#### Abstract

A highly modular approach to $N$-substituted 4-(1-fluorovinyl)triazoles is described. In situ desilylation and Cu -catalyzed ligation reaction of TMS-protected $\alpha$-fluoropropargyl benzothiazole sulfone with aryl, alkyl, and metallocenyl azides furnished second-generation Julia-Kocienski reagents in good to excellent yields. Condensation reactions of these reagents with aldehydes can be tuned to yield $E$ or $Z$-alkenes selectively. Under mild conditions with DBU as base, reactions of aldehydes furnished $E$-alkenes as the major isomer. On the other hand, in condensations with LHMDS as base and in appropriate solvents, both aldehydes and ketones reacted to yield fluoroalkenes with $Z$-selectivity. Stereochemical assignment to $E Z Z$ olefins obtained in the reaction of a ketone with two Julia reagents was performed via X-ray crystallographic analysis and comparisons of NMR data. The method allows efficient and ready diversification of $N \mathrm{l}-$ substituent and substituents at the double bond.

## Introduction

The high modularity and $100 \%$ atom economy of the Huisgen ligation make this an attractive approach to the triazole moiety. ${ }^{1}$ As a class both 1,4 - and 1,5 -disubstituted 1,2,3-

[^0]triazoles are highly valuable in a number of areas, from materials and polymer chemistry, to pharmaceutics and medicine. ${ }^{2}$ The complexation of the triazole ring has also been exploited in supramolecular chemistry. ${ }^{3}$ Discovery of the Cu-catalyzed variant of the Huisgen ligation enabled facile and highly regioselective access to 4 -substituted 1,2,3-triazoles. ${ }^{4,5}$ This prompted resurgence of the azide-alkyne cycloaddition, leading to plethora of 1,2,3-triazolederived structures. Figure 1 shows some representative examples of 1,4-disubstituted 1,2,3-triazole-containing biologically active compounds, ${ }^{6,7}$ as well as new macromolecules with valuable mechanical and/or thermal properties. ${ }^{2 d-f, 8}$

In the area of fluoroorganic chemistry, ${ }^{9}$ we ${ }^{10,11}$ and others ${ }^{12}$ have been involved in modular synthesis of variously functionalized fluoroolefins ${ }^{10,13}$ using Julia-Kocienski approach. ${ }^{14}$ The effect of fluorine atom incorporation on pharmaceuticals is well established. ${ }^{15}$ For example, $Z$ - and $E$-fluorovinyl groups are hydrolytically stable isosteres of trans and of cis peptide bonds, respectively. ${ }^{16}$ Given the high modularity of the azide-alkyne cycloadditions (CuAAC) as well as the Julia-Kocienski olefination, we became interested in a facile approach to merging of the pharmacologically interesting triazole and fluorovinyl moieties. We recently described an approach to 4-vinyl and 4-(a-fluorovinyl)-triazoles via the use of a building block containing a triple bond and an olefination handle. Although synthesis of $N$ fluorovinyl triazoles ${ }^{17}$ has been reported, our preliminary communication ${ }^{11 \mathrm{a}}$ was, to the best of our knowledge, the first report on the synthesis of 4-(a-fluorovinyl)-triazoles.

In our preliminary communication ${ }^{11 \mathrm{a}}$ we demonstrated that regioselectively difunctionalized triazoles, with readily varied $N 1$ and vinyl substituents could be accessed by a combination of the CuAAC and the Julia-Kocienski reactions. In that work we showed that triazolesubstituted Julia-Kocienski reagents can be first obtained via a Cu-catalyzed azide-alkyne click ligation of propargyl and a-fluoropropargyl benzothiazole sulfones with one aryl and two alkyl azides. The resulting reagents then underwent olefination reactions with aldehydes and a ketone. Herein, we describe the broader generality of the azide-alkyne ligation reactions of a-fluoropropargyl benzothiazole sulfone with a larger series of azides, and the reactivity of these second-generation Julia-Kocienski reagents in olefinations with aldehydes and ketones. Notably, evaluation of olefination conditions showed that selectivity could be tuned to yield $E$ - or $Z$-fluorovinyl triazoles as the major isomer in the Julia-Kocienski reactions. This adds to the overall modularity of this approach.

