

# Effect of Taxane Plus Platinum Regimens vs Doxorubicin Plus Cisplatin as Adjuvant Chemotherapy for Endometrial Cancer at a High Risk of Progression

## A Randomized Clinical Trial

[+ Supplemental content](#)

**IMPORTANCE** The efficacy of taxane plus platinum regimens has been demonstrated for advanced or recurrent endometrial cancer; however, it has not been assessed in postoperative adjuvant chemotherapy for endometrial cancer.

**OBJECTIVE** To evaluate the clinical benefit of taxane plus platinum compared with standard doxorubicin plus cisplatin as postoperative adjuvant chemotherapy in endometrial cancer.

**DESIGN, SETTING, AND PARTICIPANTS** In this multicenter, open-label, phase 3 randomized clinical trial, patients with endometrial cancer at high-risk stage I or II or stage III or IV that did not extend beyond the abdominal cavity and had 2 cm or greater residual tumor were included from 118 institutions in Japan from November 24, 2006, to January 7, 2011. Data was analyzed from March 15, 2017, to June 30, 2017.

**INTERVENTIONS** Eligible patients were randomly assigned (1:1:1) to receive 6 cycles of doxorubicin, 60 mg/m<sup>2</sup>, plus cisplatin, 50 mg/m<sup>2</sup>, on day 1; docetaxel, 70 mg/m<sup>2</sup>, plus cisplatin, 60 mg/m<sup>2</sup>, on day 1; or paclitaxel, 180 mg/m<sup>2</sup>, plus carboplatin (area under the curve, 6.0 mg/mL × min) on day 1 every 3 weeks.

**MAIN OUTCOMES AND MEASURES** The primary end point was progression-free survival. Secondary end points were overall survival, occurrence of adverse events, tolerability, and status of lymph node dissection.

**RESULTS** Among 788 eligible patients, the median (SD) age was 59 (22-74) years; 263 patients were assigned to doxorubicin plus cisplatin treatment, 263 patients to docetaxel plus cisplatin treatment, and 262 patients to paclitaxel plus carboplatin treatment. The number of patients who did not complete 6 cycles was 53 (20.1%) for the doxorubicin plus cisplatin group, 45 (17.1%) for the docetaxel plus cisplatin group, and 63 (24.0%) for the paclitaxel plus carboplatin group. Tolerability of these regimens were not statistically different. After a median follow-up period of 7 years, there was no statistical difference of progression-free survival (doxorubicin plus cisplatin, 191; docetaxel plus cisplatin, 208; paclitaxel plus carboplatin, 187;  $P = .12$ ) or overall survival (doxorubicin plus cisplatin, 217; docetaxel plus cisplatin, 223; paclitaxel plus carboplatin, 215;  $P = .67$ ) among the 3 groups. The 5-year progression-free survival rate was 73.3% for the doxorubicin plus cisplatin group, 79.0% for the docetaxel plus cisplatin group, and 73.9% for the paclitaxel plus carboplatin group, while the 5-year overall survival rates were 82.7%, 88.1%, and 86.1%, respectively.

**CONCLUSIONS AND RELEVANCE** There was no significant difference of survival among patients receiving doxorubicin plus cisplatin, docetaxel plus cisplatin, or paclitaxel plus carboplatin as postoperative adjuvant chemotherapy for endometrial cancer. Because each regimen showed adequate tolerability but different toxic effects, taxane plus platinum regimens may be a reasonable alternative to treatment with doxorubicin plus cisplatin.

Initial treatment for endometrial cancer is surgery, including total hysterectomy. Risk factors for recurrence include deep myometrial invasion, cervical stromal invasion, lymphovascular invasion, tumor histology, extrauterine progression, and distant metastasis.<sup>1</sup> For patients with risk factors, postoperative adjuvant therapy is indicated to reduce the risk of recurrence. In patients with early disease, postoperative radiotherapy has been shown to reduce local recurrence, but a survival benefit has not been demonstrated.<sup>2-6</sup> In patients with advanced disease, postoperative systemic chemotherapy was shown to have a survival benefit comparable with radiotherapy.<sup>7</sup>

