**ABSTRACT**

Hydrolysis of ammonia-borane (AB) is one of the most convenient sources of H<sub>2</sub> under ambient conditions, but the reaction requires a good catalyst to become efficient. Here this reaction is catalyzed by bimetallic late transition-metal nanoparticles (NPs) stabilized by “click” dendrimers **1** and **2** containing respectively 27 or 81 terminal triethylene glycol termini and 9 or 27 intradendritic 1,2,3-triazole ligands. A remarkable synergy between Pt and Co in the Pt-Co/“click” dendrimer nanocatalyst is disclosed. These Pt-Co/“click” dendrimer catalysts are much more efficient for hydrolysis of AB than either “click” dendrimer-stabilized Co or Pt analogues alone. The best catalyst Pt<sub>1</sub>Co<sub>1</sub>/**1** stabilized by the nona-triazole “click” dendrimer **1** achieves a TOF of 303 mol<sub>H<sub>2</sub></sub>·mol<sub>catal.</sub><sup>-1</sup>·min<sup>-1</sup> (606 mol<sub>H<sub>2</sub></sub>·mol<sub>Pt</sub><sup>-1</sup>·min<sup>-1</sup>) at 20 ± 1°C. In the presence of NaOH, the reactivity is boosted for hydrolysis of AB catalyzed by Pt<sub>1</sub>Co<sub>1</sub>/**1**, and reaches a TOF value of 476.2 mol<sub>H<sub>2</sub></sub>·mol<sub>catal.</sub><sup>-1</sup>·min<sup>-1</sup> (952.4 mol<sub>H<sub>2</sub></sub>·mol<sub>Pt</sub><sup>-1</sup>·min<sup>-1</sup>), one of the very best results obtained by comparison with the literature. The presence of a percentage of Pt as low as 25% in the CoPt nanoalloy provides a reaction rate higher than with that obtained with the pure Pt NP catalyst alone. The kinetics involves in particular a kinetic isotope effect  $k_D/k_H = 2.46$  obtained for the hydrolysis reaction with D<sub>2</sub>O, suggesting O-H bond cleavage of water in the rate-determining step. Tandem reactions were conducted for the hydrogenation of styrene with hydrogen generated from the hydrolysis of AB. Performing this tandem reaction with D<sub>2</sub>O shows deuteration of the ethylbenzene products confirming O-D cleavage and H/D scrambling on the bimetallic nanoparticle surface. Finally a reaction mechanism is proposed. This dramatic synergy type should also prove useful in a number of other catalytic systems.

**KEYWORDS:** Synergy; nanocatalyst; cobalt; dendrimer; hydrolysis; ammonia borane

## INTRODUCTION

Hydrogen energy is regarded as the most promising clean energy in the 21<sup>st</sup> century. H<sub>2</sub> production upon hydrolysis of ammonia borane (AB) has attracted increasing attention owing to the high AB hydrogen content (19.6 wt%), low molecular weight (30.87 g·mol<sup>-1</sup>) and high stability in solution.<sup>1</sup> Duan and Chen recently reported mechanistic studies for the hydrolysis of AB, showing that the reaction produces NH<sub>4</sub><sup>+</sup>B(OH)<sub>4</sub><sup>-</sup>:<sup>2</sup>

In the past decade, intensive efforts have been devoted to the investigation of potentially efficient and economical catalysts for the hydrolysis of AB.<sup>3,4</sup> Noble-metal nanoparticles (NPs), in particular Pt-based catalysts, have been shown to undergo high hydrogen evolution rates for this reaction.<sup>5</sup> Non-noble-metal NPs catalysts are much less efficient than their noble metal analogues, however.<sup>6</sup> For example, under the same conditions PtNPs and RhNPs showed much higher efficiency than CoNPs and NiNPs for the hydrolysis of AB,<sup>7</sup> but the practical use of precious metals in catalysis is limited owing to their high costs and global scarcities.

Dendrimers have been extensively used as supports and shown to be highly efficient in catalysis,<sup>8</sup> including for the encapsulation or stabilization of transition-metal NP catalysts.<sup>9</sup> Their use to generate hydrogen from hydrogen-rich precursors has been pioneered by Xu's group,<sup>10</sup> but they have very rarely been used for this purpose. Only two reports are known, and they deal with monometallic NPs.<sup>7,10</sup> There is so far no report of dendrimer-stabilized bimetallic nanocatalyst for hydrogen generation. Here we report a series of bimetallic NPs with narrow size distributions stabilized by "click" dendrimers<sup>11</sup> for optimized catalysis of AB hydrolysis using the possible

1  
2  
3 synergy between the two metals.<sup>12</sup> Two water-soluble arene-centered triethylene glycol (TEG)-  
4 terminated “click” dendrimers **1** and **2** of zeroth and first generation containing respectively 27  
5 and 81 TEG tethers are serving as nanoparticle stabilizers (Figure 1). Then homogeneous  
6 bimetallic catalysts are prepared by mixing the two precursor metal salts with one of the  
7 dendrimers in water, followed by reduction of the mixture of the transition-metal salts by NaBH<sub>4</sub>.  
8 These bimetallic nanocatalysts are characterized by transmission electron microscopy (TEM),  
9 high-resolution transmission electron microscopy (HRTEM), high-angle annular dark-field  
10 scanning transmission electron microscopy (HAADF-STEM), energy dispersive X-ray  
11 spectroscopy (EDS) and X-ray photoelectron spectra (XPS). Among these click-dendrimer  
12 templated bimetallic NPs, the nanoalloy Pt<sub>1</sub>Co<sub>1</sub>/1 is shown to be the most active and efficient  
13 nanocatalyst for AB hydrolysis, achieving a TOF value of 952.4 mol<sub>H<sub>2</sub></sub>·mol<sub>Pt</sub><sup>-1</sup>·min<sup>-1</sup>. The  
14 influence of NaOH<sup>13</sup> on the reaction efficiency for various bimetallic NPs is investigated. Kinetic  
15 isotope effects (KIEs)<sup>14</sup> using D<sub>2</sub>O instead of H<sub>2</sub>O and tandem reaction for hydrogenation of  
16 styrene are also examined for the mechanistic study of this reaction.