## Results and Discussion

In order to explore the generality of azide-alkyne ligation reactions leading to secondgeneration Julia-Kocienski reagents, TMS-protected $\alpha$-fluoropropargyl benzothiazole sulfone $1^{11 \mathrm{a}, \mathrm{c}}$ was deprotected in situ and subjected to ligation with a series of azides, following our published protocol ${ }^{11 \mathrm{a}}$ (Scheme 1). It should be noted that the use of 1-phenyl-1 $H$-tetrazol-5-yl propargyl sulfone (propargyl PT-sulfone) was also considered for the synthesis of comparable second-generation Julia-Kocienski reagents. The heteroaryl moiety can influence the selectivity in Julia-Kocienski olefinations, ${ }^{14}$ e.g. olefinations of $n$ alkanals with alkyl PT-sulfones proceed with superior selectivity as compared to benzothiazole-derived sulfones. ${ }^{18}$ However, it has been reported that TMS-protected propargyl PT-sulfone is unstable. ${ }^{19}$ This sulfone on reaction with benzaldehyde gave the
enyne product in a low yield, plausibly due to its instability. ${ }^{20}$ Because our protocol requires initial fluorination of a TMS-protected propargyl heteroaryl sulfone, followed by CuAAC reactions, we chose the more stable benzothiazolyl derivative (Scheme 1).

Briefly, in situ alkyne deprotection with $\mathrm{AgBF}_{4}$, followed by $\mathrm{Cu}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{4} \mathrm{PF}_{6}$ mediated reaction with nine azides furnished corresponding triazoles in 66-93\% yield (2-10, Scheme 1). Azidobenzene and 1-azido-4-nitrobenzene gave triazole products $\mathbf{2}$ and $\mathbf{6}$ in $79 \%$ and $82 \%$ yield, respectively, whereas electron-rich aromatic azides gave triazoles $\mathbf{3}-\mathbf{5}$ in slightly higher $90-93 \%$ yields. 1-Azidoadamantane and 1-azidodecane gave products $\mathbf{7}$ and $\mathbf{8}$ in $85 \%$ and $81 \%$ yield, respectively, and 3-(azidopropyl)benzene gave triazole 9 in a slightly lower $68 \%$ yield. Azidoferrocene reacted as well, to give product 10 in a respectable $66 \%$ yield. Reactions were typically complete in $1.5-4 \mathrm{~h}$, except in the case of 2-azidonaphthalene and 1-azido-4-nitrobenzene, where longer reaction times were required ( 19 h and 50 h , respectively).

Screening of olefination conditions was then performed using $N$ - $p$-methoxyphenyl triazolyl Julia-Kocienski reagent 4 and 2-naphthaldehyde (Table 1).

In our prior communication we have demonstrated that condensations of $\mathbf{4}$ and $\mathbf{9}$ with some aldehydes proceeded with $Z$-selectivity, in low-temperature LHMDS-mediated condensations in DMF-DMPU. ${ }^{11 \mathrm{a}}$ In the present case as well, 2-naphthaldehyde reacted with $\mathbf{4}$ to furnish fluorovinyl triazole $(E / Z)$ - $\mathbf{1 1}$ with high $Z$-selectivity (Table 1, entry $1, E / Z$ 7/93). However, when reaction was performed with LHMDS in THF and in the presence of $\mathrm{MgBr}_{2}$, no product formation was observed even after 51 h (entry 2). We were now curious to assess whether condensations would proceed under milder conditions. Indeed, the use of DBU as base in DMF at $-55^{\circ} \mathrm{C}$ gave $(E / Z)-\mathbf{1 1}$, but with a lower $Z$-selectivity than the reaction with LHMDS (compare entry 3 to entry 1). A DBU-mediated reaction in DMFDMPU at $-78^{\circ} \mathrm{C}$ gave selectivity comparable to entry 3 , but the reaction was incomplete after 24 h (entry 4). We were pleased that these reactions could be tuned to $E$-selectivity upon changing the solvent to THF. However, this reaction was incomplete even after 50 h (entry $5, E / Z 63 / 37$ ). When the reaction was performed at $\mathrm{rt}, E$-selectivity improved and the reaction was complete within 10 h (entry $6, E / Z 77 / 23,77 \%$ yield). Further increase in temperature to $50^{\circ} \mathrm{C}$ gave the same $E / Z$ ratio, but in a shorter reaction time (entry 7). At reflux, reaction was complete in 2.5 h (entry $8, E / Z 78 / 22,74 \%$ yield). In the presence of $\mathrm{MgBr}_{2}$, the $E / Z$ ratio dropped to $69 / 31$ (entry 9). Reaction in $\mathrm{CHCl}_{3}$ at reflux gave a similar $E / Z$ ratio $75 / 25$ as compared to the reaction in THF, but a longer reaction time was required (compare entry 10 to entry 8 ).

