**Abstract:** To investigate UV light response mechanisms in higher plants, we isolated a UV light-sensitive mutant, *rev3-1*, in Arabidopsis. The root growth of *rev3-1* was inhibited after UV-B irradiation under both light and dark conditions. We found that chromosome 1 of *rev3-1* was broken at a minimum of three points, causing chromosome inversion and translocation. A gene disrupted by this rearrangement encoded the catalytic subunit of DNA polymerase  $\zeta$  (AtREV3), which is thought to be involved in translesion synthesis. The *rev3-1* seedlings also were sensitive to  $\gamma$ -rays and mitomycin C, which are known to inhibit DNA replication. Incorporation of bromodeoxyuridine after UV-B irradiation was less in *rev3-1* than in the wild type. These results indicate that UV light-damaged DNA interrupted DNA replication in the *rev3-1* mutant, leading to the inhibition of cell division and root elongation.
