Abstract

A systematic study has been undertaken to assess how the milling atmosphere, in the processing of an ODS steel with nominal composition Fe-14Cr-0.3Y_2O_3 (wt. %), will affect the microstructure and mechanical properties of the resultant alloys. Batches of the steel were manufactured by a powder metallurgy route incorporating mechanical alloying, hot isostatic pressing, forging and heat treatment. Hydrogen or helium atmospheres were used in the mechanical alloying, with all other processing parameters remaining identical. Transmission electron microscopy (TEM) and Atom Probe Tomography (APT) show that both milling atmospheres promote a homogeneous dispersion of Y-rich nanoparticles in the final alloys, being smaller when milling in H. Previously reported mechanical characterisation of these alloys shows better mechanical response at high temperature for the alloy milled in a H. This

can be justified by the presence of smaller Y-rich nanoparticles together with the absence of bubbles, observed in the alloy milled in He.

1. Introduction

It is well known that oxide dispersion strengthened (ODS) ferritic steels show improved irradiation resistance, high-temperature mechanical properties and microstructural thermal stability, relative to equivalent non dispersion strengthened steels [1-6] These outstanding features make them suitable candidates to be used as structural materials for advanced fission and fusion applications. The overall performance of these materials depends on their microstructure, in particular their grain size distribution and the oxide nanoparticle distribution; which themselves depend on composition and processing conditions [7-9]. The standard process to manufacture ODS alloys is by powder metallurgy followed by various thermomechanical treatments [10-13]. Mechanical alloying of ODS alloys is usually performed in a protective atmosphere to prevent oxidation; Ar gas has been widely used, but mechanical alloying in He or H atmospheres has been found to result in improved mechanical properties in the final consolidated material [14-16]. All of these milling atmospheres effectively prevent material oxidation during the manufacturing process, however, bubble formation was observed in the final material when Ar or He had been used in the powder milling [17, 18]. The presence of such bubbles is detrimental to the mechanical properties [3, 19] and should be avoided. On the other hand, no bubbles have been observed in consolidated ODS material when milling in H [20]. Furthermore, no deleterious hydrides formation was detected in that case.

In the present work, ODS alloys based on Fe-14Cr (wt. %) have been produced by

mechanical alloying in He or H atmospheres followed by hot isostatic pressing, and the resulting microstructures of these ODS alloys have been characterised.

2. Experimental procedure

The target composition of the manufactured alloys was Fe-14Cr-0.3Y_2O_3 (wt. %). Elemental Fe (99.7% pure) and Cr (99.8% pure) powders were supplied by Alfa – Aesar; powder particle sizes were < 10 μm and < 5 μm, respectively. They were blended with nanosized Y_2O_3 powder supplied by Nanophase Technologies (99.5% pure, particle size < 50 nm). The powder blends were mechanically alloyed in a Fritsch Pulverisette 6 planetary ball mill at 300 rpm and ball-to-powder ratio = 10:1 for 60 h, under pure He or H atmospheres. The milling atmosphere was the only difference between the processed alloys, keeping all other processing parameters identical. The alloyed powders were canned in 304 stainless steel cans (42 mm diam. × 57 mm height), degassed at 550°C in vacuum (p < 10^{-3} mbar) for 24 h and vacuum sealed. The canned powder batches were consolidated by hot isostatic pressing at 1100°C and 200 MPa for 2 h. The consolidated billets were forged at 1100°C, obtaining ∼ 12 mm × 12 mm × 170 mm bars, which were finally heat treated at 850°C for 2 h. To simplify the nomenclature in the subsequent presentation and discussion of results, the alloys will be referred to as 14YET and 14YHT, corresponding to He and H milling atmospheres, respectively.

The microstructure of these materials was investigated by transmission electron microscopy (TEM) and Atom Probe Tomography (APT). 3 mm disks were extracted from the bulk materials to prepare TEM samples. A TENUPOL 5 twin-jet polisher with a solution of 5% vol. perchloric acid + 95 % vol. methanol at − 40°C, typical for ferritic-martensitic and ODS steels sample preparation [21, 22], was used for electropolishing. Additional cleaning for 5 min in a plasma cleaner was applied prior to each TEM session. Bright field TEM images and