## RESULTS AND DISCUSSION

### Synthesis and Characterizations of the Pt-Co/1 NPs.

The synthesis of the “click” dendrimers **1** and **2** was conducted following previous reports.<sup>11</sup> The Pt-Co/1 NPs were prepared by mixing dendrimer **1** with two precursor metal salts in water followed by stirring 30 min under N<sub>2</sub>. Then a freshly prepared aqueous solution of NaBH<sub>4</sub> was added, and stirring was continued for 1h (Scheme 1 and SI).

**Scheme 1.** Synthesis of the Pt-Co/1 NPs.

TEM images were recorded for the Pt-Co/1 NPs series, and the average particle sizes were between 1.5 nm and 2.0 nm (Figure S3-5). Very fine and Pt<sub>1</sub>Co<sub>1</sub>/1 NPs with narrow size distribution were indicated by TEM with an average size around 2 nm (Figure 2).

**Figure 2.** (a) TEM image (insert is the HRTEM image) and (b) size distribution of Pt<sub>1</sub>Co<sub>1</sub>/1.

A good crystallinity of Pt<sub>1</sub>Co<sub>1</sub>/1 NPs was confirmed as shown by the clear lattice fringes in HRTEM (Figure 2a insert). The lattice spacing is about 2.2 Å, assuming that the crystallographic plane of the Pt<sub>1</sub>Co<sub>1</sub> nanoalloy is {111} (JCPDS 43-1358). The analysis by Energy Dispersive X-Ray Spectroscopy (EDS) of the Pt<sub>1</sub>Co<sub>1</sub>/1 NPs showed that the Pt and Co elements were present in the 011 area (Figure S6), and the alloy structure of Pt<sub>1</sub>Co<sub>1</sub>/1 NPs was verified by the HAADF-elemental mapping spectra (Figure S7). The EDS measurements clearly showed that the alloys did not contain any monometallic NPs.

X-ray photoelectron spectroscopy (XPS) analysis of the Pt<sub>1</sub>Co<sub>1</sub>/1 NPs showed binding energies of 71.1 and 74.4 eV for the 4f<sub>7/2</sub> and 4f<sub>5/2</sub>, respectively, indicating the presence of metallic Pt(0) (Figure 3a). In addition a binding energy of 778.6 eV was observed for Co 2p<sub>3/2</sub>, showing the existence of Co(0). Another peak around 782.0 eV demonstrated that there is some Co(II) species in the Pt<sub>1</sub>Co<sub>1</sub>/1 NP sample, probably due to partial oxidation of Co(0) just before or during the XPS experiment (Figure 3b). Indeed, catalysis experiments were conducted just after the syntheses and were not subjected of such sample handling. Therefore it is believed that the Co(II)

species was not present during catalysis. Since the intradendritic triazole ligands are neutral, surface atoms are indeed expected to be Co(0) and Pt(0).

**Figure 3.** XPS spectrum of (a) Pt 4f and (b) Co 2p in Pt<sub>1</sub>Co<sub>1</sub>/1 nanocatalyst. The presence of some Co(II) most probably results from partial oxidation of the sample just before or during the XPS experiment.

### Synergistic catalysis of ammonia borane hydrolysis by various Pt-Co NPs/1.

AB hydrolysis catalyzed by various Pt-Co/1 NPs (1 mol%) stabilized by dendrimer **1** was conducted at  $20 \pm 1^\circ\text{C}$  (Table 1, see the kinetics in Figure 4). The compositions of the Pt-Co/1 NPs were adjusted by varying the molar ratios of the precursors. The naming Pt-Co/1 NPs will be used in the following text for alloys of NPs containing both PtNPs and CoNPs in any proportions in dendrimer **1**. The proportions of each metal in the alloy will be indicated by the numbers following the Pt and Co symbols (for instance Pt<sub>1</sub>Co<sub>1</sub> for equal amounts of Pt and Co in the alloy, etc.).

