in } & \\
\text{stream call } b \text{ as } g \text{ in } & \\
f(x).g(y).x.y) &
\end{aligned}$$

*The example is inspired by Orc [13, 16] where, but here we do not kill service invocations a and b , instead let them run to completion. Orc is not able to match our semantics: only the **where** construct can read a single value from an expression, and that necessarily means terminating the evaluation of the expression. We feel that termination should be distinct from normal orchestration.*

*It is difficult to model the same pattern in SCC too, since the two clients should use **return** to make their results available, but the two values would be mixed. Auxiliary services are required to match this semantics.*

Example 4.2 (Memory cell) *Even if a memory cell is not a common scenario in SOC, stateful services are. Examples abound in the literature, from data-structures to weblog update [4]. Contrary to SCC [4], our language allows writing stateful services without exploiting service termination. Inspired in the encoding of objects in the pi-calculus [18], we set up a simple, ephemeral, service to produce a value: $\text{buffer} \Rightarrow v$. Service get calls the buffer service to obtain its value (thus consuming the service provider), replies the value to the client, and replaces the buffer service.*

$$\text{get } \star \Rightarrow \text{call } \text{buffer} >^1 v > (v | \text{buffer} \Rightarrow v)$$

$$\begin{array}{c}
v.P \xrightarrow{\uparrow v} P \quad (x)P \xrightarrow{\downarrow v} P[v/x] \quad \text{feed } v.P \xrightarrow{\uparrow v} P \quad f(x).P \xrightarrow{f\downarrow v} P[v/x] \\
\text{(L-SEND, L-RECEIVE, L-FEED, L-READ)} \\
\frac{r \notin \text{fn}(P)}{a \Leftarrow P \xrightarrow{\alpha \Leftarrow (r)} r \triangleleft P} \quad \frac{r \notin \text{fn}(P)}{a \Rightarrow P \xrightarrow{\alpha \Rightarrow (r)} r \triangleright P} \\
\text{(L-CALL, L-DEF)} \\
\frac{P \xrightarrow{\mu} P' \quad \mu \neq \uparrow v \quad \text{bn}(\mu) \cap (\text{fn}(Q) \cup \text{Set}(\vec{w})) = \emptyset}{\text{stream } P \text{ as } f = \vec{w} \text{ in } Q \xrightarrow{\mu} \text{stream } P' \text{ as } f = \vec{w} \text{ in } Q} \quad \frac{Q \xrightarrow{\mu} Q' \quad \mu \neq f \downarrow v \quad \text{bn}(\mu) \cap (\text{fn}(P) \cup \text{Set}(\vec{w})) = \emptyset}{\text{stream } P \text{ as } f = \vec{w} \text{ in } Q \xrightarrow{\mu} \text{stream } P \text{ as } f = \vec{w} \text{ in } Q'} \\
\text{(L-STREAM-PASS-P, L-STREAM-PASS-Q)} \\
\frac{P \xrightarrow{\uparrow v} P'}{\text{stream } P \text{ as } f = \vec{w} \text{ in } Q \xrightarrow{\tau} \text{stream } P' \text{ as } f = v :: \vec{w} \text{ in } Q} \quad \frac{Q \xrightarrow{f\downarrow v} Q'}{\text{stream } P \text{ as } f = \vec{w} :: v \text{ in } Q \xrightarrow{\tau} \text{stream } P \text{ as } f = \vec{w} \text{ in } Q'} \\
\text{(L-STREAM-FEED, L-STREAM-CONS)} \\
\frac{P \xrightarrow{\mu} P' \quad \text{bn}(\mu) \cap \text{fn}(Q) = \emptyset}{P|Q \xrightarrow{\mu} P'|Q} \quad \frac{P \xrightarrow{\downarrow v} P'}{r \bowtie P \xrightarrow{r\bowtie\downarrow v} r \bowtie P'} \quad \frac{P \xrightarrow{\mu} P' \quad \mu \neq \uparrow v \quad r \notin \text{bn}(\mu)}{r \bowtie P \xrightarrow{\mu} r \bowtie P'} \\
\text{(L-PAR, L-SESS-VAL, L-SESS-PASS)} \\
\frac{P \xrightarrow{r\bowtie\uparrow v} P' \quad Q \xrightarrow{r\bowtie\downarrow v} Q'}{\text{stream } P \text{ as } f = \vec{w} \text{ in } Q \xrightarrow{r\tau} \text{stream } P' \text{ as } f = \vec{w} \text{ in } Q'} \quad \frac{P \xrightarrow{\alpha \Rightarrow (r)} P' \quad Q \xrightarrow{\alpha \Leftarrow (r)} Q'}{\text{stream } P \text{ as } f = \vec{w} \text{ in } Q \xrightarrow{\tau} (\nu r)\text{stream } P' \text{ as } f = \vec{w} \text{ in } Q'} \\
\text{(L-SESS-COM-STREAM, L-SERV-COM-STREAM)} \\
\frac{P \xrightarrow{r\bowtie\uparrow v} P' \quad Q \xrightarrow{r\bowtie\downarrow v} Q'}{P|Q \xrightarrow{r\tau} P'|Q'} \quad \frac{P \xrightarrow{\alpha \Rightarrow (r)} P' \quad Q \xrightarrow{\alpha \Leftarrow (r)} Q'}{P|Q \xrightarrow{\tau} (\nu r)(P'|Q')} \quad \frac{P \xrightarrow{\mu} P', P \equiv Q, P' \equiv Q'}{Q \xrightarrow{\mu} Q'} \\
\text{(L-SESS-COM-PAR, L-SERV-COM-PAR, L-STRUCT)} \\
\frac{P \xrightarrow{\mu} P' \quad n \notin \text{n}(\mu)}{(\nu n)P \xrightarrow{\mu} (\nu n)P'} \quad \frac{P \xrightarrow{r\tau} P'}{(\nu r)P \xrightarrow{\tau} (\nu r)P'} \quad \frac{P \xrightarrow{\mu} P' \quad \mu \in \{\uparrow a, r \bowtie \uparrow a, \uparrow a\}}{(\nu a)P \xrightarrow{(a)\mu} P'} \\
\text{(L-RES, L-SESS-RES, L-EXTR)}
\end{array}$$