Having determined conditions that allowed olefinations to be tuned towards $Z$ - or $E$ selectivity, we next assessed the scope of condensations with regard to the carbonyl compound and the structure of the Julia-Kocienski reagent. For this, we performed condensation reactions with three Julia-Kocienski reagents 4, 6, and 9 under two sets of conditions, i.e. with DBU in refluxing THF (Method A, Table 2), and with LHMDS in DMF-DMPU at $-78^{\circ} \mathrm{C}$ (Method B, Table 2).

Under DBU-mediated conditions, all reactions proceeded with $E$-selectivity. Selectivity appears to depend on the aldehyde, and to a lesser extent on the triazole reagent. Good $E$ selectivity was observed with electron-rich aromatic aldehydes (entry 8 in Table 1 and entries 1-3 in Table 2), whereas $E$-selectivity was moderate to poor with increasing electron deficiency in the aldehydes, and with alkanals (entries 5-14, Table 2). Alpha braching in the aldehyde did not alter the $E / Z$ ratio (compare entry 9 to 12 ). In the case of aromatic aldehydes, yields were in the range of $74-87 \%$ (entry 8 in Table 1, and entries $1-3$ and 6-8 in Table 2), except for the reaction of $p$-trifluoromethylbenzaldehyde with sulfone 4 , where product 16 was obtained in moderate $52 \%$ yield (entry 5). $n$-Octanal gave products in moderate (entries 9 and 11) to poor yield (entry 10). 2-Ethylbutanal reacted with sulfone 4 to give product in $47 \%$ yield (entry 12), whereas reactions with sulfones 6 and 9 gave only traces of products (entries 13, 14). It is plausible that in the case of enolizable aldehydes, yields were low due to a competing aldol reaction. Consistent with this, yields were lower with 2-ethylbutanal compared to $n$-octanal, where steric hindrance likely results in slower addition of the Julia reagent to the aldehyde and subsequent spirocyclization.

LHMDS-mediated condensations proceeded with complementary $Z$-selectivity (Table 2). As with the DBU-mediated reactions, this selectivity depended on the structure of the aldehyde, and to a much lesser extent on that of the sulfone. Selectivity was good to excellent with electron-rich aldehydes and the sterically hindered 2-ethylbutanal, and moderate to good with electron-deficient aromatic aldehydes and $n$-octanal. These condensations were very fast and complete disappearance of the aldehyde was observed within 5 minutes at $-78{ }^{\circ} \mathrm{C}$.

Next, reactivity of triazole-derived Julia-Kocienski reagents with ketones was tested as well. For this, $N$-p-methoxyphenyl (4), $N$-(3-phenylpropyl) (9), and $N$-ferrocenyl (10) derived reagents were reacted with three ketones. Table 3 shows yields, $E / Z$ ratios, and ${ }^{19} \mathrm{~F}$ chemical shifts of the products.