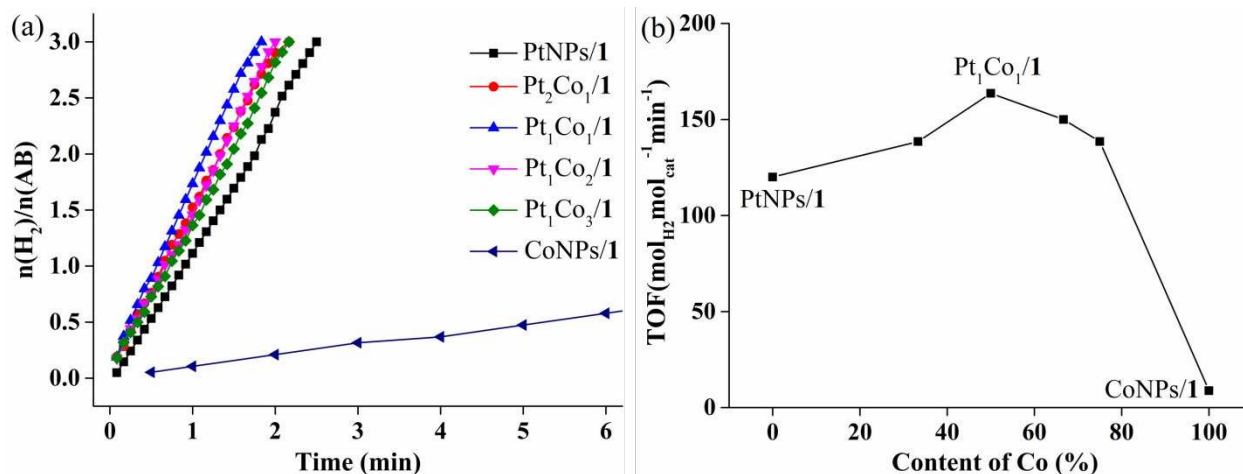

It is known that Pt is a very efficient metal for the hydrolysis of AB. For example, the PtNPs/1 led to a TOF value of  $120 \text{ mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$ . The performance of CoNPs/1, however, was not

1  
2  
3 very good for this reaction, its TOF value being only  $8.8 \text{ mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$ .<sup>7,15</sup> Interestingly,  
4  
5 when Co was introduced to form a Pt-Co alloy NP, the catalyst Pt<sub>1</sub>Co<sub>1</sub>/1 led to a TOF value of  
6  
7 163.6  $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$  for the hydrolysis of AB. Pt<sub>1</sub>Co<sub>1</sub>/1 was the best catalyst among the  
8  
9 whole Pt-Co NP series, and the TOF value decreased from its maximum value when the Co  
10  
11 proportion in the Pt-Co alloy was higher than 1/2. For instance the TOF value of Pt<sub>1</sub>Co<sub>2</sub>/1 was 150  
12  
13  $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$  for this reaction. All the alloyed Pt-Co NPs gave better results than the  
14  
15 catalyst PtNPs/1 or CoNPs/1. In particular it is remarkable that the introduction of only 25% of Pt  
16  
17 to Pt-Co alloy led to a better nanocatalyst than PtNPs/1 alone (Figure 4). In addition, with a  
18  
19 mixture of PtNPs/1 and CoNPs/1 (ratio of Pt:Co of 1:1) and a total catalyst amount fixed at 1%,  
20  
21 AB hydrolysis was conducted, and 6 min was needed for complete H<sub>2</sub> generation, which is  
22  
23 slower than 1% Pt<sub>1</sub>Co<sub>1</sub>/1 NPs or even than 1% PtNPs/1 NPs (Figure S14), demonstrating that  
24  
25 there is no synergy with the physical mixture of these CoNPs/1 and PdNPs/1.  
26

33 **Table 1.** Core sizes and catalytic efficiencies of various Pt-Co/1 NPs catalysts in the presence and  
34 absence of 0.3 M NaOH at  $20 \pm 1^\circ\text{C}$ .

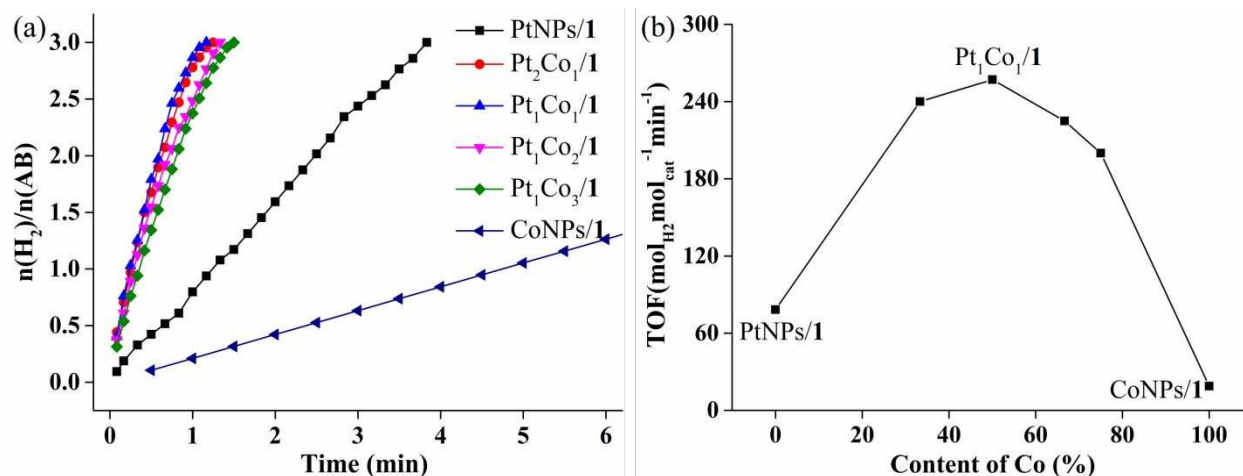

Catalyst <sup>[a]</sup>	Average Size (nm)	TOF <sup>[b]</sup> ( $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{cat}}^{-1} \cdot \text{min}^{-1}$ )	TOF in the presence of 0.3M NaOH
PtNPs/1 <sup>[c]</sup>	2.3	120	78.3
Pt <sub>2</sub> Co <sub>1</sub> /1	1.5	138.5	240
Pt <sub>1</sub> Co <sub>1</sub> /1	2.0	163.6	257.1
Pt <sub>1</sub> Co <sub>2</sub> /1	1.7	150	225
Pt <sub>1</sub> Co <sub>3</sub> /1	1.5	138.5	200
CoNPs/1 <sup>[c]</sup>	2.2	8.8	18.8