For advanced or recurrent endometrial cancer, doxorubicin plus cisplatin has been the standard treatment regimen.<sup>8,9</sup> From the results of GOG122,<sup>7</sup> doxorubicin plus cisplatin is also recommended as the standard treatment regimen for adjuvant chemotherapy. More recently, taxanes such as paclitaxel and docetaxel were reported to be effective,<sup>10,11</sup> and paclitaxel has been combined with platinum to form paclitaxel with doxorubicin plus cisplatin<sup>12</sup> and paclitaxel plus carboplatin.<sup>13</sup> The interim analysis of the GOG209 study<sup>14</sup> showed the noninferiority of paclitaxel plus carboplatin to paclitaxel with doxorubicin plus cisplatin. However, the role of taxanes plus platinum as adjuvant chemotherapy has not been well established. A phase 2 study<sup>15</sup> was conducted to investigate various taxane plus platinum therapies for treatment of advanced or recurrent endometrial cancer to explore the clinical effects available as adjuvant therapy. The response rate achieved with paclitaxel plus carboplatin, docetaxel plus cisplatin, and docetaxel plus carboplatin were better than that of doxorubicin plus cisplatin as historical control. Among these regimens, paclitaxel plus carboplatin and docetaxel plus cisplatin were considered to warrant further exploration in a phase 3 study.

Establishment of evidence and validation of the optimal postoperative adjuvant chemotherapy regimen for endometrial cancer are important issues. We conducted a phase 3 randomized clinical trial to compare taxane plus platinum with doxorubicin plus cisplatin in patients with endometrial cancer that had risk factors for progression after surgery.

## Methods

### Study Design

This multicenter, open-label, phase 3 randomized clinical trial was performed to determine if docetaxel plus cisplatin or paclitaxel plus carboplatin was superior to doxorubicin plus cisplatin or each other as adjuvant chemotherapy in patients with endometrial cancer at a high risk of progression following surgery. The primary end point was progression-free survival (PFS), and the secondary endpoints were overall survival, occurrence of adverse events (AEs), tolerability of treatment, and status of lymph node dissection. This study was designed by the Japanese Gynecologic Oncology Group (JGOC) (protocol number: JGOG2043) and carried out by JGOG institutions.

### Patients

Eligible patients had histologically confirmed endometrial cancer that was classified as having a high risk of progression. Cancer with a high risk of progression was defined as being in stages

## Key Points

**Question** Will taxane plus platinum regimens show superiority over standard doxorubicin plus cisplatin in postoperative adjuvant chemotherapy treatment of patients with high-risk early stage or optimally debulked advanced-stage endometrial cancer?

**Findings** This multicenter, phase 3 randomized clinical trial provides an analysis of progression-free survival in 788 patients on postoperative taxane plus platinum regimens, including docetaxel plus cisplatin or paclitaxel plus carboplatin, as compared with doxorubicin plus cisplatin. Taxane plus platinum regimens did not demonstrate a survival benefit over doxorubicin plus cisplatin, though they were well tolerated and had different profiles of toxicities from that of doxorubicin plus cisplatin.

**Meaning** This study indicates that taxane plus platinum regimens can be an alternative to doxorubicin plus cisplatin in adjuvant chemotherapy for patients with endometrial cancer that has risk factors for progression.

I or II<sup>16</sup> with myometrial invasion exceeding half and histologic grade 2 or 3 (including poor prognosis histologic types such as serous, clear cell, and undifferentiated), as well as stage III and IV cancers without metastasis beyond the abdominal cavity. Other inclusion criteria were (1) patients who had undergone total abdominal hysterectomy with bilateral salpingo-oophorectomy and pelvic lymph node dissection in which the residual tumor was 2 cm or less, (2) patients scheduled to receive chemotherapy within 8 weeks postsurgery, (3) patients without prior chemotherapy or radiotherapy, (4) patients aged between 20 and 74 years at registration, (5) patients having an Eastern Cooperative Oncology Group performance status of 0 to 2, and (5) patients with adequate function of major organs (eg, bone marrow, heart, liver, kidneys). Patients were excluded if they had sarcomatous component, serious complications, concurrent infection, or a simultaneous cancer or a history of other cancer within the past 5 years.

Written informed consent was obtained from all patients prior to enrollment in the study. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki, and the protocol was approved by the institutional review board of each participating clinical site prior to patient enrollment.