microdiffraction patterns were obtained in a JEOL 3000F microscope operated at 300 keV. Energy-filtered TEM (EFTEM) maps were obtained with a JEOL 2200MCO prototype microscope equipped with two spherical aberration (Cs) correctors and a Ω filter. EFTEM Y maps were acquired in the low loss region using the $N_{2,3}$ edge (onset at 26 eV). The EFTEM data were processed after acquisition using multivariate statistical analysis (MSA) [22]. Atom Probe Tomography samples were cut from the bulk materials in rod shape $\sim 0.5 \times 0.5 \times$ 20 mm and then subjected to a conventional two steps electropolishing process [23]. First, a rough polishing was performed by a double-layer method in which the specimen is repeatedly dipped into a layer of electrolyte (25% vol. perchloric acid, 75% vol. acetic acid) on top of an inert liquid (Galden^{TM} solution, perfluorinated polyether PFPE) applying a DC voltage of 15 V which was reduced to 10 V as the specimen area reduced to a circular necked region and then split into 2 parts. Each of these parts was subjected to a micropolishing process in which the specimen is repeatedly pushed through a gold loop that holds a drop of electrolyte (2% vol. perchloric acid, 98 % vol. 2-butoxyethanol). A DC voltage of 8 to 5 V is applied until the specimen's end is suitable for atom probe analysis, i. e. having a radius of curvature at the apex around or below 100 nm .

The APT analysis was carried out in a CAMECA Instruments LEAP® 3000X-HR operating in laser pulsing mode. An APT specimen base temperature of 30 or 50 K was used with a laser energy of 0.3 – 0.4 nJ at a repetition rate of 200 kHz. Data sets containing 20 – 25 million of ions were obtained, and data were reconstructed and analysed using IVAS 3.6.6 commercial software [24].

3. Results and discussion

3.1. Microstructural characterisation

3.1.1. TEM analysis

Fig. 1-a) shows the microstructure of the 14YET alloy. Nanoparticles are distributed mostly within grains, and also pinning grain boundaries and dislocations. Particle diameters are all less than 30 nm, with most of the particles less than 10 nm in diameter. The number density of visible particles was quantified in three regions; values found were: 0.10 ± 0.02, 1.0 ± 0.2 and 1.5 ± 0.3 ($\times 10^{23}$ m^{-3}).

An EFTEM Y N$_{2,3}$ map from the same region displayed in Fig 1-a) can be seen in Fig. 1-b), demonstrating that the nanoparticles are Y-rich. A detailed TEM study of this same alloy can be found in [18] and [25], in which a Y-O rich core and a Cr rich shell structure was found to be present in the majority of the particles, at least for the studied regions. Nanovoids of ~ 5 nm size, which might contain gas atoms derived from the milling atmosphere, were found in this alloy [18]. These nanovoids are not apparent in Fig. 1 as, due to their small size, they are only viewed out of focus. In the regions of study, most voids are found next to the particles. The microstructure of the 14YHT alloy is shown in Fig. 2-a). A fine dispersion of nanoprecipitates is found inside grains. All particles are below 30 nm in diameter, with mean diameter = 8 ± 6 nm. The number density of visible particles was determined in three regions; values found were 0.12 ± 0.02, 4.7 ± 0.9 and 9 ± 2 ($\times 10^{22}$ m^{-3}). The EFTEM analysis shown in Fig. 2-b) shows that the nanoparticles are Y-rich. Additional TEM observation of this same alloy is described in [20]. Fig. 3 shows HRTEM images of several of the nanoparticles found in the 14YHT sample. The particle displayed in Fig.3-a) was indexed as orthorhombic YCrO$_3$ viewed down zone axis [011]. The particle displayed in Fig.3-c) was indexed as body-centred cubic (bcc) Y$_2$O$_3$ viewed down zone axis [112]. These TEM observations did not identify the presence of nanovoids in this material; though, positron annihilation spectroscopy has revealed the presence of vacancy type defects in this same alloy [26, 27].

3.1.2. APT analysis

The mass spectra obtained by APT for the 14YET and 14YHT alloys was almost identical for both materials and produced a very similar respective measurements of the overall bulk composition. These results are displayed in Table I together with the nominal composition values. Ion maps for 14YET and 14YHT are displayed in Figs. 4 and 5, respectively. Both samples show a homogeneous distribution of Cr in the iron matrix, while Y, Y-O and Cr-O ions appear clustered and evenly distributed within the analysed volume.