All reactions proceeded under LHMDS-mediated conditions, in THF at $0^{\circ} \mathrm{C}$, to give fluorovinyl triazoles 26-30 in 58-87\% yields (Table 3). Initially, condensations were performed using conditions that were employed with aldehydes, i.e. with LHMDS in DMFDMPU at $-78^{\circ} \mathrm{C}$, but incomplete conversions of the starting ketone were observed. Complete conversions were achieved upon warming of the reaction mixture to room temperature, however, yields were lower in DMF-DMPU. For example, addition of LHMDS to a solution of acetophenone and $\mathbf{9}$ in DMF-DMPU at $-78{ }^{\circ} \mathrm{C}$ with subsequent warming to room temperature gave ( $E / Z$ )-29 in $63 \%$ yield. In comparison, a $77 \%$ yield was obtained when the reaction was performed in THF at $0^{\circ} \mathrm{C}$ (entry 4). Stereoselectivity, on the other hand, was similar in both reactions.

In order to assess the stereoselectivity of the condensations with acetophenone, the $E / Z$ isomers produced in the reaction of $N$-(3-phenylpropyl) derived Julia-Kocienski reagent 9 (Table 3, entry 4) with acetophenone were chromatographically separated and the major isomer was crystallized. Analysis by X-ray diffraction ${ }^{21}$ showed the stereochemistry of the major isomer to be Z-29 (Figure 2). The X-ray structure also confirmed regioselectivity of the azide-alkyne cycloaddition reaction.

The $Z$-stereoselectivity observed in the reaction of sulfone 9 with acetophenone is consistent

#### Abstract

with that observed in LHMDS-mediated reactions of aldehydes (Table 2, Method B). We

 assessed the stereochemistry in $E-28$ and $Z-28$, formed by reaction of sulfone $\mathbf{4}$ with acetophenone (Table 3, entry 3), by comparison to NMR characteristics of $E$ - and $Z-29$ (Table 4).In comparing the ${ }^{1} \mathrm{H}$ NMR spectra of $E$ - and $Z-\mathbf{2 9}$, a distinctive 1.11 ppm difference was observed in the chemical shifts of the $\mathrm{H}-5$ triazolyl proton singlets, and the triazolyl proton resonance in $Z-29$ (the major isomer) appeared most downfield in the spectrum (Table 4). The ${ }^{19} \mathrm{~F}$ resonance of the major isomer of $Z-29$ is more upfield shifted as compared to the $E$ isomer (see data in Table 3). In comparing the NMR data of $E / Z$-isomers of compound 29 to those of $\mathbf{2 8}$, a similar 1.13 ppm difference was observed between the chemical shifts of the triazolyl H-5 proton singlets in the major and the minor isomers of olefins 28. Also, the ${ }^{1} \mathrm{H}$ NMR of the major isomer showed an aromatic singlet as the most downfield shifted resonance. Furthermore, in the ${ }^{19} \mathrm{~F}$ NMR, the major isomer in olefin mixture $\mathbf{2 8}$ produced the more upfield resonance. Due to the close structural similarities of $(E / Z)$-28 and ( $E / Z$ )-29 and the parallels in the NMR spectra, the major isomer of $\mathbf{2 8}$ was assigned a $Z$-geometry and the minor isomer $E$. The condensation product from indanone (30) is structurally very different to postulate the olefin stereochemistry by such comparisons. Moreover, because formation of only one isomer was detected, comparison of chemical shifts was not possible.

## Conclusions

In conclusion, a highly modular approach to $N$-substituted 4-(1-fluorovinyl)triazoles has been developed, where $N l$-substituent as well as substituents at the double bond can be readily varied. Cu-catalyzed azide-alkyne ligation reactions of TMS-protected afluoropropargyl benzothiazole sulfone, a Julia-Kocienski reagent, proceed with aryl, alkyl, or metallocenyl azides, to give triazole-derived second-generation Julia-Kocienski reagents in good to excellent yields. Condensation reactions of triazole-derived Julia-Kocienski reagents with aldehydes are tunable and proceed with either $E$-selectivity under mild DBUmediated conditions in THF at reflux, or with $Z$-selectivity in low temperature LHMDSmediated reactions in DMF-DMPU. Ketones react in the presence of LHMDS in THF, to give tetrasubstituted olefins. In the cases studied, where both isomers were formed in reactions with ketones, $E$ - and $Z$-fluorovinyl triazoles were separable under chromatographic conditions. The method offers high flexibility for diversification of $N 1$ and vinyl substituents.