### Randomization and Treatment

Eligible patients were randomly allocated by the JGOG data center to 1 of 3 groups at a 1:1:1 ratio using surgical stage (I or II vs III or IV) and tumor histology (G1 or G2 vs G3 or histology with a poor prognosis) as stratification factors. For the doxorubicin plus cisplatin regimen, doxorubicin, 60 mg/m<sup>2</sup>, was administered intravenously followed by intravenous infusion of cisplatin, 50 mg/m<sup>2</sup>, over at least 2 hours on day 1. For the docetaxel plus cisplatin regimen, docetaxel, 70 mg/m<sup>2</sup>, was infused over 1 to 2 hours followed by intravenous infusion of cisplatin, 60 mg/m<sup>2</sup>, over at least 2 hours on day 1. For the paclitaxel plus carboplatin regimen, paclitaxel, 180 mg/m<sup>2</sup>, was infused over 3 hours followed by intravenous infusion of carboplatin (area under the curve, 6 mg/mL × min) over at least 1 hour on day 1. For calculation of doses, the upper limit of the body surface area was set as 2.0 m<sup>2</sup>. The

dose of carboplatin was calculated by Calvert formula using the glomerular filtration rate as determined by Jelliffe formula, and the upper limit was set at 1000 mg. Treatment was repeated every 3 weeks for a total of 6 cycles unless disease progression or unacceptable toxicity was observed. After completion of treatment, new anticancer therapy was not permitted unless recurrence or progression occurred.

The protocol allowed the timing of administration and drug doses to be changed in accordance with predefined rules. Administration could be delayed up to 3 weeks to allow recovery from AEs. The dose could be reduced by about 20% and up to twice depending on the severity of AEs.

### Study Assessments

Progression-free survival was defined as the time to recurrence, progression, or death from any cause, with the date of study registration for randomization being day 1. Overall survival was defined as time to death from any cause, with the date of study registration for randomization being day 1. Patients without such events or patients lost to follow-up were censored at the latest survival date. Follow-up investigation was performed every 6 months for at least 5 years.

Adverse events were documented from start of study treatment through 30 days after the last treatment and were assessed and collected based on the National Cancer Institute's Common Terminology Criteria for Adverse Events, version 3.0. To assess treatment status, the following information was recorded: (1) dose reduction, delay, or discontinuation and the reasons; (2) actual total dose administered; and (3) relative dose intensity. Relative dose intensity was calculated as the ratio of the actual total dose delivered to the predicted total dose. The number of lymph nodes dissected was also summarized.

### Statistical Analysis

In accordance with the intention-to-treat principle, all randomized patients were used for efficacy analysis. The goal of this study was to perform all pairwise comparisons among 3 groups based on the primary end point, PFS. To avoid multiplicity for all of the 3 pairwise tests, the following testing procedure was planned in this study. First, the global null hypothesis (eg, the PFS functions in all 3 groups were identical) was tested using log-rank test with 2-sided  $P = .05$  considered statistically significant. Second, only when the global null hypothesis was rejected, all pairwise comparisons among the 3 groups were performed using log-rank with 2-sided  $P = .05$  considered statistically significant.

Using data from a previous study,<sup>17</sup> it was estimated that the 5-year PFS would be about 75% for patients on the doxorubicin plus cisplatin regimen. Based on the results of previous studies,<sup>15,17</sup> if the hazard ratio (HR) of the current study treatment (docetaxel plus cisplatin or paclitaxel plus carboplatin) vs doxorubicin plus cisplatin for PFS is 63%, the study treatment would be considered clinically significant. To robustly detect these clinical improvements with 80% power, which is defined by the probability that the global null hypothesis and any paired null hypotheses were rejected simultaneously, under the aforementioned procedure in an enrollment period of 4 years and a follow-up period of 5 years, 250 patients per treatment group were required

in 10 000 simulation studies. The recruitment target was 260 patients with 10 dropouts per treatment group.

Progression-free survival and overall survival curves were estimated by the Kaplan-Meier method. Subgroup analysis of PFS was carried out using a Cox proportional hazards model to examine the effect of patient demographic factors on the treatment effect. All patients who received at least one dose of the study treatment were included in the safety analysis. To assess AEs, the number of patients with AEs of each grade, the number with grade 3 or higher AEs, and the incidence proportions were calculated for each treatment group. A Mantel-Haenszel test was performed for intergroup comparisons with 2-sided  $P = .05$  considered statistically significant. To assess treatment status, intergroup comparison of each parameter was performed using Fisher exact tests. Statistical analyses were carried out using SAS, version 9.3 (SAS Institute Inc).