Figure 6. Labeled transition system

Service set calls the buffer service (in order to consume it), then gets the new value from the client and creates a buffer with this value.

```
set *⇒ call buffer >1> (w)(buffer ⇒ w)
```

Finally, the cell service sets up three services—get, set, and buffer—sends the first two to the client, and keeps buffer locally with initial value 0.

```
cell *⇒ (ν buffer, get, set).get.set.
(buffer ⇒ 0 |
  get *⇒ call buffer >1v >
  (v | buffer ⇒ v) |
  set *⇒ call buffer >1> (w)(buffer ⇒ w))
```

Example 4.3 (Interleaved parallel routing) The workflow patterns of van der Aalst [20] provide a well-known benchmark of orchestration scenarios. Even if these are aimed at workflow languages (and thus, e.g., do not consider conversations or dynamic creation of services), it is interesting to look at them. All the patterns that do not require killing ongoing computations can be implemented. See [14] for a complete description.

In interleaved parallel routing workflow pattern, a set of activities is executed in arbitrary order, and no two activities are executed at the same moment.

We assume that each service (a1 to an) signals termination by sending a value.

Contrary to Orc [8], SSCC is expressive enough to describe the pattern within the language. This requires a backward communication w.r.t. the direction of the stream, and shows that unidirectional streams are expressive enough. A back service relays the values from the right to the left part of a stream construct, where they are fed into the stream.

```
interleave ⇒ (a1) ... (an)(ν back)(
  stream
  back *⇒ (x) feed x
  as lock in
  back ⇒ unit |
  lock(-).a1 ⇒ (x)(back ⇒ unit) | ... |
  lock(-).an ⇒ (x)(back ⇒ unit))
```

Example 4.4 (Complex protocols) One of the main limitations of other proposals, e.g. Orc, is that they allow just very simple kinds of client-server interactions. We show here how sessions can be used to overcome this limitation.

$T ::=$	<i>Types</i>
Unit	unit type
$[U]$	service type
$U ::=$	<i>Conversation types</i>
$?T.U$	input
$!T.U$	output
end	end of conversation
X	type variable
$\text{rec } X.U$	recursive type

Figure 8. The syntax of types

Let us consider an hotel booking: the client sends the dates and the type of room to the hotel, the hotel answers with the price (we skip many details of a real protocol for space constraints), the client provides a credit card, the hotel checks with the bank that the required amount of money is available and sends to the client a confirmation. We show for simplicity just the hotel server, and we suppose to have a server for the bank and a server pricetable to compute the price of the staying.

```

hotel  $\Rightarrow$  (date)(room)
  call pricetable(date,room) >1 price >
  price. (cc) call bank(price,cc) >1 avail >
  if avail then confirm else reject

```

The if-then-else construct can be defined as a macro in the language (see [14]).