A cluster analysis based on the maximum separation method [28] was applied to define clusters. This method assumes that the distance between two solute ions (Y, Y-O and Cr-O in this case) within a cluster is smaller than the distance between two solute ions found elsewhere in the reconstructed volume. Hence, in this approach, all pairs of solute ions with a separation less than the user-defined distance d_{max} are assigned to be in the same cluster. To avoid the inclusion of random clusters, i.e. clusters occurring by statistical fluctuations in a nominally homogeneous distribution of solute in the analysis, a minimum number of ions in the cluster, N_{min}, is imposed. This N_{min} parameter filters the analysed data by removing all clusters consisting of less than N_{min} atoms. The cluster selection parameters for each alloy were optimised for detection of clusters according to the criteria developed in [29]: $d_{max} = 1.6$ nm and $N_{min} = 7$ were used to analyse data from the 14YET alloy; $d_{max} = 1.3$ nm, $N_{min} = 12$ for 14YHT. 265 and 236 clusters were found, respectively, in the analysed volumes of 14YET and 14YHT.

The cluster size was calculated in terms of the Guinier diameter, i.e. twice the Guinier radius [30]. Figs. 6-a) and b) show the cluster size histograms obtained for the 14YET and 14YHT alloys, respectively. Table II presents a summary of the statistical analysis of the measured cluster size, number density and volume fraction for each alloy. It can be seen that there is less dispersion in particle size for the 14YHT than for the 14YET alloy. The mean particle size for 14YHT is 4% smaller than for 14YET; also, the experimental error is 35% smaller in

14YHT than in 14YET. In agreement with TEM observations, the number density of clusters in the 14YET alloy was higher than in the 14YHT alloy.

Best-fit ellipsoids were used to define the shape of the clusters. The smallest, middle and largest characteristic lengths of the best-fit ellipsoids can be used to calculate the oblateness (smallest characteristic length / middle characteristic length) and the aspect ratio (middle characteristic length / largest characteristic length) of the clusters. Oblateness and aspect ratio measurements for each cluster for both alloys are shown in Fig. 7; this figure also indicate how the combination of oblateness and aspect ratio can be used to define the cluster shape as sphere, rod, lath or disc [31]. In both alloys, most of the clusters tend towards a spherical shape, but this tendency is somewhat more pronounced in the 14YHT alloy than in 14YET. (Table III).

The chemical composition of the clusters was also analysed by APT. Figs. 8-a) and 8-b) show the Y, O and Cr content in the clusters vs their Guinier diameter for 14YET and 14YHT, respectively. Y and O content, or Y/O ratio, tends to be random for the smallest clusters found in both alloys, but compositions stabilize above a threshold size. In 14YET (Fig. 8-c)), Y/O ratio = 1.17 ± 0.12 for Guinier diameter larger than 4.08 nm and, in 14YHT (Fig. 8-d), Y/O ratio = 1.04 ± 0.10 for Guinier diameter larger than 3.82 nm.

Cr was not always present in the clusters. In the 14YET sample, 52 out of 265, i. e. 20% of the clusters characterised in the analysed volume, did not contain Cr. The Cr content in the other clusters was between 0.4 and 8.3 at. %. In the 14YHT sample, 24 out of 231 clusters (10% of them) did not contain Cr. The Cr content in the other clusters was between 0.5 and 7.4 at. %. No correlation between the Cr content and the cluster size could be established in this case (Figs. 8-a) and b)).

Cr-O ions appear to surround the clusters rather than being incorporated in the core. In both alloys, most of the Y rich clusters were enclosed by Cr-O isoconcentration surfaces

(isosurfaces); an example of this can be seen in Fig. 9. The isoconcentration surface values

for Cr-O (0.3 at. %) and Y ions (1.0 at. %) displayed in Fig. 9 were selected as those visually

enclosing the majority of the perceptible clusters in the 3D reconstructed volume. Cr-O

isosurfaces were usually irregular in the 14YET sample (Fig. 9-a), but they generally

replicated the Y-rich cluster shape in the 14YHT alloy (Fig. 9-b).

3.2. Mechanical properties

The mechanical properties of the 14YET and 14YHT have been reported in [10] and [20],

respectively. In those studies, tensile tests were performed on flat tensile specimens (20 mm

gauge length × 3 mm width × 1 mm thickness) at a constant crosshead rate of 0.1 mm/min at

25, 400, 500, 600 and 700°C. A flow of pure Ar was supplied while testing above room

temperature in order to prevent surface oxidation.

Fig. 10 displays the stress-strain curves of both alloys at different test temperatures, from

room temperature up to 700°C. Table IV summarizes the mechanical properties (yield

strength, ultimate tensile strength, uniform elongation and total elongation) in that

temperature range. Both alloys show a similar tendency vs. temperature. Individual

yield-strength values for 14YHT are lower than 14YET at room temperature and at 600°C,

almost the same at 400°C and higher than 14YET at 500 and 700°C. The yield strength value

at the highest tested temperature, 700°C, in the 14YHT alloy is 25% higher than in the

14YET alloy.