## Results

### Subjects

A total of 788 patients were enrolled at 118 clinical sites from November 24, 2006, through January 7, 2011. Patients were randomized as follows: 263 patients to the doxorubicin plus cisplatin treatment group, 263 patients to the docetaxel plus cisplatin treatment group, and 262 patients to the paclitaxel plus carboplatin treatment group. These patients were subjected to efficacy analysis. Seven patients did not receive chemotherapy, and safety analysis was performed in 781 patients after excluding these patients. Patient disposition is shown in **Figure 1**. Baseline characteristics were balanced among the 3 treatment groups, as summarized in eTable 1 in the **Supplement**. Most patients had endometrioid carcinoma and no residual tumor. In 454 of 788 (57.6%) patients, both pelvic and para-aortic lymph node dissection were performed.

The median number (range) of dissected lymph nodes was 24 (1-83) in the pelvic region and 13 (1-67) in the para-aortic region. Pelvic lymph node metastasis was observed in 257 (32.7%) patients, while para-aortic lymph node metastasis was found in 122 (15.5%) patients. Lymph node metastasis was detected in 93 (35.4%) patients from the doxorubicin plus cisplatin group, 95 (36.1%) patients from the docetaxel plus cisplatin group, and 93 (35.5%) patients from the paclitaxel plus carboplatin group.

### Efficacy

The final analysis was carried out after data cutoff on January 7, 2016. In the intention-to-treat analysis set ( $n = 788$ ), the median follow-up period was 7 years. During the observation period, 202 patients showed progression or death. Death was confirmed for 133 patients. The 5-year PFS was 73.3% in the doxorubicin plus cisplatin group, 79.0% in the docetaxel plus cisplatin group, and 73.9% in the paclitaxel plus carboplatin group, with no significant differences among the 3 groups (2-sided  $P = .12$ ) (**Figure 2A**). Because uniformity of the PFS hazard among the 3 groups was not rejected, comparison of PFS between each pair of groups was not completed.

To identify subgroups responding to each study treatment, PFS was analyzed in various patient subpopulations (**Figure 3**).

Figure 1. Randomization and Follow-up of Participants

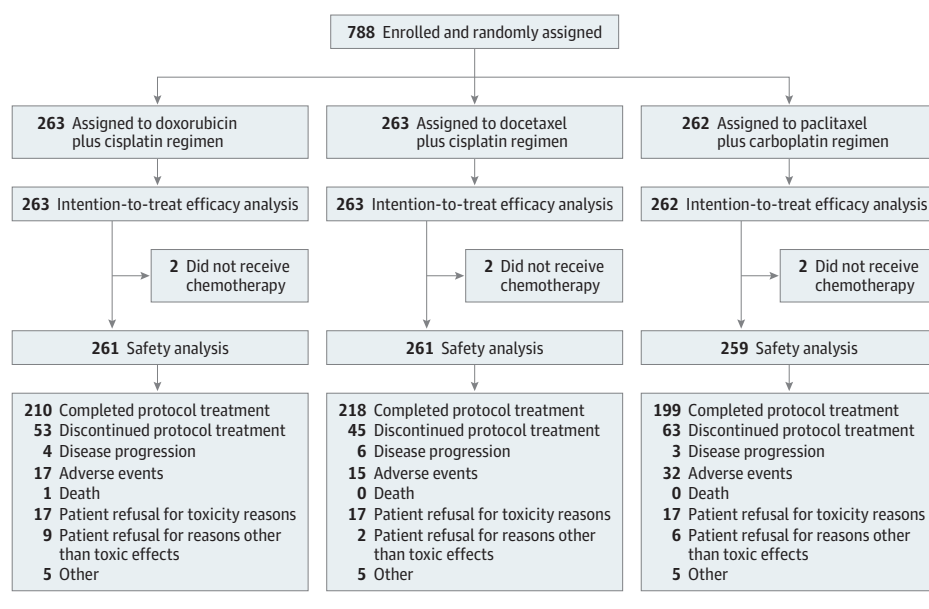

Figure 2. Progression-Free Survival and Overall Survival of the Study Cohort

Following a 2-sided log-rank test after a median follow-up period of 7 years, among patients in the doxorubicin plus cisplatin (AP) treatment group, docetaxel plus cisplatin (DP) treatment group, and paclitaxel plus carboplatin (TC) treatment group, there was no statistical difference of progression-free

survival (A) (AP, 72 of 263 patients; DP, 55 of 263 patients; TC, 75 of 262 patients;  $P = .12$ ) nor overall survival (B) (AP, 46 of 263 patients; DP, 40 of 263 patients; TC, 47 of 262 patients;  $P = .67$ ).