5 Protocol compatibility

We present a simple type system to ensure protocol compatibility between clients and servers, inspired by works on session types [10, 12, 19, 22]. Notice that here we can deal with many interacting services at the same time.

Definition 5.1 (Types) *The grammar in Figure 8 defines the syntax of types.*

Types for values, T , are either Unit, which denotes the only basic type¹, and $[U]$ is the type of a service (and of a session) with protocol U . The protocol is always seen from the server point of view. *Types for streams* are of the form $\langle T \rangle$ where T is the type of the values the stream carries. *Types for processes* are of the form (U, T) where U is the protocol followed by the process, and T is the type of the values the process feeds into its stream.

The rec operator for types is a binder, giving rise, in the standard way, to notions of bound and free variables and α -equivalence. Similarly to processes, we do not distinguish

¹To be possibly extended with, say, integers and strings.

$$\begin{array}{l} \overline{?T.U} \triangleq !T.\overline{U} \quad \overline{!T.U} \triangleq ?T.\overline{U} \quad \overline{\text{end}} \triangleq \text{end} \\ \overline{X} \triangleq X \quad \overline{\text{rec } X.U} \triangleq \text{rec } X.\overline{U} \end{array}$$

Figure 9. Complement of a protocol

between α -convertible types. Furthermore, we take an *equi-recursive* view of types [17], not distinguishing between a type $\text{rec } X.U$ and its unfolding $T[\text{rec } X.U/X]$. We are interested on *contractive* (not including subterms of the form $\text{rec } X.\text{rec } X_1 \dots \text{rec } X_n.X$) types only [17].

We need to find whether two protocols are complementary, thus we introduce the complement operation in Figure 9. Intuitively, if a client executes protocol U and a server protocol \overline{U} , the conversation between them can proceed without errors.

Typing judgments are as follows,

$$\begin{array}{ll} \Gamma \vdash P : (U, T) & \text{Processes} \\ \Gamma \vdash v : T & \text{Values} \end{array}$$

where Γ is a map with entries $a : T$, $r : T$, $f : \langle T \rangle$, and $X : (U, T)$. The rules in Figure 10 inductively define the *type system*.

The type of a process abstracts its behavior: the first component shows the protocol of the process while the second component traces the type of the values fed to its stream. Notice that the properties of internal sessions and streams are guaranteed by the typing derivation and the typing assumption in Γ and they do not influence the type of the process. For instance if the process is a session $r \triangleright P$, then its protocol is end, but the protocol followed by P is traced by an assumption $r : [U]$ in Γ . When the complementary session is found, the compatibility check is performed.

Our types force protocols to be sequential: we think that this is a good programming style. Suppose for instance that the protocol contains two parallel outputs: there should be two inputs in the complementary protocol, and one can not know which output is matched with each input. Either this is not important (and one can sort the outputs in an arbitrary way) or it is, and in the last case errors could occur. Also, parallel protocols are more complex to check for protocol compatibility. Notice that this does not forbid, e.g., to have two concurrent service invocations, since sequentiality is only enforced in protocols.

As an example we show the typing judgment for the protocol of the hotel service in Example 4.4.

```

true : Bool, confirm : Flag, reject : Flag  $\vdash$ 
  (date)(room) ... reject :
  ([?Date.?Room.!Int.?CC.!Flag.end], T)

```

We have supposed to have types Bool, Int, Date, Room, CC, and Flag to model domain specific data. Also, the hotel service does not feed into its stream, hence the arbitrary type T .