[a] 1.0 mol % Pt-Co/1 NPs were used in the catalyzed AB hydrolysis at  $20 \pm 1^\circ\text{C}$ ;  $\text{NaBH}_4$  excess (10/1); [b]  $\text{TOF} = \text{mol}_{\text{H}_2} \text{ released} / (\text{mol}_{\text{catalyst}} \times \text{reaction time}_{(\text{min})})$  related to the all atoms (see also Table S1 for TOF related to surface atoms); [c] experiment results from a previous study.<sup>7</sup>

**Figure 4.** (a) Hydrogen evolution and (b) TOF comparison of  $\text{NH}_3\text{BH}_3$  by 1 mol% various Pt-Co/1 nanocatalyst.

The catalytic performances of the monometallic nanocatalysts PtNPs/1 and CoNPs/1 toward the hydrolysis of AB in the presence of NaOH were tested earlier.<sup>7</sup> It was found that NaOH had a positive influence on the AB hydrolysis catalyzed by CoNPs/1, but a negative influence on PtNPs/1. So the hydrolysis of AB catalyzed by Pt-Co/1 NPs series in the presence of NaOH were conducted (Figure 5), and the influence of various amounts of NaOH (0.1 M~0.4 M) was further investigated. The results show that the reaction rates were boosted, higher TOF values being obtained for Pt-Co/1 NPs in the presence of NaOH. The best TOF value of 257.1  $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$  was reached by Pt<sub>1</sub>Co<sub>1</sub>/1 in the presence of 0.3 M NaOH (Table S2 and Figure S15), and the TOF value decreased with higher NaOH concentration such as 0.4 M.

**Figure 5.** (a) Hydrogen evolution and (b) TOF comparison of  $\text{NH}_3\text{BH}_3$  by 1 mol% various Pt-Co/1 nanocatalyst in the presence of 0.3 M NaOH.

The TOF value of PtNPs/1 decreased from 120 to  $78.3 \text{ mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$  after adding 0.3 M NaOH, but the presence of NaOH had a positive influence on the Pt-Co/1 NPs series. Remarkably all the Pt-Co/1 NPs in the various Co/Pt proportions tested present very high synergistic effects between these two metals in the presence of 0.3 M NaOH. The synergy culminates for equal amounts of Co and Pt in the alloy, as in the absence of NaOH, but it is much higher in the presence of NaOH than in its absence in all the proportions of Co/Pt (Figure 6).

**Figure 6.** TOF comparison of  $\text{NH}_3\text{BH}_3$  by 1 mol% various Pt-Co/1 nanocatalyst in the absence and in the presence of 0.3 M NaOH.

### High selectivity of $\text{Pt}_1\text{Co}_1/1$ compared to other bi-metallic/1 NPs.

A series of late-transition bimetallic NPs,  $\text{Rh}_1\text{Co}_1/1$ ,  $\text{Ru}_1\text{Co}_1/1$ ,  $\text{Pt}_1\text{Ni}_1/1$  and  $\text{Pt}_1\text{Cu}_1/1$  were synthesized using the same method as that used for the syntheses of the nanocatalysts  $\text{Pt}_1\text{Co}_1/1$ . TEM images were recorded for these bimetallic NPs (Figure S8-11). The reactions of AB hydrolysis catalyzed by these bimetallic NPs/1 (1 mol%) in the absence and presence of 0.3 M NaOH were conducted at  $20 \pm 1^\circ\text{C}$  (Table 2, see kinetics in Figure 7).

Furthermore, the NPs  $\text{Pt}_1\text{Co}_1$  stabilized by the first generation dendrimer **2** was synthesized (Figure S12), and the catalytic performances of the  $\text{Pt}_1\text{Co}_1$  NPs stabilized by two dendrimers were compared for AB hydrolysis. The  $\text{Pt}_1\text{Co}_1$  NPs stabilized by the zeroth-generation dendrimer **1** showed slightly better results than those obtained using the first-generation dendrimer **2**. The latter led to a TOF value of  $100 \text{ mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$ . The dendrimer generation effect<sup>8b</sup> was