Compared with the doxorubicin plus cisplatin group, the patient subpopulations with better PFS in the docetaxel plus cisplatin group were younger than 70 years (HR, 0.64; 95% CI, 0.43-0.93), had no residual tumor (HR, 0.69; 95% CI, 0.47-0.99), had tumor histologic grade 1 or 2 (HR, 0.54; 95% CI, 0.32-0.91), and were positive for lymph node metastasis (HR, 0.62; 95% CI, 0.39-0.98). Compared with the doxorubicin plus cisplatin group, the patient subpopulation with better PFS in the paclitaxel plus carboplatin group had lymph node metastasis (HR, 0.63; 95% CI, 0.40-0.99). Conversely, the subpopulation with worse PFS in the paclitaxel plus carboplatin group compared with the doxorubicin plus cisplatin group had no lymph node metastasis (HR, 1.63; 95% CI, 1.01-2.61). No significant difference in PFS was found among the 3

groups divided by cancer stages I or II (doxorubicin plus cisplatin, 70 of 80 (87.5%) patients progression free; docetaxel plus cisplatin, 75 of 80 (93.7%) patients progression free; paclitaxel plus carboplatin, 70 of 82 (85.4%) patients progression free;  $P = .23$ ) and by cancer stages III or IV (doxorubicin plus cisplatin, 121 of 183 (66.1%) patients progression free; docetaxel plus cisplatin, 133 of 183 (72.7%) patients progression free; paclitaxel plus carboplatin, 117 of 180 (65.0%) patients progression free;  $P = .29$ ).

The 5-year overall survival was 82.7% in the doxorubicin plus cisplatin group, 88.1% in the docetaxel plus cisplatin group, and 86.1% in the paclitaxel plus carboplatin group with no significant differences among the 3 groups (2-sided  $P = .67$ ) (Figure 2B).

Figure 3. Subgroup Analyses of Progression-Free Survival

### Extent of Exposure

Delivery of treatment is shown in Figure 1. The median number of cycles was 6 (range, 0-6) in all groups. Protocol treatment was discontinued by 53 patients (20.2%; 95% CI, 15.5%-25.5%) in the doxorubicin plus cisplatin group, 45 patients (17.1%; 95% CI, 12.8%-22.2%) in the docetaxel plus

cisplatin group, and 63 patients (24.0%; 95% CI, 19.0%-29.7%) in the paclitaxel plus carboplatin group ( $P = .14$ ). A total of 1419 of 1578 cycles (89.9%; 95% CI, 88.3%-91.4%) were completed in the doxorubicin plus cisplatin group, 1425 of 1578 cycles (90.3%; 95% CI, 88.7%-91.7%) in the docetaxel plus cisplatin group, and 1385 of 1572 cycles

(88.1%; 95% CI, 86.4%-89.7%) in the paclitaxel plus carboplatin group ( $P = .10$ ).

The number of patients in whom treatment was delayed was 188 (72.0%; 95% CI, 66.2%-77.4%) in the doxorubicin plus cisplatin group, 108 (41.4%; 95% CI, 35.3%-47.6%) in the docetaxel plus cisplatin group, and 180 (69.5%; 95% CI, 63.5%-75.1%) in the paclitaxel plus carboplatin group ( $P < .001$ ). The number of treatment cycles delayed because of AEs was 76 (29.0%; 95% CI, 26.7%-31.5%) in the doxorubicin plus cisplatin group, 23 (8.7%; 95% CI, 7.3%-10.3%) in the docetaxel plus cisplatin group, and 60 (23.0%; 95% CI, 20.8%-25.3%) in the paclitaxel plus carboplatin group ( $P < .001$ ). In addition, the number of patients with dose reduction was 77 (29.5%; 95% CI, 24.0%-35.4%) in the doxorubicin plus cisplatin group, 56 (21.5%; 95% CI, 16.6%-26.9%) in the docetaxel plus cisplatin group, and 72 (27.8%; 95% CI, 22.4%-33.7%) in the paclitaxel plus carboplatin group ( $P = .09$ ). A total of 99 of 1419 cycles (7.0%; 95% CI, 5.7%-8.4%) with dose reduction were completed in the doxorubicin plus cisplatin group, 65 of 1425 cycles (4.6%; 95% CI, 3.5%-5.8%) in the docetaxel plus cisplatin group, and 92 of 1385 cycles (6.6%; 95% CI, 5.4%-8.1%) in the paclitaxel plus carboplatin group ( $P = .01$ ).