$\Gamma, n: T \vdash n: T$	$\Gamma, f: \langle T \rangle \vdash f: \langle T \rangle$	$\Gamma \vdash \text{unit}: \text{Unit}$	(T-NAME, T-SNAME, T-UNIT)
$\frac{\Gamma \vdash P: (U, T) \quad \Gamma \vdash v: T'}{\Gamma \vdash v.P: (!T'.U, T)}$	$\frac{\Gamma, x: T' \vdash P: (U, T)}{\Gamma \vdash (x)P: (?T'.U, T)}$		(T-SEND, T-RECEIVE)
$\frac{\Gamma \vdash P: (U, T) \quad \Gamma \vdash a: [U]}{\Gamma \vdash a \Rightarrow P: (\text{end}, T)}$	$\frac{\Gamma \vdash P: (U, T) \quad \Gamma \vdash a: [\bar{U}]}{\Gamma \vdash a \Leftarrow P: (\text{end}, T)}$		(T-DEF, T-CALL)
$\frac{\Gamma \vdash P: (U, T) \quad \Gamma \vdash r: [U]}{\Gamma \vdash r \triangleright P: (\text{end}, T)}$	$\frac{\Gamma \vdash P: (U, T) \quad \Gamma \vdash r: [\bar{U}]}{\Gamma \vdash r \triangleleft P: (\text{end}, T)}$		(T-SESS-S, T-SESS-C)
$\frac{\Gamma \vdash P: (U, T) \quad \Gamma \vdash v: T}{\Gamma \vdash \text{feed } v.P: (U, T)}$	$\frac{\Gamma, x: T \vdash P: (U, T') \quad \Gamma \vdash f: \langle T \rangle}{\Gamma \vdash f(x).P: (U, T')}$		(T-FEED, T-READ)
$\frac{\Gamma \vdash P: (U, T) \quad \Gamma \vdash Q: (\text{end}, T)}{\Gamma \vdash P Q: (U, T)}$	$\frac{\Gamma \vdash P: (\text{end}, T) \quad \Gamma \vdash Q: (U, T)}{\Gamma \vdash P Q: (U, T)}$		(T-PAR-L, T-PAR-R)
$\frac{\Gamma \vdash P: (U, T) \quad \Gamma, f: \langle T \rangle \vdash Q: (\text{end}, T') \quad w \in \text{Set}(\vec{v}) \Rightarrow \Gamma \vdash w: T}{\Gamma \vdash \text{stream } P \text{ as } f = \vec{v} \text{ in } Q: (U, T')}$			(T-STREAM-L)
$\frac{\Gamma \vdash P: (\text{end}, T) \quad \Gamma, f: \langle T \rangle \vdash Q: (U, T') \quad w \in \text{Set}(\vec{v}) \Rightarrow \Gamma \vdash w: T}{\Gamma \vdash \text{stream } P \text{ as } f = \vec{v} \text{ in } Q: (U, T')}$			(T-STREAM-R)
$\frac{\Gamma, X: (U, T) \vdash P: (U, T)}{\Gamma \vdash \text{rec } X.P: (U, T)}$	$\frac{\Gamma, n: _ \vdash P: (U, T)}{\Gamma \vdash (\nu n)P: (U, T)}$		(T-REC, T-RES)
$\Gamma, X: (U, T) \vdash X: (U, T)$	$\Gamma \vdash \mathbf{0}: (\text{end}, T)$		(T-VAR, T-NIL)

Figure 10. The type system

SSCC equipped with this type system is type safe. As usual this result requires a progress property—subject reduction—and a definition of erroneous processes.

Theorem 5.1 (Subject reduction) *Let P be a process such that $\Gamma \vdash P: (U, T)$ and $P \rightarrow P'$. Then $\Gamma \vdash P': (U, T)$.*

Typable processes are not errors, nor can generate errors.

Theorem 5.2 (Type Safety) *Let P be a typable process. Then P has no subterm of the following forms.*

Protocol:

- $\mathcal{D}[r \bowtie \mathcal{C}[v.P], r \bowtie \mathcal{C}'[u.Q]]$ *Two outputs*
 - $\mathcal{D}[r \bowtie \mathcal{C}[v.P], r \bowtie \mathbf{0}]$ *Output and 0*
 - $\mathcal{D}[r \bowtie \mathcal{C}[(x)P], r \bowtie \mathcal{C}'[(y)Q]]$ *Two inputs*
 - $\mathcal{D}[r \bowtie \mathcal{C}[(x)P], r \bowtie \mathbf{0}]$ *Input and 0*
- where in all the cases $\mathcal{D}[_, _]$ does not bind r , and $\mathcal{C}[_]$ and $\mathcal{C}'[_]$ do not contain sessions around the \bullet .

Sequentiality:

- $\mathcal{D}[v.P, u.Q]$ *Parallel outputs*
 - $\mathcal{D}[(x)P, u.Q]$ *Parallel input and output*
 - $\mathcal{D}[v.P, (y)Q]$ *Parallel output and input*
 - $\mathcal{D}[(x)P, (y)Q]$ *Parallel inputs*
- where in all cases $\mathcal{D}[_, _]$ does not contain sessions around the \bullet .