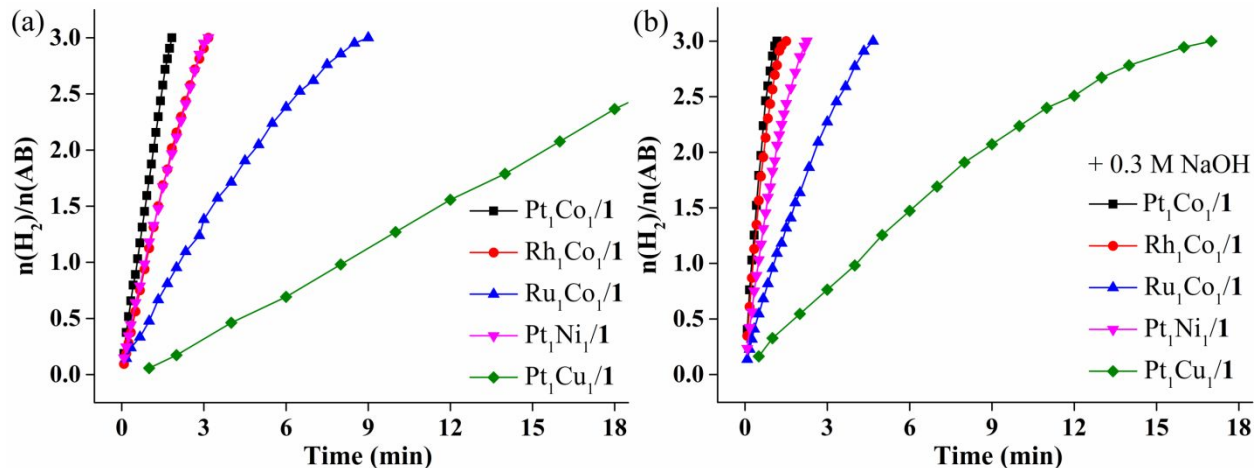

found to be weak, probably due to the interdendritic NP stabilization and/or the NP stabilization near the dendrimer periphery.

**Table 2.** Core sizes and catalytic efficiencies of the bimetallic NPs/**1** catalysts in the presence and absence of 0.3 M NaOH at  $20 \pm 1^\circ\text{C}$ .

Catalyst <sup>[a]</sup>	Average size (nm)	TOF <sup>[b]</sup> ( $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{cat}}^{-1} \cdot \text{min}^{-1}$ )	TOF in the presence of 0.3M NaOH
Pt <sub>1</sub> Co <sub>1</sub> / <b>1</b>	2.0	163.6	257.1
Rh <sub>1</sub> Co <sub>1</sub> / <b>1</b>	1.8	94.7	200
Ru <sub>1</sub> Co <sub>1</sub> / <b>1</b>	2.1	33.3	64.3
Pt <sub>1</sub> Ni <sub>1</sub> / <b>1</b>	1.8	94.7	133.3
Pt <sub>1</sub> Cu <sub>1</sub> / <b>1</b>	1.8	12	17.6
Pt <sub>1</sub> Co <sub>1</sub> / <b>2</b>	2.0	100	163.6

[a] 1.0 mol % bimetallic NPs were used in the catalyzed AB hydrolysis at  $20 \pm 1^\circ\text{C}$ ; NaBH<sub>4</sub> excess (10/1); [b] TOF =  $\text{mol}_{\text{H}_2}$  released / ( $\text{mol}_{\text{catalyst}} \times \text{reaction time}_{(\text{min})}$ ) related to all atoms (see also Table S3 for TOF related to surface atoms).

The comparison showed that Pt<sub>1</sub>Co<sub>1</sub>/**1** exhibited the best efficiency among these bimetallic NP catalysts, followed by the nanocatalysts Rh<sub>1</sub>Co<sub>1</sub>/**1** and Pt<sub>1</sub>Ni<sub>1</sub>/**1**. The same TOF value of 94.7  $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$  was achieved by the latter two catalysts. The TOF value of PtNPs/**1** was 120  $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$ , which indicated that there was no synergy between Pt and Ni. A similar conclusion was reached for Rh and Co, because the TOF value of RhNPs/**1** was 120  $\text{mol}_{\text{H}_2} \cdot \text{mol}_{\text{catal}}^{-1} \cdot \text{min}^{-1}$ .<sup>7</sup> All the AB hydrolysis reactions catalyzed by these bimetallic NPs were accelerated in the presence of 0.3 M NaOH, as shown by comparison with the results obtained in the absence of NaOH (Figure S16-17).

**Figure 7.** Comparison of the hydrogen evolution upon reaction between  $\text{NH}_3\text{BH}_3$  and  $\text{H}_2\text{O}$  catalyzed by 1 mol% bimetallic NPs/1 (a) in the absence of NaOH and (b) in the presence of 0.3 M NaOH.

The durability of the best catalyst  $\text{Pt}_1\text{Co}_1/1$  has been checked because of its importance for practical applications (Figure 8). Another equivalent of AB (1 mmol) was injected into the flask after the end of a reaction, and the second round was started. The AB hydrolysis reactions were repeated several times in this way. The results showed that after five cycles the  $\text{Pt}_1\text{Co}_1/1$  nanocatalyst still presented a good catalytic property for AB hydrolysis. After the 5<sup>th</sup> catalyst recycling the size of the catalyst has now been re-measured by TEM indicating size increase (Figure S13). It is believed that NP size increase and agglomeration and concomitant activity decrease in the 5<sup>th</sup> recycling shown in Figure 8 are due to the accumulation of the sodium and ammonium products of the reaction adsorbing on the NP surface.