Mean (SD) relative dose intensity was 86.7% (11.7%) for doxorubicin and 88.5% (10.6%) for cisplatin in the doxorubicin plus cisplatin group, 92.6% (10.3%) for docetaxel and 92.9% (9.9%) for cisplatin in the docetaxel plus cisplatin group, and 86.4% (12.2%) for paclitaxel and 87.5% (11.5%) for carboplatin in the paclitaxel plus carboplatin group. For all of these indices, treatment with docetaxel plus cisplatin was superior to the other treatment groups.

### Safety

One patient died of an AE (suspected myocardial infarction) in the doxorubicin plus cisplatin group. Discontinuation of treatment because of AEs was most frequent in the paclitaxel plus carboplatin group and was required in 17 (6.5%) patients in the doxorubicin plus cisplatin group, 15 (5.7%) patients in the docetaxel plus cisplatin group, and 32 (12.2%) patients in the paclitaxel plus carboplatin group. Treatment-related AEs of grade 3 or higher with a frequency of approximately 5% or greater are summarized for each treatment group in eTable 2 in the [Supplement](#). Leukopenia, neutropenia, febrile neutropenia, and anemia were milder in the docetaxel plus cisplatin group and the paclitaxel plus carboplatin group than in the doxorubicin plus cisplatin group. However, thrombocytopenia was significantly more frequent in the paclitaxel plus carboplatin group. Gastrointestinal symptoms such as anorexia, nausea, vomiting, and diarrhea were more frequent with cisplatin regimen (doxorubicin plus cisplatin and docetaxel plus cisplatin) than with paclitaxel plus carboplatin treatment, while myalgia and neurotoxicity were more frequent with paclitaxel plus carboplatin treatment.

### Discussion

The present study was designed to compare PFS between patients treated with taxane plus platinum regimens (docetaxel plus cisplatin and paclitaxel plus carboplatin) and doxorubicin plus cisplatin, which is standard postoperative adjuvant chemotherapy

for endometrial cancer. Although the superiority of docetaxel plus cisplatin and paclitaxel plus carboplatin over doxorubicin plus cisplatin was not demonstrated, we found that the 3 regimens were comparable in therapeutic effect. The same findings were obtained for overall survival, a secondary end point.

The factors associated with a high risk of progression in this study correspond to intermediate risk, high-intermediate risk, high risk, and part of advanced disease according to the European Society for Medical Oncology/European Society of Gynaecological Oncology/European Society for Radiotherapy and Oncology consensus conference.<sup>1</sup> The indication for adjuvant therapy has varied in other clinical studies. In an Italian study<sup>18</sup> and the JGOG2033 study,<sup>19</sup> patients had stage IC cancer with myometrial invasion exceeding half through stage III. In a study of 2 randomized clinical trials,<sup>17</sup> one trial (NSGO EC-9501/EORTC-55991) enrolled patients who had cancer in stage I, stage II, stage IIIA with positive cytology, and stage IIIC with positive pelvic lymph node metastasis, while the other trial (MaNGO ILIAD-III) enrolled patients who had cancer in stage IIB through III (excluding stage III with positive cytology). In the GOG122 study,<sup>7</sup> patients had stage III cancer with less than 2-cm residual tumor and stage IV cancer. The present study encompassed the patient population investigated in previous phase 3 studies of adjuvant therapy. Accordingly, the results can be extrapolated to the majority of patients who require adjuvant therapy. In this study, 5-year PFS was 73.3% in the doxorubicin plus cisplatin group, and the result was within the expected range. In the Italian study,<sup>17</sup> JGOG2033, and GOG122, 5-year PFS was 63%, 81.8%, and 42%, respectively, for the chemotherapy group.<sup>7,18,19</sup> Integrated analysis of NSGO EC-9501/EORTC-55991 and MaNGO ILIAD-III showed 5-year PFS of 78%, and GOG184 showed 62% to 64% 3-year PFS for the radiation plus subsequent chemotherapy group.<sup>17,20</sup> Thus, the results of the present study were favorable compared with previous investigations of adjuvant therapy.