An example of a *protocol failure* is $r \triangleright v.P | r \triangleleft \mathbf{0}$, and this cannot be typed since the two parallel components require different assumptions for r ($r: [!T.U']$ where T is the type of v , and $r: [\text{end}]$ respectively). Similarly a *non-sequential*

conversation is $r \triangleright (v.P | u.Q)$, and this cannot be typed since both $v.P$ and $u.Q$ have non end protocols, thus rules for parallel composition can not be applied.

Techniques used for session types can be adapted to *type check* SSCC processes [21].

6 Further analysis techniques

In this section we propose two “proof of concept” techniques to further highlight the suitability of SSCC.

Service equivalence. Bisimilarity techniques are a common tool used in process calculi to obtain process equivalences. We show here how weak bisimilarity can be used to prove the equivalence between a service and a possible refined implementation.

We write $P \Rightarrow P'$ iff $P \xrightarrow{\tau} \dots \xrightarrow{\tau} P'$ and $P \xrightarrow{\mu} P'$ iff $P \xrightarrow{\mu} P'$.

Definition 6.1 (Bisimilarity) *A weak bisimulation is a relation R such that $P R Q$ implies:*

if $P \xrightarrow{\mu} P' \wedge \text{bn}(\mu) \cap \text{fn}(Q) = \emptyset$ then $Q \xrightarrow{\mu} Q' \wedge P' R Q'$ and vice versa.

Weak bisimilarity is the maximal weak bisimulation.

Let us consider the simple service:

$\text{add2} \Rightarrow (n)n+2$

A possible implementation of this service is:

$$\begin{aligned}
(\nu \text{ add1})(\text{add1} \ast \Rightarrow (n)n+1 \mid \\
\text{add2} \Rightarrow (n) \text{ call } \text{add1}(n) >^1 m > \\
\text{call } \text{add1}(m) >^1 o > o)
\end{aligned}$$

The two services `add2` are weak bisimilar, thus the second one is a correct implementation of the first.

Towards deadlock avoidance. One of the main aims of this calculus is to allow the development of static analysis techniques to ensure liveness properties, like, e.g., deadlock freedom. Even if this is outside the scope of this paper, we highlight the main ideas.

There are three possible causes of deadlock in the language: non matched service definitions/invocations, non matched value sends/receives, and read from empty stream. These correspond respectively to service availability, communication errors, and orchestration errors. The three problems require different techniques: Section 5 shows e.g. how to avoid communication errors. One has also to check that there are no cyclic dependencies (e.g., a service waiting for a value from a stream, which can be produced only after the service execution has been completed). It is not difficult to ensure the following result.

Let P be a process such that:

Service availability: all services are defined, persistent, and at top level, i.e., P has the form $(\nu \vec{a})(D|Q)$ where D is a parallel composition of persistent service definitions for all the services occurring in D and Q ;

Protocol compatibility: P is typable according to the type system in Section 5;

Orchestration: for each subterm `stream` Q' as $f = \vec{v}$ in Q'' we have $n + |\vec{v}| \geq m$ where n is the number of feeds in Q' feeding f (i.e., not in the left part of other stream operators) and m is the number of reads from f in Q'' . We additionally require that no read operation is inside a recursive process.

For each computation $P \xrightarrow{\mu_1} \dots \xrightarrow{\mu_n} P'$, if P' has not the form $(\nu \vec{a}')D$ where D is the same as above (in this case the computation in Q is terminated), there are μ and P'' such that $P' \xrightarrow{\mu} P''$.

The main idea here is to avoid each possibility of blocked processes: all processes at top level can execute an action unless they depend on some other process, but the condition of service availability and directionality in stream communications guarantee that cyclic dependencies are avoided. Note that this result strongly exploits the features of the language, i.e., it would be very difficult to obtain it if unstructured communications are added.

7 Conclusion and future work

SSCC is a typed language aiming at flexibly describing services, conversations, and orchestration, with a restricted

set of constructors. The expressivity of the language is witnessed by the simple implementation of all workflow patterns in [20] (except for the ones that require process termination) available in [14] and by the examples in Sections 2 and 4. We have shown instead in Sections 5 and 6 how different analysis techniques can be applied to the calculus.

Future works will start from there. Some ideas include analyzing the relationships between contextual equivalence and bisimilarity and up-to techniques for bisimilarity, more refined techniques for proving service availability (e.g., linearity of service invocation and definition) and proofs of deadlock freedom for large classes of protocols.

Another thread for future development concerns the development of a *compensation* mechanism to recover from failures, and its behavioral theory.