## Experimental Section

General Experimental Considerations-THF was distilled over $\mathrm{LiAlH}_{4}$ and then over sodium, toluene was distilled over sodium, and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was distilled over $\mathrm{CaCl}_{2}$. DMF and DMPU were obtained from commercial sources and were used without further purification. For reactions performed in a nitrogen atmosphere, glassware was dried with heat gun under vacuum. LDA ( 2.0 M solution in heptane/THF/EtPh) and LHMDS (1.0 M in THF) were obtained from commercial sources. All other reagents were obtained from commercial sources and were used as received. 1-Azidoadamantane and $N$-fluorobenzenesulfonimide
(NFSI) are commercially available. Synthesis of 2-[1-fluoro-3-(trimethylsilyl)prop-2ynylsulfonyl]benzo[ $d$ ]thiazole (1) was first reported in our preliminary communication, ${ }^{11 \mathrm{a}}$ we then reported an improved method. ${ }^{11 \mathrm{c}}$ Syntheses of 2-\{fluoro[1-(4-methoxyphenyl)-1 $H$-1,2,3-triazol-4-yl]methylsulfonyl\}benzo[d]-thiazole (4), 2-[(1-decyl-1 $H$-1,2,3-triazol-4-yl)fluoromethylsulfonyl]benzo[ $d$ ]thiazole (8) and 2-\{fluoro[1-(3-phenylpropyl)-1 H -1,2,3-triazol-4-yl]methylsulfonyl $\}$ benzo[ $d]$-thiazole (9) have been reported in our preliminary communication. ${ }^{11 \mathrm{a}}$ 1-Azido-4-phenoxybenzene, ${ }^{22 \mathrm{a}} 1$-azido-4nitrobenzene, ${ }^{22 \mathrm{a}}$ azidobenzene, ${ }^{22,23}$ 2-azidonaphthalene, ${ }^{23}$ azidoferrocene, ${ }^{24}$ 1-azido-4methoxybenzene, ${ }^{11 \mathrm{a}, 22} 3$-(azidopropyl)benzene, ${ }^{11 \mathrm{a}}$ and 1 -azidodecane ${ }^{11 \mathrm{a}}$ were synthesized via literature methods. Thin layer chromatography was performed on glass-backed silica gel plates $(250 \mu \mathrm{~m})$. Column chromatographic purifications were performed on 200-300 mesh silica gel. ${ }^{1} \mathrm{H}$ NMR spectra were recorded at 500 MHz and were referenced to residual protio solvent. ${ }^{13} \mathrm{C}$ NMR spectra were recorded at 125 MHz and were referenced to the carbon resonance of the deuterated solvent. ${ }^{19} \mathrm{~F}$ NMR spectra were recorded at 282 MHz with $\mathrm{CFCl}_{3}$ as the internal standard. Chemical shifts $(\delta)$ are reported in parts per million and coupling constants $(J)$ are in hertz $(\mathrm{Hz})$. HRMS data were obtained using a TOF analyzer, the ionization modes are specified under each compound heading.

## Synthesis of Triazoles

General procedure-To a stirring solution of azide (1 molar equiv) in $4: 1(\mathrm{v} / \mathrm{v}) \mathrm{CH}_{2} \mathrm{Cl}_{2}$ / MeOH ( $28.0 \mathrm{~mL} / \mathrm{mmol}$ of azide), 2-[1-fluoro-3-(trimethylsilyl)prop-2ynylsulfonyl]benzo[d]thiazole $\mathbf{1}$ ( 1.10 to 1.50 molar equiv), $\mathrm{Cu}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{4} \mathrm{PF}_{6}(0.20$ molar equiv) and $\mathrm{AgBF}_{4}$ ( 0.20 molar equiv) were sequentially added. The stirring was continued at room temperature until TLC showed disappearance of the azide. The solvents were evaporated under reduced pressure and the crude reaction mixture was purified by column chromatography on silica gel. The quantities of azides and fluoropropargyl sulfone $\mathbf{1}$, reaction times, eluting solvents for chromatography, product yields, $R_{\mathrm{f}}$ values, and spectroscopic characterization data are provided under the individual compound headings.