In previous phase 3 studies, lymph node dissection was only an option for staging,<sup>7,17-20</sup> and lymph node dissection did not extend survival time in patients with early stage cancer.<sup>21,22</sup> On the other hand, the number of dissected lymph nodes was correlated with detection of metastasis and a better prognosis.<sup>23,24</sup> It was also reported that additional para-aortic lymph node dissection might contribute to an improved prognosis,<sup>25,26</sup> and the phase 3 trial to investigate the survival benefit of para-aortic lymph node dissection is in progress.<sup>27</sup> In this study, lymph node dissection may have contributed to improved overall prognosis, thus offsetting the expected differences between regimens. Meanwhile, subpopulation analyses showed that the PFS of patients with lymph node metastasis was better with docetaxel plus cisplatin or paclitaxel plus carboplatin treatments than doxorubicin plus cisplatin treatment. As adjuvant therapy for patients with breast cancer and lymph node metastasis, docetaxel or paclitaxel combined with anthracycline was shown to be effective, which suggests affinity of taxanes for lymph nodes.<sup>28-30</sup> Extensive and careful lymph node dissection plus chemotherapy that includes a taxane may be an effective treatment option for patients with a risk of lymph node metastasis.

The incidence of AEs in each treatment group was comparable with those previously reported.<sup>7-9,15</sup> Doxorubicin plus cisplatin was mainly associated with hematological and gastroin-

testinal toxicities. Neurotoxicity is a dose-limiting toxicity for paclitaxel plus carboplatin, and it showed a similar trend to the toxicity of paclitaxel with doxorubicin plus cisplatin.<sup>12,20,31,32</sup> Docetaxel plus cisplatin was associated with gastrointestinal toxicity, but hematological toxicity was mild. Neutropenia is a dose-limiting toxicity of docetaxel or its combination with carboplatin,<sup>15,33</sup> but it seems to be reduced by docetaxel combined with cisplatin.<sup>34,35</sup> Although the completion rate in this study was similar to or better than in previous studies,<sup>7,18-20</sup> docetaxel plus cisplatin appears to be more tolerated than the other regimens.

## Conclusions

In conclusion, taxane plus platinum regimens did not demonstrate a survival benefit over treatment with doxorubicin plus cisplatin; therefore, doxorubicin plus cisplatin remains the standard postoperative adjuvant chemotherapy regimen for endometrial cancer at a high risk of progression. Nevertheless, considering efficacy and tolerability, taxane plus platinum regimens may be an alternative to treatment with doxorubicin plus cisplatin.

**Acquisition, analysis, or interpretation of data:** All authors.

**Drafting of the manuscript:** Nomura, Aoki, Michimae, Mizuno, Nakai, Arai, Sasagawa, Ushijima, M. Saito, Tokunaga, Matoda, Takahashi.

**Critical revision of the manuscript for important intellectual content:** Aoki, Sasagawa, Sugiyama, Nakanishi, Watanabe, T. Saito, Yaegashi.

**Statistical analysis:** Michimae, Sasagawa, Tokunaga, Takahashi.

**Obtained funding:** Aoki, Sasagawa, Nakanishi.

**Administrative, technical, or material support:** Nomura, Aoki, Sasagawa, Sugiyama, Watanabe, T.

Saito.

**Study supervision:** Sasagawa, Sugiyama, Watanabe, T. Saito, Yaegashi.

**Conflict of Interest Disclosures:** Dr Aoki reports grants from Chugai Pharmaceutical, Sanofi, Taiho Pharmaceutical, and Takeda Pharmaceutical, as well as personal fees from AstraZeneca, Bristol-Myers Squibb, Chugai Pharmaceutical, Janssen Pharmaceutical, Kyowa Hakko Kirin, MSD, Nippon Kayaku, Ono Pharmaceutical, Taiho Pharmaceutical, Takeda Pharmaceutical, and Yakult Honsha. Dr Ushijima reports grants from AbbVie, AstraZeneca, Chugai Pharmaceutical, Eisai, Kaken Pharmaceutical, Mochida Pharmaceutical, MSD, Ono Pharmaceutical, Taiho Pharmaceutical, Takeda Pharmaceutical, and Tsumura, as well as personal fees from AstraZeneca, Kaken Pharmaceutical, MSD, and Tsumura. Dr T Saito reports grants from the Japan Agency for Medical Research and Development, National Hospital Organization, Chugai Pharmaceutical, Nippon Kayaku, Taiho Pharmaceutical, and Yakult Honsha, as well as personal fees from Covidien Japan, Eisai, Hisamitsu Pharmaceutical, and Roche Diagnostics. No other disclosures are reported.

**Funding/Support:** This work was supported by the Health Labour Sciences Research Grant. The Japanese Gynecologic Oncology Group was supported by unrestricted grants from AstraZeneca, Asuka Pharmaceutical, Bristol-Myers Squibb, Chiyoda Technol Corporation, Chugai Pharmaceutical, Daiichi-Sankyo, Eisai, Fuji Pharma, Janssen Pharmaceutical, Kaken Pharmaceutical, Kyowa Hakko Kirin, Nippon Kayaku, Ono Pharmaceutical, Roche Diagnostics, Sanofi-Aventis, Sawai Pharmaceutical, Shionogi, Shiseido, Taiho Pharmaceutical, Yakult Honsha, and Zeria Pharmaceutical.