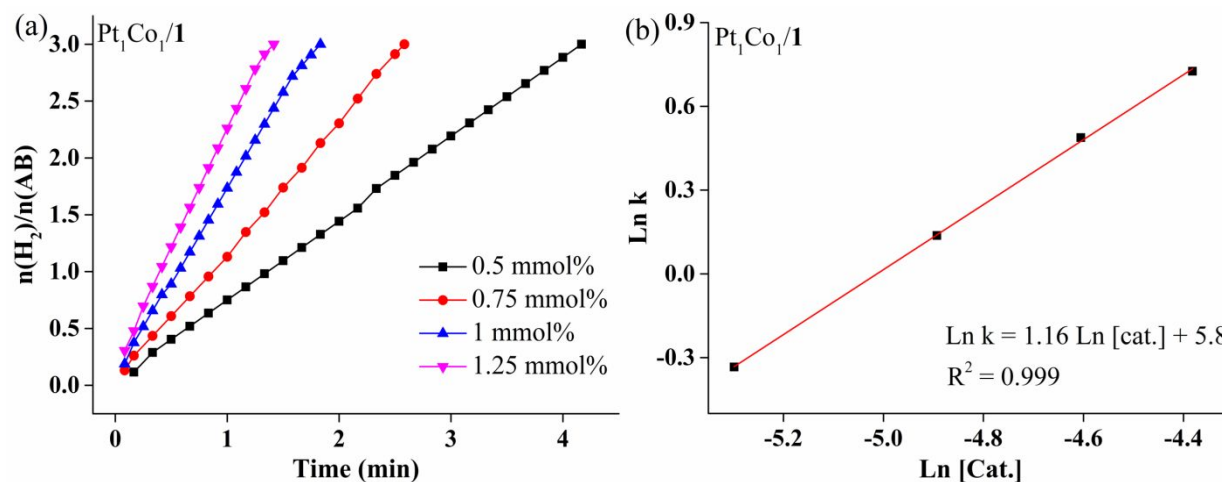

**Figure 8.** Plots of volume of H<sub>2</sub> vs. time for the hydrolysis of AB catalyzed by 1 mol% Pt<sub>1</sub>Co<sub>1</sub>/1 during the reusability tests.

### Mechanistic studies for the AB hydrolysis reaction catalyzed by Pt<sub>1</sub>Co<sub>1</sub>/1

The determination of the second Damköhler number ( $Da_{II} = 0.02$ ), much lower than unity, allowed ruling out mass-transfer-induced diffusion control (see S.I.). The slope of the logarithmic plot of H<sub>2</sub> generation vs. concentration of Pt<sub>1</sub>Co<sub>1</sub>/1 is 1.16 (Figure 9), showing that the reaction is first order in catalyst concentration.

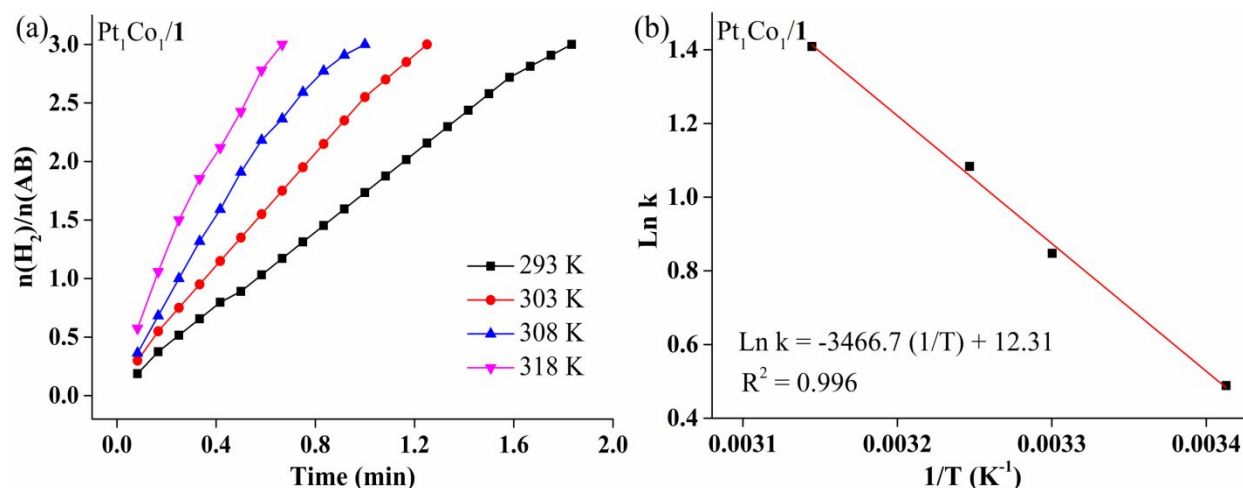

**Figure 9.** Time plots of the catalytic dehydrogenation of AB by Pt<sub>1</sub>Co<sub>1</sub>/1 nanocatalyst with various catalysts (a), and plot of hydrogen generation rate vs. concentration of the nanocatalyst Pt<sub>1</sub>Co<sub>1</sub>/1 both in natural logarithmic scale (b).

The reaction is zero order in AB concentration (the slope of the logarithmic plot of H<sub>2</sub> generation vs. concentration of AB is a nearly horizontal line; slope: 0.09 in Figure 10), which rules out activation of AB alone in the rate-determining step.

**Figure 10.** Plots of volume of H<sub>2</sub> generated vs. time for AB hydrolysis catalyzed by 1 mol% of Pt<sub>1</sub>Co<sub>1</sub>/1 nanocatalyst (a), and plot of the hydrogen generation rate vs. the concentration of AB both in natural logarithmic scale (b).

The measure of the time dependence of H<sub>2</sub> generation at various temperatures led to the determination of a low activation energy ( $E_a$ ) of 28.8 kJ·mol<sup>-1</sup> for Pt<sub>1</sub>Co<sub>1</sub>/1 (Figure 11 and see calculation in the SI).

**Figure 11.** Plots of the volume of H<sub>2</sub> vs. time for the hydrolysis of AB at various temperatures catalyzed by 1 mol% of Pt<sub>1</sub>Co<sub>1</sub>/1 catalyst (a), and Arrhenius plots obtained from the kinetic data (b).

The isotopic experiment using D<sub>2</sub>O instead of H<sub>2</sub>O was conducted for the Pt<sub>1</sub>Co<sub>1</sub>/1-catalyzed AB hydrolysis, and the kinetic results are presented in Figure 12, showing a large kinetic isotope effect (KIE) of 2.46. The kinetic studies, and in particular the latter experiment, suggests cleavage of a water O-H bond in the rate-determining step.