## General procedures for condensations of sulfones 4, 6, and 9 with aldehydes

Method A: DBU-mediated condensations: To a stirring solution of the aldehyde (1 molar equiv) and sulfone (1.2-1.7 molar equiv, see specific compound headings for the stoichiometry) in THF ( $20 \mathrm{~mL} / \mathrm{mmol}$ of aldehyde), DBU ( 4 molar equiv) in THF ( $8 \mathrm{~mL} /$ mmol of aldehyde) was added. The reaction mixture was stirred at reflux and monitored for disappearance of the aldehyde. If disappearance of sulfone was observed prior to consumption of the aldehyde, more sulfone was added to the reaction mixture and the reaction was continued at reflux. Upon complete consumption of the aldehyde, the solvent was removed under reduced pressure. The product $E / Z$ ratio was determined by ${ }^{19} \mathrm{~F}$ NMR, prior to purification by column chromatography. The combined $E / Z$ product mixture was purified by column chromatography over silica gel. The quantities of reactants and solvents,
reaction times, eluting solvents for chromatography, product yields, $R_{\mathrm{f}}$ values, and spectroscopic data are provided under the individual compound headings.

Method B: LHMDS-mediated condensations: A stirring solution of aldehyde (1 molar equiv) and sulfone ( 1.2 molar equiv) in $1: 1(\mathrm{v} / \mathrm{v})$ DMF-DMPU ( $15.2 \mathrm{~mL} / \mathrm{mmol}$ of aldehyde) was cooled to $-78{ }^{\circ} \mathrm{C}$ (dry ice $/ \mathrm{iPrOH}$ ), under a nitrogen atmosphere. LHMDS ( 1.0 M solution in THF, 2.40 molar equiv) was then added to the mixture. The reaction mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 5 min , saturated aq $\mathrm{NH}_{4} \mathrm{Cl}$ was added, and the mixture was poured into EtOAc. The organic layer was separated and the aqueous layer was extracted with EtOAc $(3 \times)$. The combined organic layer was washed with water and brine, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and evaporated under reduced pressure. The product $E / Z$ ratio was determined by ${ }^{19} \mathrm{~F}$ NMR, prior to purification by column chromatography. The combined $E / Z$ product mixture was purified by column chromatography over silica gel. The quantities of reactants and solvents, eluting solvents for chromatography, product yields, $R_{\mathrm{f}}$ values, and spectroscopic data are provided under the individual compound headings.

General procedure for condensations of sulfones 4,9 , and 10 with ketones: A stirring solution of the ketone ( 1 molar equiv) and sulfone (1.2-1.3 molar equiv) in THF ( $12 \mathrm{~mL} /$ mmol of ketone, except for compound 30, see below) was cooled to $0^{\circ} \mathrm{C}$ under a nitrogen atmosphere. LHMDS ( 2.40 molar equiv in every case and 4.0 molar equiv for compound $\mathbf{3 0}$, see below) was added to the mixture. The reaction mixture was then stirred at $0^{\circ} \mathrm{C}$ and was
monitored for disappearance of the ketone. Saturated aq $\mathrm{NH}_{4} \mathrm{Cl}$ was added and the mixture was poured into EtOAc. The organic layer was separated and the aqueous layer was extracted with EtOAc ( $3 \times$ ). The combined organic layer was washed with water and brine, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and evaporated under reduced pressure. The product $E / Z$ ratio was determined by ${ }^{19} \mathrm{~F}$ NMR, prior to purification by column chromatography. The combined $E / Z$ product mixture was isolated by column chromatography over silica gel. The quantities of reactants and solvents, reaction times, eluting solvents for chromatography, product yields, $R_{\mathrm{f}}$ values, and spectroscopic data are provided under the individual compound headings.