As described in section 3.1.1, nanovoids of ∼ 5 nm diameter were observed by TEM in the

14YET alloy; these might contain gas atoms derived from the milling atmosphere. Such

nanovoids might coarsen with temperature according to the observations made in [32], in

which bubbles present in a nanostructured ferritic alloy coarsen following thermal treatment

at a temperature of 750°C for 10 h and 100 h. This might account for the decrease in strength

in this alloy type with increasing temperature.

No nanovoids were observed by TEM in the 14YHT, but positron annihilation analysis revealed the presence of vacancy type defects in this alloy, which were stable at temperatures up to 750°C [26]. The stability of these defects even at high temperature, together with the presence of a higher density of smaller nanoparticles in the 14YHT alloy might account for its better mechanical performance at high temperature.

4. Conclusions

In this work, two alloys with nominal composition Fe-14Cr-0.3Y_2O_3 (wt. %) have been produced by a powder metallurgy route consisting in: mechanical alloying of Fe and Cr elemental powders with nanometric Y_2O_3 powder in pure He and H atmospheres, canning and degassing, hot isostatic pressing, forging and heat treatment. The microstructure and mechanical properties of the obtained alloys have been characterised. The following conclusions were realised:

- Complementary TEM and APT revealed the presence of Y rich nanoparticles, mostly inside grains in both alloys but, in the 14YET alloy they were also pinning grain boundaries and dislocations. From APT, the mean cluster size and its standard deviation were found to be smaller in the 14YHT than in the 14YET alloy.

- TEM and APT both demonstrate the cluster number density to be higher in the 14YET alloy than in 14YHT.

- The shape of the clusters is mainly spherical, but a higher fraction of spherical nanoparticles was found in the 14YHT alloy by APT.

- TEM and APT both found the nanoparticles to mainly contain Y and O; Cr was found in some, but not in all of them.

- Cr-O rich isosurfaces could be defined surrounding most of the clusters in both alloys

by APT. The shape of these isosurfaces replicated the geometry of the Y-rich nanoclusters in the 14YHT alloy, but they displayed more irregular shapes in the 14YET alloy.

- The yield strength value at 700°C, the highest tested temperature in this study, is higher for the 14YHT alloy. It can be due to the presence of nanovoids observed by TEM in the 14YET alloy, which might coarsen with temperature. The presence of smaller nanoparticles in the 14YHT might also contribute to this better mechanical performance.

Table(s)

Table I. 14YET and 14YHT average chemical composition in bulk from APT analysis together with the nominal composition.

Ion	Nominal value (at. %)	14YET APT (at. %)	14YHT APT (at. %)
Fe	84.76	86.317 ± 0.010	86.064 ± 0.008
Cr	14.87	12.625 ± 0.009	12.751 ± 0.008
Y	0.15	0.101 ± 0.001	0.103 ± 0.001
O	0.22	0.254 ± 0.001	0.306 ± 0.001
C	- - - -	0.007 ± 0.001	0.003 ± 0.000
N	- - - -	0.116 ±0.001	0.093 ± 0.000
Other	- - - -	0.582 ± 0.001	0.681 ± 0.001

Table II. Cluster size summary, number density of clusters and volume fraction of clusters in the 14YET and 14YHT alloys.

	Guinier diameter			Number density of clusters ($\times 10^{23}$ nm^{-3})	Volume fraction of clusters
	Range (nm)	Median (nm)	Mean value (nm)		
14YET	1.24 - 8.94	2.94	3.18 ± 1.04	5.7	0.6%
14YHT	1.69 - 6.80	2.98	3.06 ± 0.68	3.3	0.2%

Table III. Cluster shape summary for 14YET and 14YHT alloys.

	Number of analysed clusters	Spherical	Disc shaped	Rod shaped	Lath shaped
14YET	265	84.5%	7.6%	6.8%	1.1%
14YHT	236	93.1%	5.2%	1.7%	0.0%

Table IV. Mechanical properties summary for 14YET and 14YHT alloys, from [10] and [24].

	Yield strength (MPa)		Ultimate tensile strength (MPa)		Uniform elongation (%)		Total elongation (%)	
Temperature	14YET	14YHT	14YET	14YHT	14YET	14YHT	14YET	14YHT
RT (25°C)	1170	1085	1265	1169	5.0	5.1	7.0	6.7
400°C	805	816	869	880	5.2	5.7	9.0	8.6
500°C	710	751	778	804	3.7	6.6	7.3	11.6
600°C	336	272	407	350	8.3	15.0	19.8	48.1
700°C	176	218	242	294	11.1	8.2	13.3	10.4