**Figure 12.** Hydrogen evolution from  $\text{NH}_3\text{BH}_3$  with  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$  catalyzed by 1 mol% of the nanocatalyst  $\text{Pt}_1\text{Co}_1/1$  (KIE = 2.46).

In conclusion the results obtained here show a strong and remarkable bimetallic synergy between cobalt and platinum optimized in the  $\text{Co}_1\text{Pt}_1$  alloy, in particular in the presence of 0.3 M NaOH. This synergy also involves the “click” dendrimer supports, in particular the intradendritic 1,2,3-triazole ligands that have proven to be essential.<sup>9g, 11c, 16</sup> Previously the coordination of various transition-metal NPs to the triazole ligands of the same dendrimer **1** near the dendrimer periphery has been shown to be highly beneficial for NP catalysis. This has been demonstrated in very efficient catalysis by PdNP/**1** with ppm Pd amounts for various carbon-carbon cross coupling reactions (Miyaura-Suzuki, Sonogashira, and Heck),<sup>11c, 16b-d</sup> by CuNP/**1** for “click” reactions,<sup>9g, 16e</sup> and by a variety of transition metal NPs/**1** for nitrophenol reduction.<sup>16f-g</sup> Altogether these “click” dendrimer **1** and **2**, i.e. containing the intradendritic 1,2,3-triazole ligands, have been shown to boost catalysis of a various reactions by molecular, ionic and NP catalysts. The electronic donicity of the triazole ligand onto the NP surfaces is responsible for the superior catalytic activity of these

1  
2  
3 NP surfaces,<sup>16e</sup> in particular here for the difficult oxidative addition of the water O-H bond in the  
4 rate-determining step. Note that the fully stable “click” dendrimers **1** and **2** are also used in  
5 catalytic amounts and recovered unchanged in the aqueous phase at the end of the reactions. The  
6 present results are among the very best obtained compared to results on related bimetallic  
7 nanocatalysts in the literature as shown in the comparison Table S4.

18 The practical usages of hydrogen produced in the AB hydrolysis reaction are not only for  
19 hydrogen storage, but also for its direct use *in situ*, for tandem reactions, and for mechanistic  
20 studies of the AB hydrolysis reaction. Examples of the latter applications are shown here. Tandem  
21 reactions were conducted for the hydrogenation of styrene with hydrogen generated from AB  
22 hydrolysis with D<sub>2</sub>O. In a sealed two-chamber system (Figure S18), the hydrogen was produced  
23 from AB with D<sub>2</sub>O, the reaction being catalyzed by Pt<sub>1</sub>Co<sub>1</sub>/1 in the left tube. This hydrogen is  
24 used for the hydrogenation<sup>17</sup> of styrene catalyzed by Ni<sub>2</sub>Pt@ZIF-8<sup>18</sup> in the right tube (Figure 13,  
25 see details in the Supporting Information). The reaction mixture of styrene hydrogenation was  
26 stirred at 50 °C for 12 h, then the <sup>1</sup>H NMR and GC mass spectra of the hydrogenation product  
27 were checked. The integration of the <sup>1</sup>H NMR peak around 1.2 and 2.6 ppm showed a reduced  
28 intensity compared to that of ethylbenzene in its <sup>1</sup>H NMR spectrum (Figure S19). Three peaks  
29 around 106, 107 and 108 were found in the mass spectrum (Figure S20), showing that there were  
30 three hydrogenation products of styrene, which contained respectively 0, 1 and 2 D atoms in the  
31 ethyl substituent, respectively.

**Figure 13.** Tandem reaction for hydrogenation with “HD” generated from AB catalyzed by Pt<sub>1</sub>Co<sub>1</sub>/1. On the arrow, “HD” represents a mixture of H<sub>2</sub>, HD and D<sub>2</sub> (see text).

Several mechanisms have been proposed for the late transition-metal NP-catalyzed hydrolysis of AB. Xu et al proposed attack of H<sub>2</sub>O onto an activated complex provoking B-N cleavage, followed by hydrolysis of NH<sub>3</sub> generating H<sub>2</sub>.<sup>3</sup> Jagirdar’s group proposed attack of H<sub>2</sub>O on a transient M-H bond by analogy with the hydrolysis of BH<sub>4</sub><sup>-</sup>.<sup>19</sup> Na and Ma also proposed a similar mechanism related to BH<sub>4</sub><sup>-</sup> hydrolysis.<sup>20</sup> Fu suggested the formation of BH<sub>3</sub>OH·NH<sub>4</sub><sup>+</sup> followed by H<sub>2</sub>O attack to generate H<sub>2</sub>.<sup>21</sup> Chen<sup>2</sup> and Fu<sup>18</sup> proposed cleavage of the O-H bond of water in the rate-determining step.