**Role of the Funder/Sponsor:** The funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

**Data Sharing Statement:** See Supplement 3.

**Japanese Gynecologic Oncology Group:** The following Japanese Gynecologic Oncology Group institutions participated in this study: Keio University, Aichi Cancer Center Hospital, Kindai University, Kitasato University, Niigata Cancer Center Hospital, Kurume University, Iwate Medical University, The Jikei University, Tohoku University Hospital, Cancer Institute Hospital of the Japanese Foundation for Cancer Research, St Marianna Medical University Hospital, National Defense Medical College, Tokai University, Kansai Rosai Hospital, Shikoku Cancer Center, Kyoto University,

Hokkaido University, Yamagata University, Kyushu Cancer Center, Fujita Health University, Saitama Social Insurance Hospital, Osaka City General Hospital, University of the Ryukyus, Osaka International Cancer Institute, Shizuoka Cancer Center, Kure Medical Center, National Cancer Center Hospital, Tottori Prefectural Central Hospital, Saitama Medical University International Medical Center, Hiroshima University, Niigata University, Jichi Medical University, Oita University, Toho University Ohashi Medical Center, Hokkaido Cancer Center, National Kyushu Medical Center, Misawa Municipal Hospital, Hirosaki University, Dokkyo Medical University, JR Sapporo Hospital, Kosei Hospital, Kyushu University, Osaka Saiseikai Suita Hospital, Tottori University, Nagasaki University, Mitsui Memorial Hospital, Gifu University, Juntendo University Urayasu Hospital, Yokohama Municipal Citizen's Hospital, Nagasaki City Hospital, Hiroshima Prefectural Hospital, Tokuyama Central Hospital, Fukuoka University, Kumamoto University, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Kumamoto City Hospital, Hiroshima City Asa Citizens Hospital, Aichi Medical University, Dokkyo Medical University Koshigaya Hospital, JA Hiroshima General Hospital, Kochi Medical Center, Showa University Northern Yokohama Hospital, Nara Prefecture General Medical Center, Osaka Medical College, Saitama National Hospital, Tachikawa Hospital, University of Occupational and Environmental Health Japan, National Nishi Sapporo Hospital, Nara Medical University, University of Fukui, Hyogo Cancer Center, Saga University, Tokyo Medical Center, Yamaguchi Red Cross Hospital, Yamaguchi University, Tsuboi Hospital, Otaru General Hospital, Kagoshima City Hospital, Asahikawa City Hospital, Fukuyama Medical Center, Kobe Medical Center, Iizuka Hospital, Sendai Medical Center, Yamanashi Prefectural Central Hospital, Shiga University, Tokyo Women's Medical University, Kyoundo Hospital, Japanese Red Cross Shizuoka Hospital, Kindai University Sakai Hospital, Nasu Red Cross Hospital, Saiseikai Nagasaki Hospital, The University of Tokyo, The Jikei University Aoto Hospital, Hamamatsu Medical Center, Okazaki City Hospital, Akita City Hospital, Tokyo Dental College Ichikawa General Hospital, Yokohama City University, Wakayama Medical University, Oita Prefectural Hospital, Seirei Hamamatsu General Hospital, University of Yamanashi, Takamatsu Red Cross Hospital, Tokyo Women's Medical University Medical Center East, KKR Sapporo Medical Center, Tomishiro Central Hospital, Nagoya Daini Red Cross Hospital, Shimane University, Saiseikai Sanjo Hospital, Yamada Red Cross Hospital, Hiroshima City Hiroshima Citizens Hospital, Ashikaga Red Cross Hospital, Mie Prefectural General Medical

Center, The Jikei University Third Hospital, Hakodate Municipal Hospital, Okayama Saiseikai General Hospital, The University of Tokushima, and Fukushima Medical University.

**Additional Contributions:** We thank the patients for their participation in this study, as well as families of the patients, all investigators, and onsite personnel. We thank Ms Miwa Nonaka and Mr Masahiko Watanabe of the Japanese Gynecologic Oncology Group data center (Clinical Trial Coordinating Center, Kitasato Academic Research Organization, Kitasato University) for their role in data management.