Chromatography was performed using $20 \% \mathrm{EtOAc}$ in hexanes, with stepwise increase to $40 \%$ EtOAc in hexanes, and compound 30 was obtained as a yellow-orange solid $(35.1 \mathrm{mg}, 58 \%) . R_{f}(40 \% \mathrm{EtOAc}$ in hexanes $)=0.48$. Formation of only one isomer was detected by ${ }^{1} \mathrm{H}$ and ${ }^{19} \mathrm{~F}$ NMR, and olefin stereochemistry was not determined. ${ }^{1} \mathrm{H}$ NMR ( 500 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 7.91(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Ar}-\mathrm{H}, J=6.8 \mathrm{~Hz}), 7.90(\mathrm{~s}, 1 \mathrm{H}), 7.32(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Ar}-\mathrm{H}, J=6.4 \mathrm{~Hz})$, 7.29-7.24 (m, 2H), 4.88 (t, 2H, $J=1.9 \mathrm{~Hz}$ ), 4.30 (t, 2H, $J=1.9 \mathrm{~Hz}), 4.25$ (s, 5H), 3.34 (td, $2 \mathrm{H}, J=6.8 ; 2.4 \mathrm{~Hz}$ ), 3.17 (br t, $2 \mathrm{H}, J=7.3 \mathrm{~Hz}$ ). ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 146.8$, $143.9\left(\mathrm{~d},{ }^{1} J_{\mathrm{CF}}=236.2 \mathrm{~Hz}\right), 143.6\left(\mathrm{~d}, J_{\mathrm{CF}}=38.0 \mathrm{~Hz}\right), 139.1\left(\mathrm{~d}, J_{\mathrm{CF}}=2.7 \mathrm{~Hz}\right), 128.4\left(\mathrm{~d}, J_{\mathrm{CF}}\right.$ $=2.3 \mathrm{~Hz}), 127.0,126.0\left(\mathrm{~d}, J_{\mathrm{CF}}=14.2 \mathrm{~Hz}\right), 125.1,124.0\left(\mathrm{~d}, J_{\mathrm{CF}}=11.0 \mathrm{~Hz}\right), 120.2,93.7$, $70.5,67.0,62.4,31.3,28.3\left(\mathrm{~d}, J_{\mathrm{CF}}=5.5 \mathrm{~Hz}\right) .{ }^{19} \mathrm{~F}$ NMR ( $282 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta-123.76(\mathrm{~s})$. Single-Crystal X-ray Diffraction for (Z)-29—The intensity data for (Z)-29 were measured on a KappaCCD diffractometer (graphite-monochromated Mo $K a$ radiation, $\lambda=$ $0.71073 \AA, \varphi-\omega$ scans) at $100(1) \mathrm{K}$. The data were not corrected for absorption. Details of the solution and refinements for $\mathrm{C}_{20} \mathrm{H}_{20} \mathrm{FN}_{3}(Z-29)$ are as follows. The crystals of ( $Z$ )-29,
with approximate dimensions $0.10 \times 0.28 \times 0.30 \mathrm{~mm}$, were monoclinic with space group $P 2 / c$. The final unit-cell constants of $(Z)-29$ were $a=18.306(4) b=5.6030(11), c=$ 16.578(3) A, $\beta=101.41(3)^{\circ}, V=1666.8$ (6) $\AA^{3}, Z=4, \rho=1.281 \mathrm{~g} \mathrm{~cm}^{-1}, \mu=0.085 \mathrm{~mm}^{-1}$, formula weight $=321.39$. The structure of Z-29 was solved with SHELXS-97 and refined by full-matrix least squares on $F^{2}$ with SHELXL-97. The hydrogen atoms were calculated with the riding model in the structure-factor calculations, but their parameters were not refined. The final discrepancy indices, $2.95<\theta<27.47^{\circ}$, were $R=0.0610$ (calculated on $F$ for 2290 reflections) and $R_{W}=0.1395$ (calculated on $F^{2}$ for all 3804 reflections) with 219 parameters varied. The major peaks of the final difference map are -0.29 and +0.22 e $\AA^{3}$.