1  
2  
3 A mechanistic proposal based on our experiment results follows. An essential mechanistic feature  
4 appears to be the hydrogen bonding between AB and water, i.e.  $[\text{H}_3\text{NBH}_2\text{H}]\dots\text{H}-\text{OH}$ . Such H-  
5  
6 bonding results from the hydridic property of the B-H bond. A hydridic BH is proposed to transfer  
7  
8 its H atom to the NP surface, which formally corresponds to an oxidative addition of this B-H  
9  
10 bond onto the surface. Oxidative addition of the water O-H bond occurs in the rate-determining  
11  
12 step, as essentially indicated from the large KIE ( $k_{\text{H}}/k_{\text{D}} = 2.46$ ) with  $\text{D}_2\text{O}$ . The favorable OH-  
13  
14 effect for bimetallic NPs/**1** is consistent with coordination of OH- onto the NP surface, which  
15  
16 makes the NP more electron-rich and beneficial to the oxidative addition of  $\text{H}_2\text{O}$ . On the contrary,  
17  
18 OH- has a negative effect on AB hydrolysis catalyzed by PtNPs/**1**. The reason probably is that the  
19  
20 hydrogen bonding between AB and  $\text{H}_2\text{O}$  is sufficient to favor O-H oxidative addition by the most  
21  
22 electron-rich PtNPs surface. Accordingly there is no need at this point to further enrich the  
23  
24 electron density of the monometallic PtNP surface by OH- coordination. Furthermore, the added  
25  
26 OH- would partly occupy the surface active sites of PtNPs, inhibiting the oxidative addition of the  
27  
28 water O-H bond, thereby decelerating the reaction. In this step, synergy between a Pt atom and a  
29  
30 Co is likely to operate. The more electron-rich Pt NP atom would most probably form both Pt-H  
31  
32 bonds due to the high strength of the Pt-H bonds, while the less electron-rich Co atom would bind  
33  
34 the electron-rich OH group to form a Co-OH bond. The di-hydride-nanoparticle species would  
35  
36 then easily form  $\text{H}_2$  by reductive elimination as is well known in transition-metal organometallic  
37  
38 chemistry and catalysis.<sup>22</sup> The tandem reaction with  $\text{D}_2\text{O}$  showing deuteration of the ethylbenzene  
39  
40 products confirms H/D exchange subsequently to O-D cleavage and H/D scrambling on the  
41  
42 nanoparticle surface before reductive elimination. Given the KIE value and the favorable effect of  
43  
44 OH- on the reaction rate, it is not possible that protonation of AB by water (heterolytic  $\text{H}_2\text{O}$  or  
45  
46  $\text{D}_2\text{O}$  cleavage) occurs before the rate-limiting step. A tentative reaction mechanism is represented  
47  
48  
49  
50  
51  
52  
53

in Scheme 2. Reductive elimination of  $\text{H}_2$  is accompanied by reductive elimination of the two fragments  $\text{NH}_3\text{BH}_2^-$  and  $\text{OH}^-$  to form the hydroxy intermediate  $\text{NH}_3\text{BH}_2\text{OH}$ . This first overall step (a) thus corresponds to the substitution in ammonia borane of an H atom by OH on boron. Each of the two subsequent  $\text{H}_2$  evolution steps (b) and (c) are proposed to proceed by the same mechanism leading to adsorbed  $\text{B}(\text{OH})_3\text{NH}_3$  that upon hydrolysis produces  $\text{NH}_4^+\text{B}(\text{OH})_4^-$  (d).

**Scheme 2.** Proposed mechanism for the hydrolysis of AB catalyzed by  $\text{Pt}_1\text{Co}_1/1$ .

## CONCLUDING REMARKS

In conclusion, two generations of “click” dendrimers stabilized various bimetallic NPs that catalyze AB hydrolysis producing 3 mol hydrogen. The reaction is zero order in AB and first order in NP catalyst. A remarkably highly positive synergistic effect is discovered for the nanocatalysts Pt-Co/1 containing various proportions of Co and Pt NPs in the nanoalloys, so that the presence of even down to 25% Pt in the nanocatalyst Pt-Co/1 produces a catalyst that is more efficient than PtNP/1. NaOH increases the reaction rate, except for PtNPs. The maximum synergistic effect is disclosed both in the absence and presence of 0.3 M NaOH with nanoalloys containing equal amounts of Co and Pt. This dramatic synergy between Pt and Co is highly selective compared to other bimetallic NPs stabilized by the dendrimer 1. With other supports these PtCo nanoalloys are on the contrary less efficient. Thus the synergy also involves the dendrimer, in particular its intradendritic 1,2,3-triazole ligands that activate the NP surface. The TOF value reached with Pt<sub>1</sub>Co<sub>1</sub>/1 is 476.2 mol<sub>H<sub>2</sub></sub>·mol<sub>catal.</sub><sup>-1</sup>·min<sup>-1</sup> (952.4 mol<sub>H<sub>2</sub></sub>·mol<sub>Pt</sub><sup>-1</sup>·min<sup>-1</sup>) for the production of 3 mol H<sub>2</sub> completed in 70 s at 20°C (Table S1), one of the best results ever recorded. The large kinetic isotope effect ( $k_H/k_D = 2.46$ ) with D<sub>2</sub>O indicates that the cleavage of the O-H bond of water occurs in the rate-determining step. This mechanism is suggested to involve oxidative addition of a hydridic B-H bond of AB to the NP facilitated by hydrogen bonding between a B-H bond of AB and a H atom of water. This is followed by reductive elimination of H<sub>2</sub> and NH<sub>3</sub>BH<sub>2</sub>OH and two analogous overall steps before hydrolysis to NH<sub>4</sub><sup>+</sup>B(OH)<sub>4</sub><sup>-</sup>. The tandem reaction with D<sub>2</sub>O that involves AB hydrolysis-styrene hydrogenation producing deuterated ethylbenzenes confirms O-D cleavage in the rate-limiting step followed by H/D scrambling on the nanoparticle surface before reductive elimination of HD, H<sub>2</sub>, and D<sub>2</sub>.
